Tariff Policy.—The pre-War tariff might be characterised as a Protectionist one, but it granted practically no protection to grain-growing. Post-War legislation has provided agricultural protection and, with the elimination of the special facilities formerly existing between Russia and Finland, the grain duties now established may be expected sensibly to influence agricultural conditions. The new policy made no radical change in the tariff on manufactured goods, but sought to promote a more scientific distribution of duties and to secure as large an income as possible to the state. But the revision of the tariff was not completed in 1925. Commercial agreements have been concluded with France (July 13 1921), Great Britain (Dec. 14 1923), the United States (May 2 1925) and several other countries during the post-War period. Finland's prohibitory legislation in regard to wines and alcoholic liquors in some cases made the task of negotiation a difficult one. To Estonia Finland granted (Oct. 29 1921) considerable fiscal concessions not granted to any other Power, but Estonia plays a very small part, about 1% in Finnish trade.

Social Legislation.—An active policy aiming at improving the position of the numerous landless agricultural population had been set on foot some time before the War. After gaining her independence Finland adopted laws which with certain limitations gave tenants the opportunity of purchasing their holdings at a price below their value in the open market, and a large number of tenants have been turned into small owners. Recent social legislation further includes the adoption of an eight-hour day. Financial considerations have limited the scope of actual legislation for social insurance, but workmen's compensation for accidents has been put on a new and more comprehensive basis by legislation of 1917 and 1925.

The co-operative movement has made considerable progress in Finland. This holds true of consumers' co-operation as well as of several branches of agricultural co-operation. The central co-operative butter export association "Valio" has carried on by far the greater part of the total exports of butter and has, no doubt, been of great service in improving and standardising the quality of dairy produce. The butter exports mainly consist of high grade ware, and the grading takes place under state control. (A. My.)

INLAY, ROBERT BANNATYNE FINLAY, 1ST VISCOUNT, 42–), British lawyer and politician, was born at Edingh July 11 1842. He was educated at Edinburgh Academy University, and graduated in medicine. In 1867 he was ed to the bar, in 1882 becoming a Q.C. and a bencher of the ddle Temple. He was elected as Conservative member for erness Burghs in 1885, and held this seat until 1892. In 1895 regained the seat, and was made Solicitor-General in Lord sbury's Govt., when he was knighted. In 1900 he became orney-General, remaining in the Govt. until the Conserve defeat of 1906. In 1910 he was elected M.P. for Edingh and St. Andrews universities, and in 1916, on the forma of Mr. Lloyd George's Govt., became Lord Chancellor and e peer. He retired in 1918, and in 1919 was created a visnt. In 1920 he was appointed British member of the Perent Court of Arbitration at The Hague, and in 1921 became a nber of the Permanent Court of International Justice established by the League of Nations. From 1902 to 1903 he was lord or of Edinburgh University.

INNISH LITERATURE (*see* 10.386).—Several of the writers innish mentioned in the earlier article have since died. P. ander died in 1913, after having completed his translation of kespeare's plays in the previous year. Karl Bergbom, who e the Finnish National Theatre and was its first manager, in 1906. Of lyric poets, J. H. Erkko died in 1906 and Arvi es in 1915. The old peasant writer, P. Päivärinta, died in , and his younger colleagues, Kauppis Heikki, in 1920 and eijonen, in 1924. S. Ingman later took the name of "Ivalo" abandoned the realistic description of present-day life for historical novel. S. Alkio became a politician and leader of Agrarian party, being several times a Cabinet Minister. d Järnfelt, in his works published during this period, man to shake off the preponderating influence of Tolstoy.

rose.—The greatest writer of Finnish prose literature, Ju Aho, died in 1921. Amongst his later works mention may nade of *Rauhan erakko* (1916), in which the writer protests nst militarism, *Muistatko* (1920), an autobiographical study ildhood, and *Lastuja VIII.*, a collection of essays on salmon salmon fishing, dating from the year 1921.

he most notable of the younger writers were Johannes Linkoski (1869–1913) and F. E. Sillanpää (b. 1888). Linnani achieved European renown by his novel *Laulu tulipunai kukasta* (1905)—"The Song of the Blood-Red Flower"— h has been translated into a number of languages. His best from an artistic point of view is *Pakolaiset* (1908). Sillanpää written several collections of short stories dealing with peaslife, and one great novel dealing with the time of the Red rrection, which is an important document of social history. strength lies in psychological descriptions of subconscious es. No other Finnish writer has been so successful in depicting the atmosphere in which the peasant lives his everyday life. Teuvo Pakkala (1862–1925) made his name by realistic studies of proletarian life, short stories and plays about the peasantry, and studies of children, which show great psychological insight. Joel Lehtonen (b. 1881), like Sillanpää, wrote novels inspired by the Red insurrection. The novels of Ilmari Kianto (b. 1874) on the peasantry are flavoured with satire. Kyösti Vilkuna (1879–1922) produced novels, short stories and plays. Among other things, he described the part which he himself played in the legal struggle against Russia and in the events leading up to the war of independence.

Of the numerous women writers, the following deserve mention: Aino Kallas (b. 1878), short story writer, one of her volumes, *The White Ship*, being published in English in 1924. The wife of an Estonian scientist and diplomat, she obtained an intimate knowledge of Estonian life, which forms the subject of many of her stories. Mailo Talvio (b. 1871) wrote numerous novels concerning life among the peasants and higher ranks of society. Maria Jotuni (b. 1880) possesses a realistic power and a robust humour which inform all her stories, novels and comedies. L. Onerva (b. 1882) is best known for her lyric poetry, but also wrote fiction and plays.

Poetry.—Among the poets writing in Finnish, Eino Leino (1878–1925) was unusually productive. He published dramas in prose and verse, novels, short stories, literary studies and numerous volumes of lyric poetry. His most successful works are his *Helkavirsiä*, historic poems in ballad form of a strongly national colour. Leino has also translated Dante's Divine Comedy into Finnish blank verse. Larin Kyösti (b. 1873) was another prolific writer, who achieved a well-deserved popularity by his popular poetry. The lyrical poetry of Otto Manninen (b. 1872) is highly esteemed by connoisseurs. Manninen did invaluable work as translator of the Iliad, Odyssey, Molière's metric comedies and other works. V. A. Koskenniemi (b. 1885), professor of literature at the Finnish University of Turku (Åbo) published numerous volumes of poetry. He lacks the spontaneity of Leino and Larin Kyösti, but is unsurpassed in Finnish literature as the creator of a lofty style, his favourite verse forms being the sonnet and the elegy.

Literature in Swedish.—The Swedish literature of Finland includes a number of poets who have gained reputations both in their own country and in Scandinavia. Mikael Lybeck (1864–1925) achieved his first successes with lyric poetry, but abandoned verse for prose during the last 20 years of his life. His short stories, novels and dramas are highly esteemed by literary critics, though they have not achieved any widespread popularity. Bertel Gripenberg (b. 1878) is the chief master of form among the poets writing in Swedish. He has handled many different kinds of verse with great skill, but specially favours the sonnet. The characteristics of his first volumes were dark passion, sensualism, pessimism and an aristocratic romanticism, but he has also found words to sing of the Finnish wildernesses, and has written patriotic lyrics, inspired by the Red insurrection and the War of Independence, in which an echo of Runeberg's heroism may be heard. Jakob Tegengren (b. 1875) writes in an elegiac key, and descriptions of nature occupy a large part of his works. In his later volumes a religious tendency is visible. Hjalmar Procopé (b. 1868) has written a few dramas, but is best known as a lyric poet. Arvid Mörne (b. 1878) sings of the archipelago, peasant life and the scenery of the Swedish-speaking districts in the south of Finland. He is the poet of the sea, more than any other of the writers in Swedish. But Mörne's writings also reflect his deep, radical opinions. He was ardently interested in social reform and the movement for popular education. In his later works, however, this spirit has given place to a subdued resignation. Mörne also achieved success as a dramatist and novelist.

Emil Zilliacus (b. 1878) published some highly appreciated collections of lyrical poetry. Jarl Hemmer (b. 1893) is the most lyrical and spontaneous of the Swedish poets of Finland. His poetry still preserves something of the melodiousness characteristic of Topelius's lyrics. Hemmer's verse has a winning, youthful charm which yet does not preclude the expression of loftiness of thought. He also wrote a play, short stories and a novel dealing with the time of the War of Independence.

Runar Schildt (1888–1925) was the most eminent writer of Swedish prose in Finland. His short stories are characterised by a highly developed style, penetrating psychological insight and a humane, tolerant view of life. The subjects of some of them were taken from the War of Independence and the Red insurrection. Schildt was also a very successful dramatist. Vers libres and expressionist prose also found enthusiastic, and in some cases, gifted champions among the writers of Finland, both Swedish and Finnish.

Bibliography.—Werner Söderhjelm, *Karl August Tavaststjerna*, 2nd ed. (1913); *idem, Johannes Linnankoski* (1918); Gunnar Castrén, *Juhani Aho*, 1–2 (1922). (All these are in Swedish.) Anders Donner and others, *Finland, Land, folk, rike* (1923–5). (English edition in preparation.) (Y. H.)

FIRE CONTROL: *see* GUNNERY, NAVAL.

FIRE PREVENTION (*see* 10.401).—Steadily mounting fire losses, particularly in North America, have greatly stimulated efforts looking toward fire prevention. Fire losses of created resources in the United States increased from $447,886,677 in 1920 to $548,810,639 in 1924. The latter figure exceeds the loss in 1906, the year of the San Francisco earthquake and fire, although in 1924 there was no great single conflagration. In Canada, the destruction of created resources increased in the same period from $27,600,000 to $33,300,000.

I. IN NORTH AMERICA

In forest fires, also, similarly excessive losses are sustained by the United States and Canada. In 1924 (U.S.A. Forest Service estimate) 29,000,000 ac. of forested land in the United States were swept by fires, numbering 92,000 in all and entailing an actual money damage of $38,000,000, a figure exceeding by $18,000,000 the previous nine-year average. Owing to different statistical methods in use, an exact comparison with European experience is at present impossible. In general, however, it may be stated that a stricter surveillance is observed in the State forests in Europe, made possible in part by the smaller areas to be watched. The State forests of Finland, in the period 1911–21, were damaged to the extent of less than 1/20th of 1% annually. In Norway, during the period 1913–23, the average yearly damage amounted to about $24,000, the area burned being about 1,770 ac. each year. In the Prussian State forests, 1901–10, the average forest area devastated annually by fire was about 1620 acres. In the Bavarian State forests, 1900–12, an average of 103 fires burned about 380 ac. annually, which was less than 1/50th of 1% of the total forest land.

Prevention of Forest Fires.—The chief causes of forest fires are lightning, incendiarism, sparks from locomotives and carelessness of campers and of lumbermen. To check the operation of these factors the supervision of forest areas, particularly in the United States and Canada, has been instituted by governmental action. Fire lanes are cut through the forest to act as breaks and are kept open by fire rangers in the employ of the Government. Other duties with which fire rangers are charged include an oversight of lumbermen, campers and other visitors in forest areas with a view of inculcating carefulness. They are expected also to take immediate action in the event of fire. Watch towers and airplanes are used in detecting any incipient conflagration.

Buildings and Stock.—The causes of fires in buildings and stock are chiefly defective chimneys; carelessness in handling fire and inflammable material; defects in electrical installations, and exposure, that is, ignition from fires in adjacent property. The use of wooden shingles on roofs and, in mercantile districts, wooden window trim in otherwise fire-resistant buildings facilitates the spread of flames. Some of the more recent conflagrations (1910–25) in the United States have been those of Paris, Tex. (1,440 buildings, loss $11,000,000); Nashville, Tenn. (648 buildings, loss $1,450,000); Augusta, Ga. (680 buildings, loss $4,500,000); Atlanta, Ga. (1,938 buildings, loss $5,500,000); Berkeley, Cal. (584 buildings, loss $10,000,000); and Chicago, Ill. (loss $8,000,000). To reduce fire risk, automatic fire alarm systems, automatic sprinklers and chemical fire extinguishers have been installed in the larger buildings and to some extent, in private houses. Conveniently hung coils of garden hose with means for attachment to the water tap are also of value.

In order to educate the public to the importance of such measures, fire prevention is taught in the schools of many of the United States and a " fire prevention week " has been instituted to call attention to this form of preventable waste. Among the agencies in promoting fire prevention in North America is the National Fire Protection Association, which formulates standards of fire protection appliances, and co-operates with local associations in lessening fire risks, such as furthering the use of safe electrical installations. The National Board of Fire Underwriters maintains laboratories for the testing of materials and devices falling within the scope of its services, makes civic surveys covering elements entering into fire risks, and furnishes a model building code for the guidance of cities desiring one. The U.S. Chamber of Commerce, also, acting through a committee on fire waste, promotes special studies of fire-risk conditions in individual communities and urges such action as appears desirable. In most cities, desirability of action along the following lines has been indicated: (*a*) Competent inspection by the fire department; (*b*) a more general use of fire-resistive roof coverings, protected window and door openings and automatic sprinklers; (*c*) adequate ordinances governing the storage and use of explosives and inflammable substances; (*d*) adequate means for the conviction of incendiaries; (*e*) public education in the transmission of fire alarms and use of first-aid extinguishing devices. (F. H. W.)

II. IN GREAT BRITAIN

With the growth of cities and consequent risk of conflagration, fire prevention is a subject which has received much attention since 1910. Societies have been formed for the special consideration of the matter, and public bodies and insurance companies have given every possible assistance in devising means and methods for the prevention of fire. Great Britain is much behind in the matter of official regulation for fire prevention, and insurance companies have done more than the authorities by encouraging improvements in construction and the introduction of appliances such as automatic sprinklers, automatic alarms, fire doors, etc.

A large proportion of fires is due to carelessness. There is the thoughtless individual who throws away a match before the spark is out, without looking where it falls, and the careless smoker who leaves cigarette ends in close proximity to combustible material. The " no smoking " sign in factory and warehouse is often ignored, and the guilty individual fails to realise how his act is a menace to life and property. If notices prohibiting smoking in factories or other buildings are posted up, they should be rigorously enforced. Smoking should be prohibited in all factories, and the growing tendency to allow smoking in theatres and music halls should be strongly deprecated.

There has been a large increase in the use of highly inflammable liquids and material, and public attention should be called to the danger, both in the use and in the storage of these. Many hazardous processes in manufacture from a fire hazard point of view can be rendered innocuous by the precautions recommended by insurance companies. Apart from individual carelessness, fires are often caused through defective building construction, such as wooden joists or beams under hearths and entering flues, etc., insecure heating apparatus and defective lighting systems.

Precautions.—In large cities, building by-laws are fairly strict, but insurance companies have done more than the authorities to encourage improvements in construction. Party walls through and above the roof and fireproof doors, where communications exist between buildings, often keep a fire from spreading. Insecure stoves and flue pipes should never be allowed and proper fenders and guards for fireplaces are amongst the simplest preventatives. Electric light installations should be overhauled by experts from time to time, and fuse boxes should not be tampered with by people ignorant of their use. Gas brackets and all

ings should be securely fixed. It is the duty of each occupier
a building to watch for signs of defects, and either to report
m or have the defects remedied.

Many devices are in use for detecting fire, known as automatic
alarms. The general principle is that the heat generated by
re causes a metal to expand, making electric connection and
ing an alarm bell in motion. Automatic fire alarms may be
nected up direct with fire brigade stations, thus securing an
nediate turn-out to a fire. In spite of precautions, fires will
ur, and every means should be taken to summon assistance
extinguish the outbreak. Fire precaution is a natural step
r fire prevention. Every occupier of a building should know
exact position of the nearest fire alarm, so that the fire brigade
reach the scene without delay.

t is often said that the first five minutes at a fire is worth more
n the next four hours, and water should be at hand to put out
flames. Buckets of water or chemical extinguishers should be
very building. There are many extinguishers on the market,
e containing liquids, others powdered chemicals, but no class
ire extinguisher is a cure for all fires. The extinguishing agent
st have either the property of allaying heat or a blanketing
ct or a combination of both of these. Fire in ordinary com-
tible materials can be put out with water, but fires in oils,
ases, etc., must be put out with a blanketing agent. Certain
micals put a film or thin blanket over the liquid or material,
s excluding the oxygen long enough to allow the mass to
l below its burning point.

ireproof buildings, efficient fire brigades and adequate water
plies have all contributed to reduce fire waste, but special
ntion should be made of the protection offered by auto-
tic sprinkler installations. The installation of these is becom-
quite common, and they have proved in practice to be won-
fully effective. Automatic sprinklers consist of a head or
er-jet connected with water pipes, in which a pressure of
er is maintained, the head being released by the melting of
ler when there is sufficient heat generated by an outbreak of
and the water automatically plays upon the fire, quickly
duing it. In connection with the installation there is also a
gong, which automatically works with the opening of a
inkler head, and assistance is thereby summoned at once.

(E. M. M.)

ISCHER, EMIL (1852–1919), German chemist (*see* 10.426),
in Berlin July 15 1919.

ISHER, JOHN ARBUTHNOT FISHER, 1st Baron (1841–
o), British sailor (*see* 10.428). From 1910 until Oct. 1914
d Fisher remained in retirement, although Mr. Churchill,
at the Admiralty, constantly consulted him and it was on
her's advice that Jellicoe was designated admiral of the
nd Fleet in the event of war. (At the time of the Agadir
is, however, Fisher had expressed to Lord Esher and others
ng disapproval of the War Office plans engaging us in ex-
sive land operations in France.)

isher was recalled as First Sea Lord in place of Prince Louis
Battenberg in the critical days at the end of Oct. 1914. The
udacious" had been sunk, Cradock heavily defeated off
onel, German submarines were active and there was no
ctive blockade of Germany. Fisher took the responsibility
weakening the British fleet in home waters and detached
"Invincible" and "Inflexible" to engage von Spee, with
result that a complete victory was gained in the battle of the
kland Islands. To Fisher's boldness and realism again were
the new blockade policy and the laying of extensive mine
ls. The association between Churchill and Fisher was most
py until it was broken by the Dardanelles enterprise. Fisher
never liked it; his own preference was for a landing on the
st of Prussia and the employment of Russian troops against
heart of Germany. But he was persuaded by Churchill into
iescence.

hen, however, the first attempt to force the straits had
ed, and German submarines had made their appearance in
kish waters, and it seemed doubtful whether the demands of
French campaign would allow the British to send the necessary reinforcements to the army in Gallipoli, Fisher felt that he could no longer continue to countenance the project of forcing the Dardanelles. At the War Council of May 14 1915 he had declared that "he was against the Dardanelles and had been all along." Churchill afterwards told him that it was not fair to obstruct necessary measures at the Dardanelles and then when things went wrong to turn round and say "I told you so, I was always against it." Fisher replied "I think you are right—it isn't fair." That night Mr. Churchill in order to encourage the entry of Italy into the War on the side of the Allies gave instructions that four cruisers should go to the Mediterranean 48 hours before the time arranged, and the minute was signed "First Sea Lord to see after action." That was the first document seen by Fisher on beginning work as usual at four o'clock next morning. He resigned and never entered the Admiralty again. His resignation coinciding with the crisis about high explosive shells, brought down the already shaken Liberal Govt., and led to the formation of the first Coalition. The manner of his leaving the Admiralty became Fisher less than anything in his life, but his motives were neither personal nor unworthy. He felt that as things were he had lost his power of service; that he could only hamper the Dardanelles and be "unfair" to Churchill without influencing events in the direction which he felt was right.

Fisher did useful work later in the War as Chairman of the Inventions Board, and when he died on July 10 1920 and was buried in Westminster Abbey, the crowds felt that they were mourning the greatest British sailor since Nelson. Their reverence was the more remarkable because Fisher never commanded a fleet in action, nor, except the Falkland Islands, is any great victory at sea traceable to his direct inspiration. His enemies accused him of exaggerating the material side of naval power at the expense of the moral and intellectual. He was not good in the logical presentation of an argument; he thought pictorially and the sequence of his ideas expressed themselves in a series of verbal explosions. But his prescience amounted at times almost to second-sight, and he had a genius for the burning phrase that lights up the truth from within. The most amazing quality of the man was that as he grew older he became more radical and revolutionary in his ideas. To the old man in 1919 his own Dreadnought of 13 years was a symbol of effete tradition; his slogan "Sack the lot" was not the prosecution of a personal vendetta against the Admiralty chiefs, but expressed his conviction that though the spirit was eternal, its forms were only made to be broken. He wrote two volumes of memoirs: *Memories* (1919) and *Records* (1919), before his death; somewhat scrappy and disorderly in composition but full of his glowing vitality. Fisher married, in 1866, Miss Kate Broughton, by whom he had one son, Cecil, and three daughters.

FISHER, ANDREW (1862–   ), Australian politician, was born at Crosshouse, Kilmarnock, Aug. 29 1862, and began life as a coal miner. He emigrated to Queensland at the age of 23, and eight years later was elected to the Queensland legislature. He was elected to the Commonwealth Parliament in 1901, joined Mr. Watson's Labour Cabinet of 1904 as Minister of Trade and Customs, and became leader of the Labour party in 1907 on Mr. Watson's resignation. In 1908 he became Prime Minister, but his administration lasted only six months. At the general election in 1910, however, his party was returned with a sweeping majority, and he was Prime Minister for three years, during which period he tackled the question of imperial defence, adopted Lord Kitchener's report of 1909 and passed a measure establishing universal military training. His Ministry fell in 1913, but at the election of Aug. 1914 he was again returned to power and gave Australia a vigorous lead in the early days of the World War. At the end of 1915 he resigned and took up the high commissionership vacated by Sir George Reid. This office he held until 1921.

FISHER, HERBERT ALBERT LAURENS (1865–   ), British man of letters and politician, was born in London March 21 1865. He was educated at Winchester and New College, Oxford, being elected in 1888 to a fellowship at the latter college, where he lectured for some years. He earned recognition as a scholarly historian, and in 1911–2 was appointed Chichele lecturer in modern history at Oxford. He was also a member of the royal commission on the public services of India (1912–5). In 1912 he was appointed vice-chancellor of Sheffield University. In 1916, Mr. Fisher accepted the invitation to become Minister of Education in Mr. Lloyd George's Cabinet and was elected to Parliament for the Hallam division of Sheffield. In 1918 he was elected Liberal member for the English universities. An Education bill was introduced by him in Aug. 1917, which contained many important reforms (*see* EDUCATION). In Jan. 1925 he was elected warden of New College, Oxford, and he resigned his seat as member for the combined universities in Feb. 1926.

Among his books are *The Mediaeval Empire* (1898); *Studies in Napoleonic Statesmanship* (1903); *A Political History of England* (1906); *Bonapartism* (1908); *Life of F. W. Maitland* (1910); *The Republican Tradition in Europe* (1911); *Political Unions* (1911); *Napoleon Bonaparte* (1913); *The Common Weal* (1924), besides essays and review articles.

FISHER, IRVING (1867–), American economist, was born at Saugerties, N.Y., Feb. 27 1867. He studied at Yale (A.B., 1888), Berlin and Paris. At first he taught mathematics at Yale; but in 1895 was made assistant professor of political economy, and, in 1898, professor. He was editor of *The Yale Review*, 1896–1910. He served as chairman of many commissions dealing with public health, prohibition and labour. An authority on money inflation, he proposed that the purchasing power of the dollar be stabilised (*see* DOLLAR STABILISATION).

His writings include: *Mathematical Investigations in the Theory of Value and Prices* (1892); *A Brief Introduction to the Infinitesimal Calculus* (1897); *The Nature of Capital and Income* (1906); *National Vitality* (1910); *The Purchasing Power of Money* (1911); *Stabilising the Dollar in Purchasing Power* (1919).

FISHERIES (*see* 10.429).—Dealing first with British fisheries, it may be said that during the 20th century development has been rather slow, having been directed rather to the perfection of existing classes of boats and nets than to new inventions.

The otter is still the chief net for trawling from steam vessels. Its mouth must be given as wide a gape as possible, so that floats and other devices are being employed to prevent its upper rope from sagging so as to close its aperture; a third otter board is sometimes used in this position. The same trawl, but with reduced mesh, is also dragged to catch fish swimming near the bottom, particularly herrings; further development in midwater fishing in the deeper oceanic areas seems probable. Seining, or the surrounding of areas by netting so as to enclose the fish, a method extended by the Danes, is now generally pursued in all the shallower waters of the North Sea; it results in large catches, particularly of haddock and plaice, the fish arriving in less bruised condition than after the long haul of the sac-like trawl.

Surface Fishing.—Surface fishing methods show little change; they are now mainly practised by steam drifters, which follow the successive shoaling of herrings from the northwest coasts of Scotland in Jan. to the Shetlands and, down the east coast of Great Britain, to Lowestoft in October.

Trawling.—Steam trawlers varying up to 145 ft. in length have still further replaced sailing vessels, fleets of the latter only being maintained at Lowestoft (136 vessels), Brixham (90), Ramsgate (25), and Plymouth (12). Experiments in the utilisation of oil fuel are now proceeding. These changes mean the further concentration of the industry in large ports and under companies or big firms. The hake is now generally recognised as a table fish and is trawled as far south as the Moroccan coast to depths of 250 fathoms; this fishery, in association also with that of soles and skate, has resulted in important fishery developments in Milford Haven, Swansea and Cardiff. To the north, trawlers regularly fish in the Barents Sea and off Iceland, and trial voyages have been made from Hull to the Greenland banks (1925); otherwise there is little increase in the fishing area. The Norway haddock (*Sebastes*) is now regularly marketed at Aberdeen, and the sea bream and skate have generally found favour. In recent years the inshore fisheries have been greatly helped by a loan scheme of the Development Commissioners for the installation of motors in the smaller sailing craft; a further scheme on business lines for the insurance of inshore fishing craft has also been financed by the commissioners, thus giving the inshore industry the power to secure its capital. On other sides the production of sterilised ice is a development of importance, and an entirely efficient method of preservation by freezing in brine has been perfected, but not yet applied in Great Britain. The use of fish waste to form nutritive fish meals has been undertaken in the greater ports, and on the retail side fish-frying shops have so immensely increased that they form an important factor in the feeding of town populations.

EUROPEAN FISHERIES

European countries, bordering on the Atlantic, show in their high-sea fisheries similar changes to those of Great Britain and are serious competitors on most fishing grounds. Norway, in particular, has developed all its fisheries; its export trade of salt cod and other fish products is of importance. Russia, the oceanic fisheries of which have to some degree retrograded, has interfered on several occasions with British trawlers working off her northern coasts; here, as also off Iceland, Spain, Norway and Morocco the maintenance of the territorial limit of three miles is regarded by the British fishing industry as of vital interest. France shows development in all the fisheries of the Bay of Biscay, especially in sardines and tunny; her trawling fleet has increased and her larger boats still proceed on regular annual voyages to the Newfoundland banks and to Ireland. Spain and Portugal are more organised and have extended the catching power of their fisheries, but still confine their voyages to adjacent waters.

AMERICAN, ASIATIC AND AFRICAN FISHERIES

With increase of population the importance of fisheries is more widely realised, and, in North America, the United States and Canada have pursued an active policy of development in both fresh and salt waters; they export large quantities of canned and frozen salmon to Europe. Newfoundland is still mainly exporting salt-dried cod, not having as yet adequately exploited her large shoals of herring and her salmon.

Asia.—Japan shows advance in every direction, and New Zealand and various states of the Commonwealth of Australia are concerned with the exploitation of their fishing grounds.

Africa.—South Africa, which has extensive areas of suitable depths to the south and west, maintains a trawler fleet, while a crayfish fishery has been opened off Natal. Many trawlers were sold after the War to go to tropical countries, but so far systematic fishing in such waters by large power vessels has not proved profitable. The largest areas of suitable depths still almost unfished are between the Falklands and Patagonia and in that great bay to the east of the Malay peninsula. The "Discovery" expedition to south Georgia should throw light on the possibility of southern grounds, while the Malay Govt. has a research steamer on the stocks (1926).

THE INDUSTRY IN GREAT BRITAIN DURING THE WAR

In 1914 there were about 100,000 fishermen of all classes in Great Britain. Practically 40% of these at once joined the navy, while over 10% quickly responded to the urgent appeals of the military authorities. About 3,000 steam fishing vessels, trawlers and drifters in about equal numbers, were requisitioned for service, and many more were built for the same purpose. They were largely manned by fishermen recruited from those still fishing; often a requisitioned vessel carried her whole crew with her. They were employed in the Auxiliary Patrol, in mine-sweeping from the White Sea to the Straits of Marmora and in all operations necessary to keep the seas open for the operations of the British fleet, for the transport of troops and material to France, for the advent of forces from overseas colonies and the United States, and, above all, for the due arrival of food from every part of the world. The few vessels left continued fishing, and a system of fleets fishing in selected areas under the protection of their own guns and those of the navy was devised. The success of this was seen in the fourth year of the War, only 4 steam trawlers being sunk by enemy submarines as compared with 156 in the previous year. By the middle of 1917 there were only about 14,000 men still fishing, of whom over 10,000 were over age or unfit for service. Yet in the same year about 8 million cwts. of fish were landed; about 40% of the average annual catch for the 20 years preceding the War; the value, however, was nearly the same.

Arrangements were made whereby Belgian and Dutch fishing vessels were based on British ports. The shell-fish industry was fostered and developed. The deficiency in fish was further reduced by importation, particularly from Norway and Holland.

Reconstruction Problems.—The reconstruction of the industry after the War presented problems of peculiar difficulty owing to the rapid fall in the price of fish, while all commodities used in the industry remained at over double pre-War costs. The greatest difficulty of all was to preserve the herring fishery, which depended for its existence on the export of about 80% of its catch to Germany and Russia as brine-cured herring, thus differing from the trawl fishery, the output of which is absorbed by the home market. The fishermen concerned had taken an essential and vital part in national defence, and their industry was threatened with complete annihilation, the loss of its skilled craftsmen and the rotting of its boats. The government took over the finance, and thus practically the management of this fishery by the "herring guarantees" of 1919 and 1920. The cost of this bold and unprecedented action amounted to £1,712,675. It was eminently successful, for the industry, thus re-established, survived a disastrous seasonal fluctuation in 1921 and now again flourishes, aided by good subsequent years and a new export trade of fresh herrings to the Continent.

Administration.—The interests of the fishing industry are cared for by the fisheries department of the Ministry of Agriculture and Fisheries, by the Fishery Board for Scotland and by corresponding departments in Ulster and the Irish Free State. There is a series of local county Sea Fisheries Committees around the coasts of England and of Boards of Conservators of certain salmon rivers; they are responsible for local by-laws for their territorial waters and rivers, but any such can be disallowed by the central authority. There are practically no restrictive regulations to administer, the central departments being maintained to help and foster the industry in the interests of the state. The high seas outside territorial waters are open to the fishermen of all countries and supply about 96% of the British catch, the larger trawlers and drifters not being allowed to fish within territorial waters. Under powers sanctioned by Parliament in 1889, the Moray Firth was closed to British trawlers, but this regulation is not enforceable against the trawlers of other nations outside the three-mile limit. For the most part the government departments act as expert intermediaries in the interests of the industry with all the government offices concerned (Admiralty, Board of Trade, Foreign Office, etc.), with market authorities and with railways. Officers are stationed in all the larger ports to help and advise the fishermen and to keep the Ministry informed of current fishery matters. The organisation of the statistics relating to the industry has been mainly the work of the English Ministry, difficulties due to the necessarily rapid handling of the fish on arrival in ports having to be overcome by the devising of unobjectionable tests and checks of all sorts.

Scientific Investigations.—The Fishery Departments of England, Scotland and the Irish Free State have each a scientific division, and each has its own research vessel with headquarters respectively at Lowestoft, Aberdeen and Dublin. The Irish vessel is also used for local policing purposes, as also is a further vessel under the Lancashire and North Western Sea Fisheries Committee. Fisheries protection on the high seas is a function of the navy. Great Britain also maintains a staff of fish measurers, who go to sea on commercial fishing vessels. Something of the kind is done by other countries.

INTERNATIONAL INVESTIGATIONS

In 1902 the International Council for the Exploration of the Sea was organised, Denmark, Germany, England, Finland, the Netherlands, Norway, Russia and Sweden being signatories to an agreement for the pursuit of scientific research into all the waters off northern Europe. It naturally became inactive during the War, but was reconstructed in 1920, France then giving her adhesion. It now includes all the countries of western Europe except Germany and Russia. Each country according to its means maintains research vessels, and each works on a determinate scheme, settled at the annual meeting, at which the facts collected are discussed. The departments of Scotland and Ireland organised scientific divisions to carry on their share of the work, but that of England was managed until 1910 by the Marine Biological Association.

The International Council is divided into Statistical, Hydrographical, Limnological and Plankton committees, together with committees for the following areas: North Sea, Baltic Sea, Atlantic Slope, North Western (Iceland, Faroes, etc.), North Eastern (off Norway and Arctic), with, as their first care, to consider the practical fishery problems arising, or likely to arise, in their own areas. Its greatest accomplishment of recent years has been the organisation of the collection of statistics of all countries concerned on a uniform basis, the form adopted being largely that of the statistical branch of the Ministry of Agriculture and Fisheries.

Problems Investigated.—The main problem before the council is to trace to their causes the fluctuations to which statistics show that all the great fisheries are subject. To this end the council has organised a general programme of biological work for all its members, co-operative research, the results of which are generally published nationally. In Great Britain there was a fear that the areas of the principal fisheries were being overfished; the fish supposed of most importance here was the plaice, as to which there were no reliable statistics, while its life-history was little known. Consequently a large part of the research power of England and Scotland has been concentrated on this fish, and the depletion of the plaice fishery of the North Sea by overfishing almost to the limits of safety has been established.

Various remedies have been suggested and carefully examined, such as regulating the size of the mesh of nets employed, prohibiting the sale of undersized fish, and completely or partially enclosing some of the nursery grounds. The first, so far, has been found to be impracticable, as the trawl has to catch round as well as flat fishes, but experiments with a view to overcoming the difficulties are being made. The second would entail undesirable regulations and costly inspection. In respect to the third, the closure of the North Sea during the War formed a gigantic experiment, the catch by English vessels in this sea increasing from 24,000 tons in 1913 to 33,000 in 1920, but falling to 22,000 tons in 1923. The fall was clearly due to overfishing, as shown by steam trawler average daily catches of 2·1, 3·4 and 1·9 cwts. of plaice in the three years respectively. The difficulty of closing areas lies in the necessity of negotiating international agreements, as all desirable areas to be closed are outside the limits of territorial waters to the east of the North Sea.

Other notable reports of the International Council, which has its headquarters at Copenhagen, and of the British Fishery Departments deal with the natural history and growth of the herring, of the plaice and of the cod, the determination of the water movements of the North Atlantic, the deposits of the North Sea, the movements of certain fish as shown by marking experiments, and the transplantation of plaice to the Dogger Bank. A report of the English Ministry describes the gear employed in 1923 and a Report of a Treasury Committee published in 1908 in the evidence recorded gives a full account of nearly every aspect of the fishing industry as it then existed. The annual administrative reports of the English and Scotch departments should also be consulted.

The researches of the government departments concerned are also largely aided by the work of the staffs of scientific marine laboratories situated at Plymouth, Cullercoats, Millport and Port Erin, each of which has its public aquarium. These, while founded by private enterprise, are materially assisted by grants from the Development Commission, on the recognition of the well-known fact that economic results usually follow scientific researches. Of these the largest is Plymouth with special departments for zoology, physiology and fisheries; it is the property of the Marine Biological Assn., which in its *Journal*, by agreement, publishes the result of research from all the British marine laboratories.

STATISTICS OF THE INDUSTRY

The approximate total value of the sea fisheries catch of the countries of western Europe in 1922 amounted to £48,000,000 (British Is., 39·5%; France, 17·6%; Spain, 15·5%; Norway, 7·5%; Denmark, 5%; Holland, 4%; Portugal, 3·4%; Germany, 3·3%). Canadian fisheries in 1924 were $44,500,000 (Provinces: Atlantic, $17,500,000, Inland, $5,500,000 and Pacific $21,500,000); Pacific salmon, $13,000,000 and Atlantic lobsters, $4,000,000; over 60% was exported. The recorded values for the United States in 1923 were about the same, but the inland fisheries were $13,000,000; exports were $12,000,000.

Great Britain

	Catches		Craft Employed		Employment	
	Demersal fish cwts.	Principal Pelagic fish cwts.	1st Class	2nd Class	Regular	Irregular
1909–13 average	11,613,066	10,769,178	6,602	5,203	67,962	13,150
1920 .	12,573,805	8,333,991	5,581	6,227	61,683	10,925
1924 .	10,880,251	9,800,481	4,921	5,777	54,610	8,947

This table shows vividly the modifications which have taken place in the Fishing Industry of Great Britain during the period under review. The type of fishing-boat has also changed greatly. In 1913, 3,233 steam-boats (3,222 1st class and 11 2nd class boats) were employed. In 1924, the number was 3,087, of which 3,078 were 1st class. Motor-craft, however, increased from 842 in 1913 (335 1st class and 507 2nd class) to 4,311 in 1924 (1,192 1st class and 3,119 2nd class). Sailing craft in 1913 were 7,730 (3,045 1st class and 4,685 2nd class), while in 1924 they were 3,300 (651 1st class and 2,649 2nd class). Corresponding figures are not available from other countries where statistics are based on different data and collected by different methods.

FITZMAURICE-KELLY, JAMES (1857–1923), British man of letters, was born in Glasgow June 20 1857. Educated at St. Charles's College, London, he became Taylorian lecturer in Spanish at Oxford in 1902. From 1909 to 1916 he was Gilmour professor of Spanish language and literature at the University of Liverpool; and in 1908 and 1912 Norman MacColl lecturer at Cambridge University. During 1907 and 1908 he lectured for the Hispanic Society of America at various American universities and at London University. In 1916 he was appointed Cervantes professor of Spanish language and literature at the University of London, a post he held till his resignation in 1920. Among his numerous published works should be mentioned *The Life of Miguel de Cervantes Saavedra* (1892); an introduction to the editio princeps of *Don Quixote* (1898–9); a *History of Spanish Literature* (1898); *Cervantes in England* (1905); *Miguel de Cervantes: a memoir* (1913); *Cervantes and Shakespeare* (1916); *Góngora* (1918); and *Fray Luis de Leon* (1921). He edited among other publications, the *Oxford Book of Spanish Verse* (1913) and the complete works of Miguel de Cervantes Saavedra (1901–). He died at Sydenham, London, Nov. 30 1923.

FIUME (Slav "Rijeka" both meaning "the river"), a port on the Adriatic (*see* 10.449). As the only port of Hungary, Fiume had had little history, but the city sprang into world-wide notoriety and became a burning question after the World War. The question of Fiume even threatened to become the cause of a further war between Italy and Yugoslavia. The "secret" treaty of London of April 26 1915, which contained Italy's terms for entering into the War, assigned Fiume to Croatia, and Senator Tittoni (subsequently Minister of Foreign Affairs) informed the writer that Baron Sonnino who negotiated that treaty for Italy, never once asked for Fiume; had he done so at that time, he could have had it for the asking. This point is important, because the Italian Press afterwards blamed the Allies for "refusing" Fiume to Italy.

The Italian Claims.—The first Italian claim to Fiume was made by Sig. Bissolati immediately after his resignation from the Cabinet at the end of 1918. Baron Sonnino's inaction in this matter was due to the fact that in 1915 he had neither anticipated, nor desired, the total breakup of the Dual Monarchy, but wished, while annexing the purely Italian provinces of Austria, to leave Fiume to Hungary, instead of including it, as a future rival to Trieste and Venice, among the Italian ports at the head of the Adriatic. But in 1919 the official Italians demanded Fiume on the principle of "self-determination," because the majority of its inhabitants was Italian, and largely so if Fiume proper were separated from its Yugoslav suburb of Sušak on the opposite side of the rivulet, which had given to Fiume its name, and which the Slavs called simply Rečina, and the Italians "Eneo"—a poetical title for so prosaic a stream. That Fiume was in 1919 predominantly Italian is true, but the Italian element had immigrated within comparatively recent years; the very detailed description of Fiume about 1855 by Charles Lever (the British consul at Trieste) in his novel, *That Boy of Norcott's*, mentions Slavs and Hungarians but never Italians there.

Meanwhile, on Oct. 23 1918, Croat troops had seized Fiume and in Nov. there was a dual occupation, against which the Yugoslav national council protested, by Italian and Serbian troops, while Italian naval forces entered the harbour. The Serbian troops were, however, withdrawn and replaced by Americans, pending the decision of the Fiume question by the Peace Conference. The Italians' position was similar to that known in English law as "pleading inconsistent defences." They claimed North Dalmatia, overwhelmingly Slav by race, in virtue of the Treaty of London, which President Wilson repudiated, and Fiume in virtue of the Wilson principle of "self-determination."

The D'Annunzio Adventure.—They ultimately obtained Fiume, thanks to the raid made by Gabriele D'Annunzio, who mustered a body of men at Ronchi near Trieste, and on Sept. 12 1919 occupied the contested town. There despite official notes, he remained as "commandant," offering to a prosaic age the spectacle of a poet as governor, and surrounding a commonplace town with the glamour of his dithyrambic speeches. He drew up a constitution for the "Carnaro," as he called his miniature state, and soon Fiuman divorces became the fashion for Italians unable to dissolve their marriages at home. He delivered frequent speeches, and represented the oppressed nationalities of the whole world as looking to Fiume, "the holocaust city," for consolation in their affliction. He descended with his "legionaries" upon Zara and meditated an extension of his territories still farther southward. While successive Italian Governments gave him no official support, he received considerable sympathy from the Nationalist elements in Italy and was regarded with corresponding aversion by the Yugoslavs, whose prowess in the Middle Ages he had sung in a poem of encyclopaedic erudition at the outset of the War.

But when Signor Giolitti in 1920 became for the last time Premier and concluded the treaty of Rapallo with the Yugoslavs, he resolved to turn the poet out of Fiume, and that eminently common-sense politician did so by force. The "commandant's" official residence was bombarded by the "Andrea Doria," and he narrowly escaped the martyrdom which he had proclaimed for himself and his followers, a "holocaust" for his country. After the "heroic age" of his rule there came the prosaic interlude of his local rival, Sig. Zanella, who represented the autonomous, as opposed to the Italian National, party, and aimed at bringing about a good understanding with Yugoslavia. A *coup d'état* by *Fascisti* and "legionaries" took place in 1922; the Government offices were stormed; Sig. Zanella abdicated in favour of a "government of national defence," and was escorted over the frontier in an armoured car; Sig. Prodan, a local engineer, succeeded him, and annexation to Italy was proclaimed. Official Italy, however, acted with caution and persuaded Sig. Giurati, a *Fascistà* deputy, to decline the proffered post of "Civil Commissioner," while D'Annunzio from his retreat on the lake of Garda denounced the dissensions of Fiume, and refused to return and lead the Fiuman movement.

Negotiations between Italy and Yugoslavia.—Finally General Giardino became Governor, and Signor Mussolini made a serious attempt to come to terms with the Yugoslavs. The river had in the course of generations changed its course, forming a

Delta," as it was called, and thus rendering doubtful the boundary of Fiume towards Sušak. Both Italians and Yugoslavs laimed the "Delta." The smaller harbour, too, called in Hunarian times "Port Baross" after a former governor, but rehristened by the Italians "Porto Nazario Sauro" after one of he heroes of the War, was a matter of dispute, but by a letter written by Count Sforza, then Italian Minister of Foreign Afairs, a few hours after the signature of the treaty of Rapallo in Nov. 1920 it was ceded to Yugoslavia.

Even after the refusal of D'Annunzio (afterwards created by the Fascisto Government "Principe di Monte Nevoso"), bickerings till continued and the two rival races did their best to give one another economic pin-pricks and thereby nearly ruined the trade of the once flourishing port of Hungary. Thus, the Italian ailway time-table was so arranged that the trains did not connect at the frontier-station of Postumia, while the Yugoslavs topped their through railway service to Fiume altogether, so hat the traveller from Fiume into Yugoslavia had to drive across he wooden bridge into Sušak and thence a mile or more to a oadside station on the line to Zagreb. Grass grew in the dockyards of the port and there were at one time only two steamers in he harbour. Just before the Corfu incident, Sig. Mussolini sent an ultimatum to Yugoslavia, and the fleet which bombarded the Greek island is said to have been originally intended or Fiume. But milder counsels prevailed, and at last a series of arrangements was concluded at Florence between the Italian and Yugoslav Govts. on Jan. 27 1924. Fiume with the larger harbour was definitely recognised as Italian; Port Baross and "the Delta" became Yugoslav, and through railway traffic, after several years' intermission, was renewed.

In 1925 the trade of the town improved; and the passage across the bridge to Sušak was no longer impeded by formalities. But he Fiuman frontier towards the north is fantastic, for a mere corridor, through which the road and railway run, connects the town with Abbazia, and is commanded by the old Roman ortress of Castua, high on the hills which dominate the Quarnero. Superficial peace reigns at Fiume; but Italy does not need three ports in the northern Adriatic and the opening (in Aug. 1925) of the last link in the Lika railway connecting Spalato with the Yugoslav hinterland is a fresh blow to Fiume, while the old Hungarian-Croatian steamship line now rechristened "Jadranska Plovidba" ("Adriatic Steamship Co.") starts from Port Baross and boycotts Italian Zara. The delimitation of the frontier by the Italo-Yugoslav commission has just been concluded. Population of the town of Fiume (1921), 45,000.

FIVES (*see* 10.450).—In Great Britain the forms most usually met with are known as Eton Fives and Rugby Fives. There are also Winchester Fives and other less-known varieties. A few rules of an older form of the game as played about 1825 still existed in 1925. Both the main games are played chiefly at the great public schools, but there are also a number of courts in various parts of the country, and the game is played in the north of England by working men. In 1924 a Fives Assn. was formed and two open competitions, one at Eton Fives and one at Rugby Fives, were instituted.

FLAG (*see* 10.454).—As one of the international attributes of a state or a sovereign, a flag has in modern times been liable to assume a new form or disappear, according to the vicissitudes of the individual political entity to which it is appurtenant. The years since 1910 witnessed greater transformations in the flags of the world than were occasioned even by the Napoleonic wars and the Congress of Vienna. As a result of the World War three imperial houses came to an end, some European states ceased o exist as such, new states emerged and old states assumed new forms. A necessary consequence of this was that historic banners such as the standards of the Hohenzollerns, the Habsburgs and the Czars ceased to exist or became obsolete, new national flags appeared and the blazonry of some of the old flags was materially changed.

Most of the states brought into existence by the Treaty of Versailles adopted flags which, though varying in design, embodied heraldic features of older banners. For example, the republic of Austria adopted the former flag of the Austro-Hungarian imperial navy without the charge, whereas the new flag of Hungary is that of the former Kingdom of Hungary. The new flag of the German Republic substitutes the national colours, black, red and gold, in place of the black, white and red which had been the distinguishing colours of the German mercantile marine. On the other hand, the former Russian national colours gave place to a new design, which departed from all traditions of heraldic law, *i.e.*, a flag bearing the letters PCΦCP (Russian Socialist Federation of Soviet Republics) imposed on a red ground. Of the new Baltic States, Finland, Latvia and Lithuania adopted flags devised in historic affinity with mediaeval banners associated with their respective localities. Estonia, however, brought into existence a new flag of no heraldic value, bearing three horizontal bars, blue, black and white, signifying respectively the blue sky, the black earth and the white shirt of the peasant. The port of Danzig adopted with modifications the flag of the city when it was an independent member of the Hanseatic League. The historic flag of Poland—before the partition—consisted of a scarlet field with a white eagle in the centre, but the flag of the new republic is of scarlet and white, the eagle being discarded. The former design is used, however, as a badge in the shape of a shield when necessary. The flag of the Kingdom of the Serbs, Croats and Slovenes is a combination of the old Serbian royal flag with that of Croatia, both these older flags having red, blue and white in differing orders, and the Montenegrin flag has disappeared.

Outside of Europe the changes have not been so marked. Egypt, as a sign of release from Turkish suzerainty, has in her flag discarded the red ground and substituted green, the design otherwise remaining intact. The Republic of China has rejected the historic dragon on a yellow ground, replacing it with a flag of five horizontal bars of different colours representing her five racial elements, *i.e.*, Mongol, Chinese, Manchu, Mahomedan and Tibetan. The flag of Morocco, as an acknowledgment of French suzerainty, now carries a tricolour canton. An entirely new flag is that of the Kingdoms of the Hejaz and 'Iraq, whilst the flags of Portugal, Panama, Turkey and Siam have undergone changes of varying importance.

See the plate of flags here given; also *Admiralty Book of Flags of All Nations*, printed for H.M. Stationery Office, London, 1916, kept up to date by the publication periodically of *Errata* officially issued.

FLAGG, ERNEST (1857–   ), American architect, was born at Brooklyn, N.Y., Feb. 6 1857. He studied at the École des Beaux-Arts, Paris, and in 1891 began to practise as an architect in New York City. He designed St. Luke's Hospital and the Singer Building, New York City, the tower of the latter (612 ft.) being the highest commercial structure in America at the time of its erection (1908). Other public buildings designed by him include the Corcoran Art Gallery, Washington, D.C., and the U.S. Naval Academy, Annapolis, Maryland. He also designed many private residences and wrote *Small Houses—Their Economic Design and Construction* (1922).

FLAMETHROWER (Ger.: *Flammenwerfer*).—This weapon was first used by the Germans in the winter of 1914–5, and with marked success in the Bois d'Avocourt (Verdun) on Feb. 26 1915. The French followed in their use. The British used them on the Somme and in the Zeebrugge attack, St. George's Day, 1918. The American Expeditionary Force did not use them at all.

Structure.—A flamethrower consists of (*a*) the container filled with some mixture of heavy and light oils, (*b*) the strong walled vessel filled with air, nitrogen, CO_2, etc., under high pressure, and (*c*) a discharge tube, with nozzle and, in most cases, an ignition device. Between (*a*) and (*b*) is a reducing valve, and between (*b*) and the nozzle a firing valve or trigger. Flamethrowers were short-range weapons, and were of two types, the heavy and the portable. The heavy type attained an extreme range of 134 yd. (British model), while with the portable British model a range of 45 yd. was attained, and maintained some 15 to 18 shots from a single filling of three gallons. The most satisfactory propellant was found to be nitrogen—either the pure product or a "deoxygenated air" produced in one field by a mobile plant.

Ignition was effected in the British types by two sparking plugs mounted in a cup containing petrol and fired by a magneto generator. The French fixed to the nozzle a tubular magazine which held a long stick of alumino-thermic composition kept up by a coiled spring and primarily ignited by a cerium steel briquet. The Germans used a double-walled cylinder, attached to the nozzle and charged with an alumino-thermic composition open to the air at the top. Inside the hollow of the cylinder and in prolongation of the bore of the nozzle tube were a piston, a spring, a striker needle, mounted on a pellet, and a cap with powder-relay. Between the cap and the needle was a fixed disk of cardboard. On release the impact of the jet on the piston compressed the spring and the striker against the cardboard disk, the needle penetrated the disk, and the spring, depressing itself, forced it on to the cap and fired the powder-relay which ignited the composition.

It is not possible to formulate any definite opinion as to the tactical value of heavy flamethrowers of the battery type. The portable type was found on occasions to be more useful than other close range auxiliaries of the infantryman.

FLATS: *see* ARCHITECTURE.

FLECKER, JAMES ELROY (1884–1915), British poet, was born at Lewisham, London, on Nov. 5 1884. He was educated at Dean Close School, Cheltenham, of which his father, W. H. Flecker, was headmaster; at Uppingham School; Trinity College, Oxford (1902–6), and Caius College, Cambridge (1908–10). He then entered the British consular service and went to Constantinople in 1910, in the same year issuing his *Thirty-six Poems*, reissued in 1911 as *Forty-two Poems*. *The Golden Journey to Samarkand*, with its notable preface summing up Flecker's Parnassian theory of poetry, appeared in 1913, after he had been compelled by consumption to leave his post at Beirut for treatment in Switzerland. He died at Davos-Platz Jan. 3 1915 and was buried at Cheltenham. Later in 1915 appeared *The Old Ships*. His spectacular Oriental drama, *Hassan*, was published in 1922 and produced in 1923, and an earlier play, *Don Juan*, appeared in 1925. His *Collected Poems* were issued in 1916. The most interesting of his few prose works was a novel, *The King of Alsander* (1914). See *Life* by Geraldine Hodgson (1925).

FLEMING, SIR SANDFORD (1827–1915), Canadian engineer and publicist (*see* 10.494), died at Halifax, N.S., July 22 1915.

FLETTNER RUDDER.—The design of this rudder constituted a radical departure from the design which for so long remained unaltered. All rudders may be said to be current-operated, but in this type the current is also used for altering the position of the rudder. The forces necessary to move the rudder of a big ship against the action of the current are very great; and a ship's steering engine requires to be of considerable horse-power, and of very robust construction. The gearing attached is heavy and more or less complicated. Such powerful steering gears should no longer be necessary. With the current-operated rudder, large ships can be steered direct by hand by the utilisation of the variations in pressure of the current on the rudder.

The principle of the invention is that of inducing negative pressure by moving the after-portion of the blade of the rudder, and of using the lateral effect thus caused by the difference of pressures on its after-part to move the rudder itself. For ships up to about 10,000 tons the Flettner rudder requires no engine to operate it, whilst in larger vessels the only additional effort necessary is that to overcome the friction in the transmission gear. The saving in effort is round about 95%. Instead of the large rudder it is only necessary to move a small one, having superficial area equal to about one-twentieth of that of the large rudder. Again, the small secondary rudder can never be placed in a position relative to the current which would cause the centre of pressure to move backwards at high speeds of ship. Manoeuvring power is greatly increased, because the rudder adjusts itself to the stream. The rudders are made either single or three-bladed, the most favoured design being the single-bladed spade type of more or less square form, which will be described in some detail.

Description of the Rudder.—The partially balanced main rudder, which is free to rotate about its axis, is steered by the secondary rudder, also balanced, hung at its after-edge. Movement by the secondary rudder is effected by the operating gear contained in a housing fixed to the main rudder.

A vertical shaft leads downwards from the operating gear through the hollow rudder stock, and terminates in a yoke which is coupled to a similar yoke on the secondary rudder by a pair of connecting rods. The operating gear is driven direct through a system of shafts and bevel wheels from alternative steering positions situated respectively on the bridge and the poop deck. In addition to the hand wheel, automatic steering is also provided by a gyroscopic compass gear, working through a ½-H.P. electric motor coupled to the steering wheel on the bridge by a chain.

The horizontal section of the rudder is of stream-line form. This shape avoids the disturbance in the even flow of water over the surface of the rudder which would otherwise be caused by the protrusion of the thick rudder-stock. It also adds to the stability of the rudder in the midship position. Moreover, this shape gives room for the protection of the connecting rods operating the secondary rudder except at the after-end, where an additional sheet-steel covering is built on as previously stated. The main rudder, which is free to rotate about its axis, is steered by the secondary rudder on its after-edge. When the latter is moved by its connecting rods, relatively to the main rudder during movement of the ship or in the slipstream of the propeller, the resulting deviation of the slipstream causes a different balance of pressures as between main and secondary rudders, *i.e.*, the main rudder being free to move, is deflected by the current through a certain angle. In going astern the balance of pressures is reversed through 180 degrees so at the moment when change of direction of the slipstream occurs the rudder automatically *turns* round through half a circle. The operating gear on the rudder-head determines the movements of the secondary rudder with relation to the steering wheel, the main rudder and the ship. (F. J. D.)

FLEXNER, SIMON (1863–), American pathologist, was born at Louisville, Ky., March 25 1863. Graduating from the University of Louisville in 1889, he pursued his studies further at Johns Hopkins University and the universities of Strasbourg, Berlin and Prague, and at the Pasteur Institute, Paris. He was associate professor and later professor of pathological anatomy at Johns Hopkins during 1889–99, becoming in the latter year professor of pathology at the University of Pennsylvania. In 1903 he was appointed director of the laboratories of the Rockefeller Institute for Medical Research, New York. Dr. Flexner became widely known in 1905 for his successful treatment of cerebrospinal fever by the use of a serum, the administration of which reduced the mortality rate from 90% in untreated cases to 46·3% in cases where the serum was used. He has published numerous monographs, including *The Pathology of Toxalbumin Intoxication* and *Mode of Infection, Means of Prevention and Specific Treatment of Epidemic Meningitis* (1917).

His brother Abraham Flexner (b. 1866) became, in 1917, secretary of the General Education Board. His views on education as set forth in *A Modern School* (1916) and *A Modern College* (1923) occasioned much discussion. He wrote also *Prostitution in Europe* (1914) and works on medical education. (*See* SPINAL MENINGITIS.)

FLINT, ROBERT (1838–1910), British divine and philosopher (*see* 10.521), died in Edinburgh Nov. 25 1910.

FLINT, Mich., U.S.A. (*see* 10.521), had a population in 1910 of 38,550, and in 1920 of 91,599, of whom 15,213 were foreign born; in 1925 the Census Bureau estimated the population at 130,316. The area in 1910 was 8,120 ac.; in 1925, 19,115 acres

e manufacture of motors and trucks, and of such contribu-
y articles as sparking plugs, carburetters, motor axles, paints
d colours, and malleable iron castings is the backbone of its
osperity. Postal receipts increased fourfold between 1910 and
24. Industrial development was paralleled in the building
homes, including noteworthy projects by some of the large
tor companies; street paving and lighting; and the construc-
n of hotels, banks, department stores, theatres and office build-
gs. A city-planning board was created in 1917. The park area
s increased to 882 ac. by 1925. Schools were built rapidly and
es acquired to provide for future expansion. In 1923 a belt-
e railway was opened.

FLORIDA (*see* 10.540).—The population of the state in 1920
s 968,470, a gain of 215,851 in the decade 1910–20. During
e five years 1920–5 the increase of population has been even
re remarkable, the state census for 1925 showing an increase
295,079, or 30.4% since 1920, the total population being given
1,263,549. In 1925 there were 21 cities with a population of
er 5,000; those then exceeding 10,000 were: Jacksonville
5,206), Tampa (94,808), Miami (69,754), St. Petersburg
6,706), Pensacola (24,958), Orlando (22,273), West Palm
ach (19,122), Key West (13,533) and St. Augustine (10,190).
e rapid development of Florida cities and towns is giving
e state a larger proportion of urban population than any other
uthern state. However, Florida's population is still pre-
minantly rural. In 1920 only 36.7% of the entire population
s urban (living in cities or towns of over 2,500). During the
nter months the population is largely augmented by thou-
nds of tourists and winter residents, quite a number of whom
come permanent residents or invest in Florida property.
r many years the coast resorts were the chief objectives, but
any of the inland towns and cities are now attracting out-of-
ate visitors. Far larger numbers of pleasure seekers have
sited Florida in the two years 1924–5 than ever before, and
is movement is certain to grow.

Industries and Commerce.—Florida's most extensive industry
agriculture. According to figures of the Florida Experiment
ation there were approximately 5,940,000 ac. of land in farms
1925, not including open or fenced range lands. Of this,
400,000 ac. were in crops, and 618,000 ac. of crop lands were
le; 275,000 ac. were in fruit; 1,500,000 ac. were in pasture; and
147,000 ac. in woodland. On approximately one-third of the
ltivated acreage crops were produced by intertillage (the
owing of two or more crops on the same land at one time) and
succession planting (where two or more crops follow each other
the same land in one year). The number of farms in Florida,
as 50,016 in 1910, 54,005 in 1920 and 59,817 in 1925. Fruit is
lorida's most important crop. The citrus industry has pros-
ered despite the fact that some of the groves in the more north-
n part of the state have suffered from heavy frosts in severe
inters. In 1920 the production of oranges was 8,500,000 boxes,
d of grape fruit 5,000,000 boxes. In 1925 the production was
,700,000 boxes of oranges and 6,300,000 boxes of grape fruit.
the sub-tropical part of the state pineapples, lemons, guavas,
d avacadoes are grown profitably on a commercial scale.
ther fruits produced are peaches, pears, bananas, grapes, figs
d limes. The more important crops with their 1925 acreage
elds and values, are tabulated in the next column.

There was a falling off in the production of cotton during the
ecade 1910–20; however, a good cotton season during 1925,
d the use of short staple cotton which is more resistant to the
oll weevil, more than doubled the state's production over the
op of 1920. The tobacco-growing section of western Florida
oduces profitably a shaded leaf, grown from Cuban and Suma-
an seed, which is in great demand in cigar manufacturing. The
ecan industry is comparatively new, most of the commercial
oves having been planted since 1905. It is believed that in the
rthern part of the state the pecan crop may soon compete
osely with the citrus crop of the southern part. The production
early vegetables for the northern markets is developing
pidly, and the Florida producer can put vegetables on the
arkets earlier than any of his competitors. The chief obstacles are costly rates and inadequate railway freight and express service. Much attention was formerly paid to stock-raising, but with the taking up and development of much of what was formerly open-range land, the figures for 1925 show a decided shrinkage in the production of livestock since 1920. In 1925 there were 662,000 cattle, including milch cows, valued at $13,240,000; 61,000 sheep, valued at $200,000; 506,000 swine, valued at $3,289,000; 31,000 horses, valued at $3,000,000 and 43,000 mules, valued at $5,934,000. These livestock statistics include only farm animals.

	Acres	Production	Value
Staple Crops:			
Corn	580,000	8,700,000 bu.	$ 8,700,000
Cotton	106,000	40,000 bales	3,541,000
Hay	82,000	57,000 tons	1,296,000
Sugar-cane	9,000	2,100,000 gal.	2,205,000
Sweet Potatoes	29,000	2,465,000 bu.	4,060,000
Tobacco	7,000	5,460,000 lb.	1,693,000
Truck Crops:			
Irish Potatoes	23,000	2,599,000 bu.	6,757,000
Snap Beans	20,530	1,663,000 hmprs.	2,494,000
Celery	4,320	2,000,000 crates	3,700,000
Cucumbers	10,830	1,256,000 hmprs.	1,520,000
Lettuce	3,400	765,000 crates	1,170,000
Peppers	3,400	1,115,000 bu.	2,787,000
Strawberries	3,170	6,023,000 qt.	1,807,000
Tomatoes	33,470	2,811,000 bu.	6,325,000
Watermelons	20,910	7,841 cars	2,352,000
Fruit and Nuts:			
Grape fruit	..	6,300,000 crates	11,340,000
Oranges	..	10,700,000 crates	26,750,000
Peaches	..	115,000 bu.	190,000
Pecans	..	1,340,000 lb.	348,000

In 1925 Florida produced mineral products to the value of $10,908,000, the more important of which were phosphates, lime, limestone, brick, tile, kaolin and fuller's earth, of which latter Florida produces about three-fourths of the entire U.S. output. In 1924 the production of phosphate was: land pebble, 2,348,137 long tons, valued at $7,987,752; and hard rock, 199,516 long tons, valued at $1,071,675. Florida's lumber production, due to exploitation, shows a decline since 1916, when an output of 1,425,000,000 ft. was reached; the 1924 production, mainly cypress and yellow pine, was 980,014,000 feet. Considerable hard wood (chiefly hickory) is produced. Naval stores are produced from the pine forests, where the sap of the trees is collected and distilled, yielding turpentine and resin. In 1923 Florida produced 9,747,000 gal. of turpentine valued at $10,000,000 and 660,000 bbl. of resin valued at $4,000,000.

In 1924 Florida manufactured 546,799,000 cigars, valued at $35,000,000; and 2,767,000 cigarettes, valued at $55,000. A rapidly developing manufacture is that of commercial fertilisers, large amounts of phosphate mined in the state being used for this purpose. Some index of Florida's recent business growth can be gained from the following banking statistics: deposits in National banks in Jan. 1920, $187,286,267; in Jan. 1925, $375,042,947; in state banks and trust companies in Jan. 1920, $197,809,947; in Jan. 1925, $287,636,588.

History.—The outbreak of the World War in 1914 interrupted two of Florida's more important exports to Europe, *i.e.*, naval stores and phosphates, thus creating a temporary business depression. In the naval-stores industry the recovery was comparatively rapid, owing to the high prices of and increased domestic demand for the products, after the first few months of the War. The phosphate industry was more seriously affected, as Germany had been a large purchaser. Many phosphate mines closed down, to resume operations only after the signing of the Armistice.

The political history of the state during the years 1910–25 was uneventful. The question of Prohibition played a large part in state politics until the ratification of the Eighteenth Federal (Prohibition) Amendment by the Florida Legislature

Dec. 14 1918. Since 1876 Florida has been uniformly Democratic and, except in 1916, when a contested primary election in the Democratic party resulted in the nomination of Sidney J. Catts as a prohibitionist and in his election as governor, all of the state's executives have been Democrats. The governors since 1910 were: Albert W. Gilchrist (1909–13); Park Trammell (1913–7); Sidney J. Catts (1917–21); Cary A. Hardee (1921–5), and John W. Martin, (1925–). In 1924 Florida adopted an amendment to the state constitution forbidding the Legislature to levy an income or inheritance tax. (J. M. L.)

FLOUR MILLING (*see* 10.548).—Profound changes have occurred during the period covered by our work (1910–26) in the geographical distribution of the flour-milling industry. The great increase that took place in the production of wheat in the U.S.A., Canada, Australia and Argentina, the relatively low cost of production in those countries, and the cheapness of transportation, together with the universal drift of the population from the rural to the urban districts, brought about the building of large flour-mills at the principal ports of Great Britain and other countries, and the gradual extinction of many small rural mills.

American Milling.—In the three Canadian provinces of Manitoba, Saskatchewan and Alberta, alone, in less than a quarter of a century the quantity of wheat grown was increased from 23,000,000 to 446,000,000 bu., and the export flour trade rose from 306,339 bar. (196 lb.) in the season 1871 to over 11,000,000 barrels in the season 1924–5. As wheat production increased, so also did the number of flour-mills, which were built regardless of domestic requirements in the United States, Canada and Australia. This was based on the assumption that flour could be most economically milled in the countries in which the wheat was grown.

European Milling.—In Europe, Germany and France, in particular, aimed at growing sufficient cereals for their own use, and heavy duties were levied on imported grain and flour to aid the process; in these cases, also, there was an increase in the capacity of the flour-mills to correspond with requirements. Great Britain and a few other countries placed their reliance on imported wheat, which was more suitable for breadmaking purposes than the native varieties; but here, again, they increased their capacity for the manufacture of flour, notwithstanding the same tendency in the wheat growing countries.

Active Competition.—Thus a situation arose in which the capacity of the mills in several countries exceeded the requirements of the population. Millers began to seek hungrily for trade farther afield. American, Canadian and Australian mills made unremitting efforts to supply Europe and the Far East with flour, entering alike overloaded and deficient countries. This current of trade in Europe was met by other currents flowing from England, Germany, France and other countries, the result being a swirl of competition that, however beneficial to the consuming public, engendered a certain amount of anxiety in the trade.

In the years which immediately preceded the War, a world-wide scramble for trade had begun. From 1914 to 1918, however, the feeding of the armies and the civil population was under the control of the respective governments concerned, and with the redistribution of supplies all the mills were kept going at full speed. In Great Britain additions were made to some of the plants, the aggregate peacetime capacity of which already exceeded requirements. The millers of England and Wales found themselves at the end of the War in possession of a potential manufacturing capacity of 40,000,000 sacks (280 lb.) of flour per annum, or an excess of 10,000,000 sacks over requirements. Scotland and Ireland were and had remained under-milled, but the English mills can supply their deficiency and still have several million sacks to spare.

After the state had liberated the industry from control in March 1921, British millers were compelled more than once by stress of circumstances to impose voluntary control upon their business, notably in 1921, when there was a record slump in the price of wheat, values declining by more than 40s. a quarter in a brief period.

For several years the situation was relieved by the demand for breadstuffs on the European continent. Shattered as these countries were by the four years of war, they could not, as formerly grow or grind sufficient wheat for themselves, and one after another they relaxed or abolished their tariffs on imported cereal and flour. During this period the exports of flour from Great Britain rose to the unprecedented height of over 3,000,000 sacks.

But so soon as the grain-growers on the Continent had succeeded in increasing their production more nearly to correspond with national requirements, both they and the flour millers exerted themselves to secure the re-imposition of tariffs. In Germany there was resistance from the urban element, but in Oct. 1925 grain and flour imported to Germany were again subject to customs duties. In France, millers were compelled by law to mix rice and other cheaper flour with their wheaten flour, and these regulations were finally removed in 1925.

The growing Chinese and Japanese demand for wheaten products was met partly by American and Canadian mills. But in these Far East as in other countries at present under-milled, new flour-mills were erected to meet the increasing demands, so that further readjustments in distribution appear to be inevitable. In the U.S.A., Canada, Australia and England, the mills were unable to work at their full capacity. In New South Wales (Australia) the quantity of flour required by the population of 2,250,000 people was 225,000 tons per annum, and the mills of this State could produce exactly double that quantity. The U.S.A. and Canadian mills shared the same difficulties. In Minneapolis, the largest flour-milling centre in the world, the mills were not able to work to anything like their full capacity for several years. In Great Britain, whilst the excess capacity amounted to 10,000,000 sacks per annum, on an average 4,000,000 sacks of flour came into this country from the U.S.A., Canada, Australia and elsewhere, so that the problem in this case is intensified by imports.

The tendency generally is towards large scale production. It is estimated that 50% of the flour required by the population of Great Britain is milled at the principal ports, approximately 17% at mills in large inland centres of population, and 33% at mills in country areas. The flour-milling industry has encountered inexorable economic laws, from the authority of which there is no escape, and, unless there is a voluntary arrangement to produce flour to conform with requirements, the fittest only will survive the stress of competition.

FLYING, COMMERCIAL (*see* also Aerial Navigation; Aeronautics; Aeroplane; Airship; etc.).—Commercial aviation may be said to embrace all forms of flying other than that carried out by the fighting forces and may be divided into the following categories: (1) Air transport; (2) Aerial survey; (3) General flying; (4) Flying schools; (5) Air racing.

I. AIR TRANSPORT

This section is confined to that particular branch of aeronautical activity described as air transport.

Air transport is an entirely modern innovation. Balloons were employed for the carriage of messages from Paris during the siege of 1870, a war measure for evading the besieging army which, in other circumstances, could not have claimed to be a practical method of carrying mails. Between 1909 and 1914 various demonstrations were made to prove the suitability of the aeroplane as a rapid conveyance for mail matter, and a considerable number of journeys by air were accomplished by private individuals; but none of these enterprises, though interesting and daring, could fairly be described as the real beginning of air transport.

That air transport would become a practical proposition was, however, recognised, and in 1910 a conference was held in Paris at which an International Convention in regard to aerial navigation was drafted. The credit for the first genuine commercial air service lies with Germany; from March 1912 until Nov. 1913, the rigid airships "Victoria Luise," "Hansa" and "Sachsen" plied regularly between Berlin and Friedrichs-

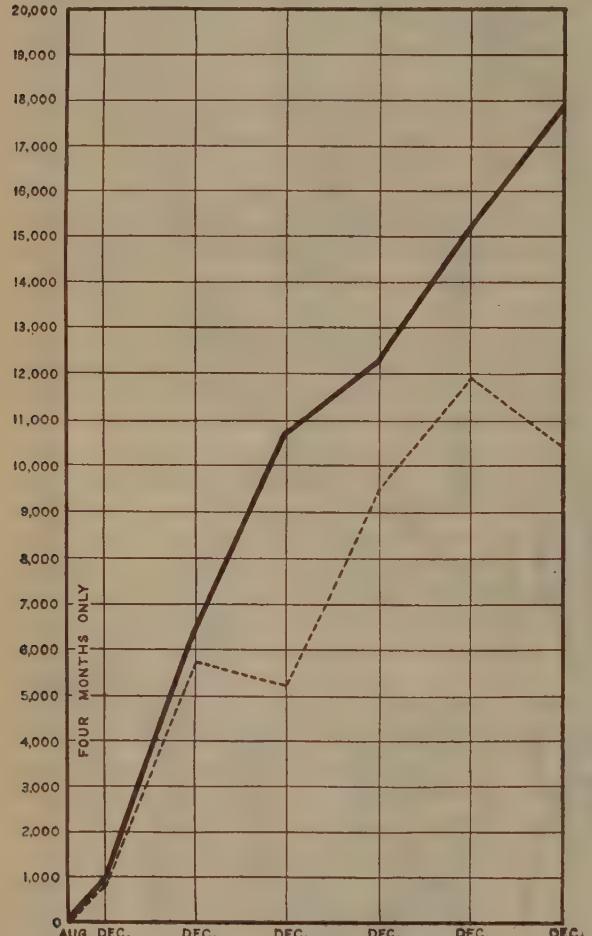
hafen, and in 881 flights, totalling 65,500 m., carried 19,105 passengers without injury and in considerable comfort.

HISTORY IN GREAT BRITAIN

The British Government can claim to be the first government to study the possibilities of air transport seriously. On May 22 1917 a Civil Aerial Transport Committee was appointed to advise the Air Board on the steps that should be taken for the development and regulation of aviation for civil and commercial purposes. This committee examined the possibilities of air transport from every point of view, and eventually submitted a report to the Air Council on May 11 1918.[1]



Graph showing annual air traffic on London-Continent routes. Total passengers (continuous line), and passengers carried by British aircraft (broken line).

Aeroplanes and Seaplanes.—At the conclusion of the War, the whole world began to turn its attention to the possibilities of aviation as a commercial activity. Five years of forced technical progress and intensive production had left a great heritage in aerial resources; practically every combatant nation possessed large numbers of pilots and mechanics and vast stores of surplus war aircraft. Military aircraft had been used for purely communication purposes with complete success; and the operations of war had proved clearly that flying under peace conditions should be both safe and comfortable. It was obvious that, if air transport was to accomplish even a small proportion of that which enthusiasts claimed for it, international regulations must be put into force as soon as possible, and the necessary steps were taken at the Peace Conference in Paris during 1919.

International Convention.—The Treaty of Versailles brought into being an International Convention for the Regulation o Aerial Navigation in which all the Allies participated; unde the terms of this convention a permanent commission for Ai Navigation was to be set up and placed under the direction o the League of Nations. In Great Britain, except for a brie period during Easter Week 1919, post-War civil aviation did no commence officially until May 1 1919. On Aug. 26 1919 international civil flying from Great Britain was first started unde temporary air navigation regulations.

The International Air Convention by June 1922 had been ratified by a sufficient number of signatory states to make th introduction of its regulations practicable. It was brought int force in Great Britain by the Air Navigation Order dated June 2 1922. Accordingly the first meeting of the International Commission for Air Navigation was opened in Paris on July 11 1922

The Start of the Service.—Air transport began its career unde somewhat evil auspices. On the one hand, a large body o enthusiasts claimed the certainty of immediate commercia success, and consequent financial profits; on the other, conservative scepticism pooh-poohed the idea that aeroplane could ever be a safe and economical means of transport, an cynically supported financial subsidies to the new industry England led the way in accomplishment. On Aug. 25 1919 th Aircraft Transport and Travel Co. despatched the first aircraf to fly on a regular commercial service to Paris and on Nov. 1 1919 an aeroplane belonging to the same company carried th first regularly established air mail to the same destination. Th British Handley-Page Air Transport Co. and the French Messageries Aériennes were quick to follow and by Jan. 1 1920 there were three British and two French companies operating on regular time-table across the Channel. These operations were nearly all carried out by military aircraft, or by military aircraf modified to carry passengers in some degree of comfort.

Need for State Aid.—From the first it was obvious that suc aircraft could not pay their way. It was, therefore, clear that air transport could not at once become self-supporting anc would need some financial assistance from the state, until experience was gained and aircraft specially designed for commercia purposes were produced with the aid of that experience.

The French Government had already realised the vast possibilities of air transport and a costly and ambitious polic of financial assistance was inaugurated in 1919 and has been continued until the present day. To some extent this polic was inspired by its potential political and military influence o the countries flown over, but its ultimate object was to attai rapid communication between Paris and the French Colonie in Africa and Asia.

In England, on the other hand, there was not sufficient mone allotted for even a very low standard of aerial defence, and ai transport was therefore relegated to the background as a enterprise which the nation could not afford. In fact, th British Empire had as much to gain from its developmen as any other country in the world. Consequently the pioneers, and with them the public who had supported thei new enterprises financially, walked towards inevitable ruin The general financial crisis of the autumn of 1920 brought matters to a head, and the Aircraft Transport and Travel Compan went into liquidation in Dec., whilst in Feb. 1921 the Handley Page Transport Company suspended operations, leaving th French in unchallenged occupation of the cross-Channel routes This disaster brought about a parliamentary and press agitatio which galvanised the Government into facing facts and doin something; and from March 1921 the cross-Channel servic have been subsidised in varying degrees.

Governmental Committees.—The following are the variou committees and boards which were set up by the British Government from 1917 to 1923 to consider the possibilities of ai transport and to make recommendations as to how it could bes be supported and developed:—

ivil Air Transport Subsidies Committee ("Hambling Committee")	Jan. 2 1923	Feb. 15 1923	"Report on Government Financial Assistance to Civil Air Transport Companies," dated Feb. 15 1923. (Cd. 1811, price 6d.)
ir Mails Committee	June 1923		"Interim Report of the Air Mails Committee," dated Jan. 19 1924. (Cd. 2038, price 6d.)

From March 1921 until March 31 1922 two British com- nies continued limited operations between London and Paris der a system of government financial support which guaran- d them a 10% profit on the receipts obtained for traffic ried. Whilst this temporary and admittedly extravagant asure was in force, the Londonderry Committee put forward a w scheme which was accepted by the Government, and was in eration from April to Sept. 1922.

overnment Aid: the Londonderry Scheme.—This new scheme nprised the provision of half the fleet of each company by the vernment on a hire purchase system, and a subsidy based rtly on the load carried and partly on the gross earnings of the mpanies. Three companies, the Handley-Page Air Transport, Instone Air Line, and Daimler Airways, operated to Paris, d one company, the Instone Air Line, flew to Brussels. It s very soon found that the hire purchase scheme was im- acticable. Moreover, the traffic available between London and ris was not sufficient for five competing companies (three itish and two French), and it was obviously unsound that itish companies should be subsidised to compete against one other.

Modified Scheme.—On Oct. 1 1922, therefore, this scheme was odified on the basis of avoiding competition between British mpanies and extending British air transport into Europe as as possible with the money available. On this system the proved services in operation from this date until March 31 1924 given in table in next column.

Meanwhile, owing to the various difficulties which had arisen d the apparent wastefulness of maintaining four separate ganisations for a comparatively small volume of traffic, the mbling Committee was assembled in Jan. 1923. This mmittee definitely recommended the amalgamation of the r existing companies into a single national company with eat freedom of action. They indicated that the company must provided with a substantial capital, and be guaranteed a nopoly of subsidy for a term of years.

"*Imperial Airways" Founded.*—As a result, in March 1924, a tional company, Imperial Airways, Ltd., was brought into ing with a guarantee of a total subsidy of £1,000,000 spread er a period of 10 years, for regular flying carried out within Europe, the contract with the Government permitting liberty of action as to the services actually operated. The frequent modifications of system and changes of policy had naturally militated against serious progress, and when at length this new organisation came into being it encountered many setbacks and difficulties in its first 18 months of operation, but it now promises to bring air transport on to a definitely self-supporting basis before any other similar enterprise receiving a subsidy from its Government.

Firm	Service	Annual Minimum Services in Each Direction	Annual Minimum Total Mileage	Annual Maximum Subsidy
Handley-Page Transport, Ltd.	London, Paris	300	....	£ 15,000
Instone Air Line, Ltd.	London, Brussels, Cologne	300	....	25,000
Daimler Hire, Ltd.	Manchester, London, Amsterdam, Hamburg, Berlin	....	253,846	55,000
British Marine Air Navigation Co., Ltd.	Southampton, Cherbourg, Havre, and Channel Islands	....	60,000	10,000

History in Other Countries

In other parts of the British Empire, air transport generally made little progress, with the exception of Australia, where a good deal has been done.

Australian Development.—Australia has subsidised three important air lines—Western Australian Airways, Ltd., operating once a week from Perth to Derby (1,442 m.); Queensland and

Northern Territory Aerial Services, Ltd., Cloncurry to Camooweal; and the Larkin Aircraft Supply Co., Ltd., Adelaide to Cootamundra, with two branches, one from Mildura to Broken Hill and one from Hay to Melbourne.

German Activity.—Germany had entered the lists as soon as the conditions of peace permitted her and, to encourage private enterprise, offered a simple subsidy on a kilometric basis. As a result there are to-day two substantial German air transport companies—the Deutscher Aero Lloyd A.G. and the Junkers Luftverkehr A.G. in operation. The former is supported by some of the leading banks and shipping companies and utilises various types of aircraft. The latter is the property of the great Junkers engineering firm and is equipped entirely with all-metal Junkers aircraft.

The Junkers Co. has created a world-wide reputation by means of a comprehensive scheme of standardisation in manufacture. Endeavours have been made to establish subsidiary companies in various countries in Europe and in other parts of the world, over which control has been obtained by the provision of the initial fleet in exchange for shares. A scheme for the economical overhaul of all these aircraft at a flat rate at the Junkers works has also been evolved. Junkers companies exist in Switzerland, Denmark, Sweden, Austria, Hungary, Finland, Estonia, Latvia, Russia, Trans-Caucasia, Colombia and Argentina, in addition to which Junkers have created numerous subsidiary companies within Germany itself. This bold scheme is almost identical with that on which the British Air Transport and Travel Co. was embarking when it came to an untimely end through lack of Government support in 1920. Its progress has been remarkable, but its eventual success must depend on the power of the Junkers Co. to bear the heavy capital charges involved in the provision and maintenance of these fleets until such time as the subsidiary companies' shares attain a serious financial value.

French Progress.—France meanwhile has put her house in order and now has three main companies operating in different zones:—

Air Union, Paris–London.
Compagnie Internationale de Navigation Aérienne (late Franco-Roumaine), Paris–Constantinople.
Compagnie Générale d'Entreprises Aéronautiques (late Latécoère), Toulouse–Dakar.

All these companies are generously subsidised by the French Govt. and in addition Czechoslovakia, Yugoslavia and Rumania give financial support to the C.I.D.N.A., whilst the C.G.E.A. is assisted by French Morocco.

American Policy.—America did not participate in the International Commission for Air Navigation and has adopted an entirely different line of policy from the European nations. S refused all assistance to private enterprise and even neglect to bring any form of air navigation regulations into force. the same time, she started and operated a most efficient b somewhat extravagant air mail service between New York a San Francisco. This service was equipped with old war aircra of British design and Liberty engines, and was administered the Post Office. Its operations were remarkable for their ef ciency and regularity, and in 1924 the first regular night flyi service in the world was carried out on the central sectio between Chicago and Cheyenne.

In 1925 America opened negotiations with a view to handi over the mail route to private enterprise, and is endeavouring persuade private operating companies to undertake mail servic on the other routes on a letter surcharge basis. Air Navigati Regulations have also been finally approved and prepared f promulgation. During the above period other nations we coming into the field of air transport.

Air Transportation in other Countries.—The Dutch created subsidised company called the Koninklijke Luchtvaart Maa schappij voor Nederland en Kolonien towards the end of 19 which has operated to London and Paris with great efficienc equipped with Fokker aircraft and British engines. Belgium h organised a national company called the Société Anonym Belge pour l'Exploitation de la Navigation Aérienne. Europe it operates during the summer between Brussels a Basel, and in Africa it has established a very successful service the Belgian Congo from near Leopoldville to Luebo and Eli abethville. Spain, Sweden, Poland, Switzerland, Denmar Austria, Hungary, Finland, Estonia, Latvia, Norway a Russia have all established air transport companies and p them into operation. Czechoslovakia, Italy and Yugoslav have companies which in 1926 were about to commence operatio on a fairly extensive scale.

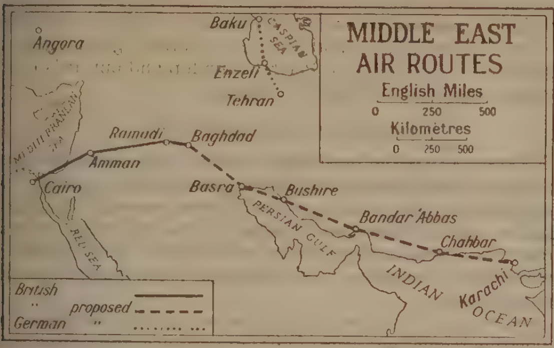
Air Service to India.—The British Govt. is at prese establishing an air service operating aeroplanes between Cai and Karachi. The section between Cairo and Baghdad has alrea been flown once a fortnight by military aircraft belonging to t Royal Air Force for the carriage of mails and official passenge t is now proposed to hand this section over to Imperial Airways nd to extend it to Karachi via Basra and the coast of the ersian Gulf.

The preliminary reconnaissance of the route has been carried ut and the necessary arrangements made with the governments f Egypt, Palestine, 'Iraq, Persia and India. A contract involving he payment of a subsidy for five years has been signed, a lump um being given for each completed stage between Cairo and Basra and between Basra and Karachi. It is probable that this ervice will commence operations in Nov. 1926 with aircraft f the latest type equipped with three air-cooled engines.



Construction, Cost and Service

During the years that elapsed between 1918–26 many lessons were learned and certain facts established.

Safety.—First, it has been proved that air transport when roperly administered and operated is a safe means of travel.

In the British air service between May 1919 and March 1925 here were six fatal accidents, only four of which involved the eath of passengers, for 3,698,000 m. flown, the equivalent of 48 times round the equator. In Australia there was only one atal accident[1] and 570,000 m. were flown between the starting of perations in Dec. 1921 and the end of 1924.

Reliability.—A very high standard of efficiency has been eached and a standard of as much as 97% and 98% regularity n flying to a published time-table is claimed for certain air lines perating during summer weather. Three quarters of the ailures to maintain perfect regularity are due to weather and ailure of power-plant, 66% being due to weather and 34% to mechanical defects throughout the year. This high standard of regularity and safety in British air transport was obtained very largely through the skill and determination of the pilots; and throughout Europe it may be said that good piloting has usually been the greatest factor in any success obtained. Thus it can be claimed that by the end of 1925 much valuable experience had been gained, and a very creditable standard of security and regularity had been attained; this standard was certainly as high as could be expected with the equipment available.

Economy.—On the other hand, although some progress was made during these six years towards economical operation, air transport is still far from arriving at a point at which it can be counted on to operate commercially without artificial financial assistance.

Cost of Operating.—There are two main reasons for the high cost of air transport as compared to other means of locomotion. First, an aeroplane expends a considerable proportion of its horse-power in climbing into the air and on maintaining itself at a safe height without regard to forward speed; in all other forms of transport the vehicle can remain at a fixed level on or in its particular element without expenditure of power. Secondly, in order to obtain as great a disposable load as possible for any given horse-power, the structure of both engine and aircraft must be extremely light. Consequently the air transport vehicle is costly to construct, and through its comparative fragility involves a high rate of maintenance. The cost of operation per hour depends to a great extent on the horse-power employed; thus every endeavour is being made, not only to increase the total weight per horse-power carried, but also to ensure that the greatest possible proportion of this total load is devoted to disposable load at the expense of structural weight. Progress in this direction, however, has received certain setbacks by the proved necessity of carrying extra instruments, safety devices, heating and ventilating apparatus, etc.

As indicated above, a considerable measure of reliability and safety has already been attained, and steady progress is being made towards increasing this standard to a basis of equality with other forms of transport.[2] The problem of reducing the operating cost to really commercial rates is more difficult, and represents the most important question before the designers of commercial aircraft to-day. Progress is being made on broadly two main lines, the reduction of maintenance costs, and the increase of paying load per horse-power. Air-cooled engines are just coming into use; all-metal construction is beginning to replace wood and fabric; and a robust engine burning crude oil is promised in the near future. Each and all these innovations will appreciably reduce the cost of operation.

Design, Cost and Carrying Capacity.—England leads the way in the development of air-cooled engines and Germany in metal construction. On the other line, various mechanical developments are being applied to increase the disposable load without adding to the weight and size of the aircraft itself. The greatest load which an aircraft can carry is that with which it can take off and land safely. Once at a safe height in the air, the normal aircraft has plenty of lifting power in hand. The planes are being fitted with adjustable slots and flaps which permit of a greater load being lifted from the ground in safety, and which lower the landing speed of heavily loaded aircraft which otherwise might be dangerous. Considerable increase in horse-power is being obtained without serious additional weight by means of various systems of supercharging and "boosting" aircraft engines. Variable-pitch propellers are just emerging from the experimental stage, by the use of which much more efficient application of the horse-power available will be attained. The newly invented de la Cierva autogiro promises to be a very valuable factor in progress towards carrying greater loads.

Data regarding costs per ton-mile are not at present available from foreign nations, and in England, owing to constant changes of policy and administration, it is difficult to obtain reliable figures. It is claimed, however, that with existing aircraft it is possible to operate at a speed of 85 m. an hour at 5s. a ton-mile, of which 3s. a ton-mile represent operating costs and 2s. overhead charges, including maintenance and depreciation.

By means of various steps in technical progress, including those mentioned above, it should be possible to reduce these costs to less than 1s. a ton-mile for operating costs, and as safety and reliability are enhanced, traffic will increase and overhead charges will drop to a rate which may also be estimated at 1s. a ton-mile. With a total cost of 2s. a ton-mile, air transport should be able to pay its way on many lines of communication between the great centres of the world's commercial activity.

Summary of Conclusions.—To sum up it may be stated that by the end of 1925 air transport operated by means of aeroplanes and seaplanes has proved to be safe, and under European summer conditions very reliable. This new means of communication cannot function, however, without artificial financial assistance. Great progress is being made towards evolving aircraft which will be able to earn their costs of operation. As the receipts for traffic approximate more and more to the expense of flying, air transport activities will rapidly increase; and when air transport with aeroplanes and seaplanes eventually reaches a paying basis, it must inevitably become one of the most important means of communication between the various parts of the world.

Airships.—Since the early Zeppelin enterprise in Germany during 1912 and 1913, no regular commercial airship service has been put into operation, with the exception of the experimental service with the "Bodensee" run by the Zeppelin Company from Aug. to Dec. 1919. Germany, the chief user and most experienced designer of rigid airships, lost practically the whole of her airship organisation under the terms of the Treaty of Versailles; the ships which were handed over by her to the Allies were not suited for commercial work; England and France had not the necessary faith in the future of airships to justify the expenditure necessary for their further development; and it was only in America that progress was continued. This general stagnation was further justified in the minds of unbelievers by the disasters which overtook the British ship R38 in Aug. 1921 and the French "Dixmude" in Dec. 1923. The finest performance by an airship since 1918 was the flight of the British-built ship R34 from England to New York and back during the summer of 1919. (Left England July 2 1919, arrived America July 6 1919: 108 hours. Left America July 10 1919, arrived England July 13 1919: 75 hours).

[2] Lee, "The Lessons of Six Years' Experience in Air Transport" in *Jour. of the Royal Aeronautical Society,* No. 179, vol. 29 (Nov. 1925).

Airship Service.—Although America led the way by the construction of the "Shenandoah" and the demand that the ZR3, later the "Los Angeles," should be built in Germany as part of her war reparation, it was England that made the first serious step towards establishing a genuine commercial airship service.

This policy was initiated during 1923. After much discussion, towards the end of 1924 the construction of two large airships was put in hand, one to be built by Government and the other by private enterprise. In the design of these airships the orthodox type of Zeppelin girder has been departed from, and many improvements, the result of practical scientific research, will be incorporated in the structure. In connection with this scheme the existing airship station at Cardington near Bedford is being enlarged and a terminal airship station is being erected in India at Karachi. A temporary refuelling station has been established at Ismailia on the Suez Canal. The contract for the privately built ship includes a satisfactory flight to India along this route.

The following data are given to indicate the progress in rigid airship construction attained during the last few years:—

	Description	Horse-power	Speed m.p.h.	Extreme radius at this speed (without paying load)	Disposable load
				Miles	Tons
R34	Old British ship built in England during the War . .	1,250	Max. 63·5 = Cruising 45 =	3,286 4,905	26·55
ZR3	Zeppelin ship built in Germany for U.S.A. . . .	2,000	Max. 79 = Cruising 68 =	5,490 7,937	46
R101	Ship under construction by British Govt.	3,500	Max. 78 = Cruising 65 =	7,900 13,000	85

Use of Helium.—America has introduced helium gas to replace hydrogen as a lifting agent. Helium (*q.v.*) has the advantage over hydrogen that it is totally non-inflammable, but its production is extremely costly, and its lifting power 15% less than that of hydrogen, which facts will prove a very serious handicap in the commercial development of the airship in America, if this policy is continued. In England, it is the intention to fit crude oil engines to the big ships and so eliminate the element of danger incurred by carrying petrol. No dependable data exist from which the cost of operating an airship can be estimated, but there is little doubt that if the constructional and handling difficulties which have been connected with airships up to date can be overcome, the operating cost per ton-mile will be very much less than in heavier-than-air craft, although the initial capital cost involved is very much greater. The possibilities of the airship as a means of communication over long distances and across the great oceans are therefore enormous.

Co-operation with Aeroplanes.—It seems certain that in the future airships and aeroplanes will work in co-operation. As existing schemes develop, traffic for 'Iraq will reach Egypt by airship and proceed thence by aeroplane to Baghdad; for India, to Colombo by airship and thence to various great cities by aeroplane; for Australia, to Perth by airship and onwards to the northern and eastern cities by aeroplane.

INTERNATIONAL AGREEMENTS

Air transport is the most truly international of the transport industries; international laws and regulations are necessary for the operation of ships at sea and of trains across great continents. But the scope of these two activities is strictly limited, whereas aircraft can penetrate anywhere and fly over the territories of several different nations in a journey of a few hours' duration (*see* AERIAL LAW).

It has always been evident, therefore, that international air navigation regulations were of vital importance, and during 1922, on ratification of the International Air Convention, to which reference has already been made, the International Commission for Air Navigation (known as the I.C.A.N. in England and as the C.I.N.A. on the continent of Europe) came into being. The following states are parties to the convention and send representatives to this Commission:—

1. Belgium.
2. Great Britain and Northern Ireland.
3. Canada.
4. Australia.
5. Union of South Africa.
6. New Zealand.
7. Irish Free State.
8. India.
9. Bulgaria.
10. Chile.
11. France.
12. Greece.
13. Italy.
14. Japan.
15. Persia.
16. Poland.
17. Portugal.
18. Rumania.
19. Kingdom of the Serbs, Croats and Slovenes.
20. Siam.
21. Czechoslovakia.
22. Uruguay.

The general principles laid down by the Convention are as follows:—

1. Innocent passage of commercial aircraft of the members over the territories of all.
2. Designation of customs aerodromes at suitable points at which aircraft must land.
3. Issue of licences to all members of the crew and airworthy certificates to all aircraft engaged in international commerce. The forms of these licences and certificates and the qualifications and tests to be demanded have been agreed by the Commission.
4. The establishment of a wireless and meteorological organisation and a lighting system along air routes authorised by the nation over whose territory they lie.

The full Commission now meets twice every year, the place of meeting being decided on the invitation of one of the Governments represented. Meetings have taken place, so far, during 1922 in Paris and London; during 1923 in Brussels, London and Rome; during 1924 two meetings in Paris, and during 1925 in London and Brussels. The Commission has appointed standing subcommissions for the detailed study of operational, technical, medical and legal problems, and these meet as convenient at various dates between the meetings of the full Commission. Most European nations who are not members of the International Commission have drawn up regulations of their own, approximating to those of the International Commission, and many of them have entered into agreements of various classes and duration with one another and with members of the International Commission in order to facilitate the operation of international air transport.

Since its creation the Commission has taken steps to modify two articles of the Convention which were unacceptable to certain ex-neutral and ex-enemy countries. These modifications will come into force in the near future on the completion of ratification, when it is likely that several other European nations will join the Convention. As already stated, America, hough a signatory to the Convention originally, has never posited her ratification and is considering Federal legislation the administration of inter-state air transport.

Each country through its national legislature gives effect to International Air Convention and to the decisions of the ternational Commission. In Great Britain this is done by the Navigation Act, 1920, and by the air navigation orders and navigation directions issued by the authorities from time to ne thereunder.

II. AERIAL SURVEYS

Aerial survey came into existence during the World War. ie necessity of photographing trench-lines and hostile positions came more and more vital as operations progressed, and by 18, military aerial photography had reached a high pitch efficiency. It was only in a few cases, however, that it was cessary to employ aerial photography as a means of measuring stances on the ground; as a rule, comparatively accurate maps re available, and the photographs were required for filling in tails of natural features, buildings, roads, etc., and for dis- osing the dispositions of the enemy.

At the end of the War, it was clear that aerial photography ust provide a very valuable aid to ordinary survey, and from at date onwards aerial survey has been very successfully veloped in various parts of the world.

Aerial Survey Problems.—The greatest problems of aerial rvey activities are:—

1. To correct for the errors which must obviously result from otographing tracts of country in which considerably different ight levels exist.
2. To ensure that photographs are taken with the camera axis as ar as possible vertical and to correct the results of deviations from is ideal.
3. To fly straight and level and at a constant height so as to ensure gular overlap of all negatives obtained, and as near as may be a nstant scale.
4. To reduce operation costs to a standard at which aerial survey n compete financially with other forms of survey.

Canadian Progress.—Canada has been the pioneer of this new dustry. Her vast and comparatively flat northern regions fered an ideal field for the young enterprise to prove its com- ercial value. Operations have for the most part been carried t by flying boats working from the numerous lakes and water- ys which intersect large expanses of unsurveyed and unex- oited forest land.

Two systems have been employed; vertical photography aided certain points previously fixed by triangulation; and oblique otography along a line already traversed by means of ground rvey.

Combined with aerial survey, a system of forest fire patrol has en established. During the forest fire seasons, constant air trols are maintained over important areas, and all fires ported by wireless to fire-fighting stations; in some cases, the e-fighting parties and apparatus are actually carried to the e of the fire in aircraft. Enormous tracts of timber have been ved by this means. In 1923, it was calculated that 2,120,000 res of forest were destroyed in Ontario; in 1924 the total struction was reduced to 140,000 acres, and the saving in bour totalled 50,000 man-days. The *United States* has followed nada in aerial survey progress. Her operations have included surveys, coast-line and river surveys, the alignment of new ads and railways, and municipal surveys and town planning.

France and Germany.—In France, a new law demanding curate plans of all fair-sized municipalities has led to much tivity in the survey of towns. In Germany, forest survey has en carried out extensively and successfully, and great progress s been made in solving the scientific problems connected with ereoscopic plotting and the aerial photography of mountain icts.

English Experience.—In England, owing to the fact that very curate surveys everywhere exist, operations have been con- ed to experimental work and research, together with a great al of commercial photography of estates, factories, etc. British aerial survey expeditions have, however, carried out most successful work in British Guiana, Burma and Borneo. Experience has enabled fairly reliable estimates of cost to be prepared, and it seems certain that complete and accurate aerial photographs of any normal area can be produced for from £3 to £10 a square mile, depending on the position and extent of the area to be surveyed. Triangulation on the ground is necessary for both air and ground surveys, but this price compares very favourably with any other method of filling in the topography of all except the most open type of country, while at the same time it gives considerably greater details with all necessary accuracy. It is likely that aerial survey operations will develop rapidly in the near future. One of the difficulties of the operator at present is that a single aeroplane can cover large areas so quickly that it is almost impossible to find employment for an aerial survey unit throughout the year, and so be able to distribute overhead charges over a really large area of operations.

III. GENERAL FLYING

Immediately after the World War, a large number of very cheap aircraft were thrown on the market. In several countries, but particularly in Great Britain and America, demobilised pilots purchased one or two aeroplanes and set out to make their living by giving the general public short flights in the neighbourhood of their landing place. The following figures show the measure of this activity in Great Britain:—

	Flights	Passengers		Flights	Passengers
1919–20	37,067	66,785	1922–3	13,578	25,253
1920– 1	23,513	36,694	1923–4	22,842	39,227
1921– 2	21,767	36,048	1924–5	23,519	43,766

This purely local flying was in some cases extended to the maintenance of aircraft plying for hire to carry passengers at a mileage rate to any required destination. The demand for this useful activity has proved small in England, but is likely to increase as operational costs are reduced. Joy-riding has served a useful purpose both in England and America in educating the public as to the possibilities of aviation.

In England an original use for aviation was devised in the introduction of sky-writing. A British company was formed shortly after the War and proceeded to advertise various commodities by means of writing their titles with smoke at a height of about 12,000 ft. in the air. This British company also obtained a large contract for advertising in the United States during 1922 and 1923.

IV. CIVIL FLYING SCHOOLS

Owing to the heavy cost involved, flying instruction to the general public has been very limited. In most of the greater countries, however, civil flying schools exist which depend largely on government assistance for their existence. In England there are five civil flying schools which undertake the annual training of officers. At these schools a private individual can obtain a very good grounding in the art of flying for about £100.

In France there are 11 civil flying training schools at Buc, Le Crotoy, Mourmelun, Orly, Angers, Nîmes, Orléans, Bordeaux Lyon, Clermont-Ferrand, Châlon-sur-Seine.

Pilots are trained for military purposes in these schools and it is from those who have had that military training that the civil aviation companies draw for their pilots.

In Germany there are three types of schools where the training of civil pilots is carried out:—

(1) Schools conducted by aircraft constructors; (2) schools conducted as an independent enterprise; (3) schools conducted by associations. In addition, there is an organisation known as the " Sportsflug " which has started six of its own schools.

In England a movement has just been started which will also give the private individual an opportunity of learning to fly. Private flying clubs have been formed which charge entrance fees and annual subscriptions to all members; at these clubs tuition on small aeroplanes can be obtained at low rates. The Government has guaranteed a certain measure of financial assistance to five of these clubs.

V. AIR RACING

The first form of air racing to come into being consisted of competitions between free balloons, the prize being given to the balloon which eventually landed at the greatest distance from the starting point.

The first recorded race of this class was the Grand Prix which took place in France in 1905. In 1906 the Gordon Bennett Challenge Cup was instituted and has been competed for ever since, with the following results:—

GORDON BENNETT BALLOON CUP WINNERS

PARIS—1906. Sept. 30—Oct. 1 1906.—*America*, Frank S. Lahm. Balloon, "United States" (2,080 cm.). Paris—Fylingdales, Yorkshire. Distance, 647·098 km. Duration, 22 hr. 5 minutes.

ST. LOUIS, U.S.A.—1907. Oct. 21–23 1907.—*Germany*, Oscar Erbsloh. Balloon, "Pommern" (2,200 cm.). St. Louis—Bradley Beach, New Jersey. Distance, 1,403·559 km. Duration, 40 hours.

BERLIN—1908. Oct. 11–14 1908.—*Switzerland.* Col. Schaeck. Balloon, "Helvetia" (2,200 cm.). Berlin—Bergest, nr. Bud. Norway. Distance, 1,212 km. Duration, 73 hours.

ZURICH—1909. Oct. 3–4 1909.—*America*, E. W. Mix. Balloon, "America II." Zurich—Ostrolenka, Poland. Distance, 1,121·110 km. Duration, 35 hours.

ST. LOUIS—1910. Oct. 17–19 1910.—*America*, Alan R. Hawley. Balloon "America II." St. Louis—Peribonka River, nr. Chicoutimi, Quebec, Canada. Distance, 1,884 km. Duration, 44 hr. 25 minutes.

KANSAS CITY, U.S.A.—1911. Oct. 9 1911.—*Germany*, Lieut. Hans Gericke. Balloon, "Berlin II." (2,200 cm.). Kansas City—Halcombe, Wis. Distance, 758 km. Duration, 12 hr. 28 minutes.

STUTTGART—1912. Oct. 27–29 1912.—*France*, Maurice Bienaime. Balloon, "Picardie" (2,200 cm.). Stuttgart—Riga. Distance, 2,191 km. Duration, 46 hours.

PARIS—1913. Oct. 12–14 1913.—*America*, Ralph H. Upson, Balloon, "Goodyear" (2,200 cm.). Paris—Bempton, nr. Bridlington. Distance, 618 km. Duration, 43 hr. 10 minutes.

1914 to 1919, inclusive—No contest.

BIRMINGHAM, U.S.A.—1920. Oct. 23 1920.—*Belgium*, Ernest Demuyter. Balloon, "Belgica" (2,200 cm.). Birmingham—North Hero Island, Vermont, U.S.A. Distance, 1,760 km. Duration, 40 hr. 15 minutes.

BRUSSELS—1921. Sept. 18–19 1921.—*Switzerland*, Capt. Paul Armbruster. Balloon, "Zurich" (2,200 cm.). Brussels—Lambay Island, Ireland. Distance, 766 km. Duration, 27 hr. 23 minutes.

GENEVA—1922. Aug. 6–7 1922.—*Belgium*, Ernest Demuyter. Balloon, "Belgica" (2,200 cm.). Brussels—Skollersta., Sweden. Distance, 1,115 km. Duration, 21 hours.

BRUSSELS—1924. June 15–17 1924. *Belgium*, Ernest Demuyter. Balloon, "Belgica" (2,200 cm.). Brussels—St. Abbs Head, Berwickshire. Distance, 714 km. Duration, 43 hr. 16 minutes.

Won outright by Belgium; replaced by *second* Gordon Bennett Balloon Cup.

SECOND GORDON BENNETT BALLOON CUP

BRUSSELS—1925. June 7–9 1925.—*Belgium*, A. Veenstra. Balloon, "Prince Leopold." Brussels—Cap Torrina, Spain. Distance, 1,345 km. (840 m.). Duration, 47 hr. 30 minutes.

In 1905, the French Aero Club founded the Fédération Aéronautique Internationale to control all international sporting aviation. This body has laid down and published a code of rules for air racing. The aero club of each country appoints delegates to the Fédération, which meets once a year, discusses modifications to the regulations, decides on conditions for current international competitions and investigates and ratifies claims for world's records.

The first aeroplane races ever held took place at an international meeting at Reims in Aug. 1909. At this meeting an international challenge cup for speed was presented by Mr. Gordon Bennett to be won outright by the country which was victorious three times running. Below are given the principal international competitions for aeroplanes and seaplanes with the results up to date:—

GORDON BENNETT AVIATION CUP

(Speed Contest)

REIMS—1909.—*America* (Representative, G. H. Curtiss). Distance 20 km. (12·4 m.). Time, 15 min. 50⅗ sec. Curtiss biplane, 30 H.P. Curtiss engine.

BELMONT PARK, NEW YORK—1910.—*United Kingdom* (Representative, C. Grahame-White). Distance 100 km. (62·1 m.). Time, 1 hr. 1 min. 4·74 sec. Bleriot monoplane, 50 H.P. Gnome engine.

EASTCHURCH, SHEPPEY, ENGLAND—1911.—*America* (Representative C. T. Weyman). Distance, 150 km. (94 m.). Time, 1 hr. 1 min. 36⅕ sec. Nieuport monoplane, 100 H.P. Gnome engine.

CHICAGO, U.S.A.—1912.—*France* (Representative, J. Vedrines) Distance, 200 km. (124·8 m.). Time, 1 hr. 10 min. 56 sec. Deperdussin monoplane, 140 H.P. Gnome engine.

REIMS—1913.—*France* (Representative M. Prevost). Distance 200 km. (124·8 m.). Time, 59 min. 45 sec. Deperdussin monopla 160 H.P. Gnome engine.

1914 to 1919, inclusive—No contest.

ÉTAMPES—1920.—*France* (Representative, Sadi Lecointe). Distance, 300 km. (186·5 m.). Time, 1 hr. 6 min. 17⅕ sec. Nieupor biplane, 300 H.P. Hispano-Suiza engine.

Won outright by France; replaced by Deutsch de la Meurthe Cup

HENRY DEUTSCH DE LA MEURTHE CUP

(To be won outright after two victories running)

1921—*France.*—Société Nieuport-Astra. Pilot: Georges Kirsch Villesauvage, Oct. 1 1921. Nieuport-Delage, 300 H.P. Hispano Suiza engine. Distance, 300 km. Time, 1 hr. 11 min. 39⅕ seconds.

1922—*France.*—Société Nieuport-Astra. Pilot: Fernand Lasne Villesauvage. Sept. 30 1922. Nieuport-Delage, 300 H.P. Hispano Suiza engine. Distance, 300 km. Time, 1 hr. 2 min. 11⅘ seconds.

Won outright by France; replaced by Beaumont Cup.

BEAUMONT CUP

(To be won outright by two victories running)

1923—No contest.

1924—*Istres.* June 22 1924.—Sadi Lacointe. Nieuport-Delag monoplane, 450 H.P. Hispano-Suiza engine. Distance, 300 km Time, 57 min. 50 sec. Speed, 311 km. (193·2 m.) per hour.

1925—*Istres.* Oct. 18 1925.—Sadi Lacointe. Nieuport-Delag monoplane, 600 H.P. Hispano-Suiza engine. Distance, 300 km Time, 57 min. 36⅖ sec. Speed, 312·5 km. (194 m.) per hour.

Won outright by France.

PULITZER TROPHY

(Speed Contest)

1920—*Mineola, Long Island.* Nov. 25 1920.—Lieut. C. C. Mosley U.S. Army. Verville machine, 600 H.P. Packard engine, Course 132 m. Time, 44 min. 29·57 seconds.

1921—*Omaha.* Nov. 3 1921.—N. Acosta, Curtiss Navy biplane 400 H.P. Curtiss C.D. 12 engine. Speed, 176·7 m. per hour.

1922—*Detroit.* Oct. 14 1922.—Lieut. R. L. Maugham, U.S. Army Army Curtiss Racer, 375 H.P. Curtiss D. 12 engine. Triangular course of 160 m. Speed, 206 m. per hour.

1923—*St. Louis.* Oct. 6 1923.—Lieut. J. A. Williams, U.S. Navy Curtiss R.2.C.1, 460 H.P. Curtiss D. 12 engine. Course, 124·28 m Time, 30 min. 36 sec. Speed, 243·67 m. per hour.

1924—*Dayton, Ohio.* Oct. 4 1924.—Lieut. H. H. Mills, U.S Army. Verville-Sperry cantilever monoplane, 500 H.P. Curtiss D 12 A. engine. Course, 124·7 m. Speed, 215·72 m. per hour.

1925—*Mitchel Field, Long Island.* Oct. 12 1925. Lieut. Cyrus Bettis, U.S. Army Air Service. Army Curtiss Racer, 619 H.P Curtiss V. 1,400 engine. Course, 124·27 m. (200 km.). Time, 2 min. 56·9 sec. Speed, 248·99 m. per hour.

THE JACQUES SCHNEIDER MARITIME CUP

(List of Winners)

Monaco, 1913.—M. Prevost (France) on a Deperdussin float seaplane, 160 H.P. Gnome. 150 nautical m. in 3 hr. 48 min. 22 sec (45·25 land m. per hour).

Monaco, 1914.—Mr. Howard Pixton (Great Britain) on Sopwith float seaplane, 100 H.P. Monosoupape Gnome. 150 nautical m. in 2 hr. 0 min. 16 sec. (86 land m. per hour).

1915 to 1918, inclusive.—No contest.

Bournemouth, 1919.—Race annulled because, owing to fog, no competitor covered the correct course; but as the Italian aviator Signor Janello, on a Savoia flying boat came nearest to covering the correct course, the competition was held the following year in Italy.

Venice, 1920.—Signor Luigi Bologna (Italy) on a Savoia S. 19 flying boat with 550 H.P. Ansaldo engine. 202 nautical m. in 2 hr. 10 min. 35 sec. (106·7 land m. per hour).

No English machines competed.

Venice, 1921.—Signor Giovanni de Briganti (Italy) on a Macchi 7 flying boat with 260 H.P. Isotta-Fraschini engine. 200 nautical m. in 2 hr. 4 min. 29 sec. (110·9 land m. per hour).

Naples, 1922.—Mr. H. C. Biard (Great Britain) on Supermarine Sea Lion flying boat with 450 Napier Lion engine. 200·2 nautical m. in 1 hr. 34 min. 51⅘ sec. (145·7 land m. per hour).

Cowes, 1923.—Lieut. David Rittenhouse (U.S. Navy) on Curtiss float seaplane C.R.3 with 465 H.P. Curtiss D.R.A. engine. 186 nautical m. in 1 hr. 12 min. 24⅘ sec. (177·38 land m. per hour).

1924.—British and Italian machines entered for the competition which should have been held at Baltimore. Italian entry did not mature and British machine crashed just before it was due to leave for U.S.A. Thus, if the American competitor had simply flown over the course, he could have claimed a win. As it was, the Americans declared "no competition."

Baltimore, 1925.—Lieut. Doolittle (U.S. Army) on Curtiss R.3 2 with Curtiss V. 400 engine, 191·4 nautical m. in 56 min. 6·37 :. (232·57 land m. per hour).

Air racing has done much as an incentive towards attaining ry high speeds, and although the actual racing machines are ually of small practical use, it has proved comparatively easy develop from them aircraft of great military value.

BIBLIOGRAPHY.—Very little literature exists which deals seriously th commercial aviation, but the following publications touch on various aspects and cover the details of most of its early history: dré Beaumont, *My Three Big Flights* (1912); C. Grahame-White d H. Harper, *Air Power* (1917); L. Hirschauer, *L'aviation de Transrt* (1920); H. B. Pratt, *Commercial Airships* (1920); G. Holt Thom- *Aerial Transport* (1920); Sir Walter Raleigh, *The War in the r*, vol. 1 (1922, etc.); Sir Ross Smith, *14,000 Miles thro' the Air* 922); C. G. Grey, *Aircraft Yearbook* (1923, etc.); Aero Chamber of mmerce of America, *Aircraft Year Book* (1925); Fred T. Jane . G. Grey), *All the World's Aircraft* (1925); E. H. Lewitt, *The gid Airship*, a Treatise on Design and Performance (1925).

(W. S. B.)

FLYING CORPS: *see* AIR FORCES.

FOCH, FERDINAND (1851–), French marshal, was born Tarbes Oct. 2 1851. His father's family had long been settled the south of France, leaving the district of Ariège in the 17th ntury to establish themselves as woollen manufacturers in e small town of Valentine where they took a prominent part municipal affairs. On his mother's side, Marshal Foch came a race of soldiers, his maternal grandfather having been a llant officer of the Grand Army. His father was a lawyer at rbes (Hautes-Pyrénées) who later became a revenue official; d he was frequently transferred from place to place, taking son with him. The future marshal thus received his education successively at the Lycées at Tarbes and Rodez, the semiry at Polignan and the Jesuit college at St. Etienne.

It was not long before his teachers were struck with his geometrical mind" and it was decided that he should enter e École Polytechnique, to prepare for which he was sent to . Clément's College at Metz. After a few months there, hower, the war of 1870 interrupted his studies. He enlisted in the antry but the armistice came before he saw any fighting, and returned to Metz to finish preparing for his examination. ne of his fellow-students has described how, in the midst of a sson, they learned, on March 11 1871, by the booming of the rman guns, that the treaty of peace had made Metz a city the German empire. None could foresee that the young udent was destined, as marshal, to restore the city to France. He sat for his examinations at Nancy, which was still occupied Manteuffel's troops, and was admitted to the École Polychnique, where he made his mark. In 1873 he was commisoned, and served successively at Fontainebleau, Tarbes and ennes. He then passed into the École Supérieure de Guerre here, after a tour of duty on the general staff, he was appointed professor on Oct. 31 1894. His lectures soon made a sensation, th by the evident soundness of the matter and the originality the form. Even thus soon his pupils bore witness to the excelnt qualities of their professor, who presently became one of e leaders in military doctrine. The lessons given between 1894 d 1900, collected in volumes, constitute the chapters of Foch's eat works: *De la conduite de la guerre* and *Des principes de la erre*, which appeared in 1897 and 1899.

In teaching six batches of staff college students Foch fortified s own military science as well; his years of Paris were in fact capital importance in the higher development of his intellect. hen he vacated his post no one doubted that he would return long in another capacity. After holding two regimental comands of artillery and spending a year on the staff of the V. rps, he was, so to say, imposed on the Government by the inion of the whole army as the fittest selection for the comand of the École de Guerre that he had made famous. It was emenceau—at that time Prime Minister—who made the pointment, giving him the rank of general, and from that y began the cordial relations between the great statesman d the great soldier which were to be revived later under memable conditions.

The general held his post as head of the École for four years, during which time he threw himself with untiring zeal into the work of this famous centre for military study, giving it a permanent stamp and forming a whole new generation of picked officers. When, in 1911, he was nominated to the command of the 13th Div. at Chaumont, Foch was one of the very few outstanding figures of the army and it was not surprising that, after a brief period in command of the VIII. Corps, the wish of everyone acquainted with the higher military personnel brought him to the head of the splendid XX. Corps, stationed about Nancy, which was accounted one of the best elements of the "Couverture." Thus, in 1913, he entered, to the sound of trumpets, the town where he had passed his examinations to the tune of the German army fifes and whence, before long, he was to march out for the War.

General Foch, who had married Mademoiselle Julie Bienvenue, had at that time three children—two married daughters and a young son who was destined to be one of the first to fall in the War. Although still attached to his Pyrenean home, the general spent his holidays on a small estate that he had acquired at Trofeunteniou in Brittany. In the summer of 1914 France was so far removed from any idea of attacking Germany that Foch had left Nancy to spend a month in far-away Brittany. A week later events led to his recall and he went into harness.

The Outbreak of War.—He was then a man of 63, but his rare moral, intellectual and physical vigour kept him singularly young. Foch was a man of thought and also, above all, a man of action. Gifted with an intelligence which was never allowed to be idle, ever widening the scope of his knowledge, reflective and delighting—to use his own striking phrase—to "phosphoresce," the great soldier is even stronger in will than in intellect. "Victory=*Will* . . . Victory goes always to those who deserve it by the greater force of *will* . . . A battle won is a battle in which one *will* not acknowledge oneself beaten"—these are but a few of the maxims found in his books, in which the word *will* occurs on every page. And in truth, although his grey eyes sparkle with intelligence, the forehead and, even more, the mouth reveal that will which he was able to communicate to all those who came in contact with him in the course of war. It is this will which gives such solidity to his character and protects it from all weaknesses. What is more, it stimulates both conscience and intelligence. He speaks of "these natures, hungry for responsibility, which alone turn out great men," and his own is one of these natures, that no sentimental considerations can either divert or check. For the rest, his clarity of mind translates itself by a realist and somewhat ironic common sense. "What is it about?" is a favourite phrase of his in all circumstances, for he believes in clear vision before direct action.

The XX. Corps formed part of the II. Army and Foch was therefore one of the commanders of Castelnau's army, which, on Aug. 19 1914, was thrown into annexed Lorraine. It will be remembered that this army, after some successes, came up against a formidable resistance in the region of Morhange and failed with heavy losses. Foch had had no part in forming the plan, which met with so cruel a check; he was but one of the executants. He had thrown his army corps resolutely at Morhange and, when repulsed, was still able to organise with perfect coolness its retreat on the solid positions of the Couronné de Nancy. Not content to await the enemy there, he resumed the offensive and, on Aug. 20, threw himself on the German regiments which were waiting to attack in the "gap of Charmes," and in overthrowing them prepared the victory in Lorraine. He was preparing to take his part there when he was called to the Grand Quartier Général, where Joffre entrusted him with the command of an army.

At that time the French were retiring in good order from Belgium and the Ardennes towards the region of the Marne. As a gap tended to open between the IV. and V. Armies, Joffre gave Foch the mission of forming a new army (the IX.) between them, co-ordinating his action with theirs. He was on the ground before the corps entrusted to him had arrived. In a few days he forged out of them a solid and supple little army which was already well in hand when the celebrated order of Sept. 4 arrested the retreat and prescribed the battle which was to lead to the victory of the Marne.

Foch, after passing the marshes of St. Gond, established himself on the heights which dominate the Petit Morin and of which Fère Champenoise marks the crest. It was thought that his rôle would be limited to supporting Franchet d'Esperey's army on his left. But when the German armies, which, instead of turning the left of the French armies as they had expected, were themselves turned on the right, they tried to penetrate the allied centre precisely in this region of Fère Champenoise and Foch had therefore suddenly to support the main strain of the battle, and that with troops inferior in number. The heights were for a moment carried by the Germans from Mondemont to Fère Champenoise. It was then that, by a clever manoeuvre, Foch rapidly transferred the 42nd Div. from his left to his centre and thus was able to gain the upper hand and force the enemy back. The extreme fatigue of his troops prevented him from pushing his successes, but he hung on to the retreating Germans and entered Châlons-sur-Marne behind them. His part in the victory of the Marne was capital and it was recognised by a glorious citation in general orders.

His reputation was so increased after this great crisis that Joffre immediately entrusted him with a new mission—this time one without parallel. Scarcely had the operations of the Marne terminated when, the two armies mutually trying to outflank one another, the "race to the sea" set in from the Oise to the Flemish coast which was only to be closed by the arrival of the Belgian Army and the formation of a continuous front right to Nieuport. The British corps, for their part, had been moved into the region of Ypres, while Joffre detached from the now stable front between the Oise and the Vosges all the forces that he could spare to meet a great attack between the Oise and the sea.

To co-ordinate the action of the heterogeneous troops hurriedly thrown into these regions, a leader of great authority was wanted at once to take the higher direction of the operations of the French armies and to co-operate harmoniously with the Allied armies so as to assure the co-ordination necessary to victory. On Oct. 4 Foch was sent to the Nord to fulfil this mission with the title of "deputy to the commander-in-chief."

He did not limit himself to giving the French armies, from Picardy to Flanders, the most energetic orders but put himself in close and cordial relations with Field-Marshal Sir John French and King Albert I., and established the essential liaison between the Allied armies. Ceaselessly finding the necessary reinforcements and dispatching them to the aid of the hard-pressed British and Belgian corps, he was able by his friendly and generous activity to impose his own resolute ideas and so make himself the soul of the battle of Flanders that, after the fierce fighting of the Yser and of Ypres, ended in mid-Nov. by the definitive check of the German invasion for the year 1914. In all this Foch had not merely confirmed his prestige as a strategist, but had won for himself the friendly admiration of his Allies so completely that, even then, it could be foreseen that if, one day, circumstances required unity of command there could be no better choice for it than Foch. Did not Mr. Lloyd George say: "He could not have done more for us had he been one of our own generals."

Foch was left therefore in contact with the British and Belgian corps in the capacity of general commanding the Group of Armies of the North. He held the post for two years and thus presided over the two Artois offensives of May and Sept. 1915 and the battle of the Somme in the summer of 1916 which the German attack on Verdun prevented from assuming the amplitude and decisive character that had been intended.

After brilliant initial successes the Somme battle seemed to sink in the autumn mud. The disappointment that it caused led to a movement of dissatisfaction with the higher leaders who had presided over it. Joffre having been relieved of his command, Foch was deprived of his also and relegated to Senlis for a mission of inspection. The story was that he was fatigued. This was hardly the case, but he accepted this semi-disgrace with resignation and his valuable advice was always at the disposal of General Lyautey, who had become Minister of War.

When, in May 1917, Gen. Pétain was called to the chief command, he himself suggested to the Government that Foch could be usefully employed in the post of chief of the general staff. Having been sent into Italy on the morrow of Caporetto to establish a much-needed understanding with Gen. Cadorna's headquarters, and having remained in constant and cordial relations with Field-Marshal Haig, there was little doubt that when the time came Foch would appear as the single commander that so many people desired by the end of 1917. When, in March 1918, the Germans launched their first grand offensive and the Allied line threatened to break, the necessity of this command became obvious to everybody. It was at Doullens that Foch, on March 29, received from the representatives of the French and British Govts. that mission of higher co-ordination that on April 14 became more precise in the form of the chief command of all the Allied armies fighting in France. Already he had grasped this command with a firm hand. Thanks to the close co-operation of the Allies he stopped the Germans at the gates of Amiens, and thereby brought about the final failure of their attempt to break the Anglo-French front and penetrate to the Channel.

Henceforward his whole energies were directed towards assuring this fruitful co-operation. Thus he brought strong French reinforcements to help the British armies, attacked in March and April, and engaged British and American divisions in the battle of the Aisne in May, thus twice checking German offen sives that, for a moment, were triumphant. And when th Germans came to a standstill in the pockets that they had drive into our front, he prepared the counter-offensives which, whe the hour struck, were to shake and crumple the German front.

The counter-offensive was on the point of being launche against the flanks of these pockets, from the Aisne to the Marne when, on July 15, a new German offensive took place. This met with a partial check which, as we know, had the effect o deepening the pocket in which Foch intended to grip the enemy The victorious attack of July 18 on the enemy's flanks force him to retire and gave the signal for the grand Allied offensives

Foch was now determined to halt no more. He realised tha the German armies were beginning to be exhausted but that i they were to be overthrown, the blows must fall thick and fas The great offensive of Aug. 8 in the region of the Somme whic as it gradually spread and became more violent, forced th Germans to retire on to the Hindenburg Line, was almost im mediately followed by the new offensive against that stron position where French and English vied with each other i valour. Once the line had been forced, Foch launched his famou "directive" of Sept. 3 which was in fact the programme of th general attack. The stages of this semi-concentric attack a well known. It stretched from the Meuse into Flanders an was designed to draw the enemy from all parts back on to th region of the Ardennes, where Foch hoped to pin them an grasp them. The "directives," which issued from the hea quarters of Bombon (and later, Senlis) are clear, resolute an pitiless. At this point Pétain, Haig and Pershing worked closest harmony with their French colleague. The directives Oct. 10 and 19 were followed by successes—hard won and u equal, it is true, but which on Nov. 5 culminated in the gener retreat of the beaten and exhausted German armies.

Foch, following them closely, had already prepared an oper tion on a large scale to make an end of them. While the Germa were to be thrown back into the difficult Ardennes region, a hu group of armies under the orders of Castelnau with Mangin principal executant, were to attack on the Moselle and the Sar and, reaching the Rhine, were to bar the line of retreat from t encircled Germans. It was at this point that the Germans ask for the Armistice. On Nov. 8 Foch, who had been engaged drawing up the conditions for three weeks past, received t German plenipotentiaries at Rethondes and, by his master attitude, brought them to accept all conditions on Nov. 1

taining with the occupation of the left bank of the Rhine the ults which he had expected to gain from the supreme battle.

The career of Foch was not at an end. Europe acclaimed him as e leader who had secured the victory. Marshal of France since ig. 7, he now became a British field-marshal and later a marshal Poland. He was elected a member of the *Académie française*, iich body, emulating the *Académie des sciences*, gave him a nderful reception, and at Paris, on July 14 1919, he passed der the *Arc de triomphe de l'Etoile* at the head of the victorious ops. From New York to London and from Brussels to Warsaw passed from triumph to triumph. He was not, however, con- nt with a parade rôle, and, as president of the Inter-Allied ilitary commission, he was repeatedly called upon to take easures in support of the action of the Allied Governments. is presidency he still retains—the last vestige of that single mmand of the armies led by him to the common triumph, the umph which was the outcome of that "will" always regarded him as the great and essential mainspring of victory.

BIBLIOGRAPHY.—Marshal Foch's own works are *Des principes la guerre* (1903), with English translation by Hilaire Belloc (1918); *la conduite de la guerre*, 3rd ed. (1915); *Préceptes et jugements du aréchal Foch extraits de ses oeuvres, précédés d'une étude sur la vie ilitaire du maréchal par A. Casset* (Nancy, 1919); with English anslation by Hilaire Belloc (1919). See also A. H. Atteridge, *arshal Ferdinand Foch* (1919); A. L. Grasset, *Le Maréchal Foch* 919); H. de Lacroix, *Le Maréchal Foch* (1921); P. Painlevé, *Com- ent j'ai nommé Foch* (1923). See also the Marshal's article on ORALE in this *Encyclopaedia*. (L. M.)

FOERSTER, JOSEF BOHUSLAV (1859–), Czech com- ser, was born Dec. 30 1859 in Prague, and studied under ibich. He became an organist and a writer on musical subjects; ter he was appointed professor at the Conservatoire in Ham- irg and eventually, in 1918, professor at the Conservatoire in rague. As a composer he developed from symphonic and amber music to opera, which formed the most important part his work. Foerster was a type of cultured musician, deeply notional in his resources, who replaced the vagueness of ex- ression which marked his early period by purity and technical erfection. His operas *Deborah* (1891), *Eve* (1897), *Jessica* 904), *The Unconquered* (1906), *The Heart* (1922) are dis- nguished by psychological depth and by the subjectivity of eir artistic understanding. Of his other compositions, the ost important are a symphony entitled *From my Youth* and a umber of suites.

FOGAZZARO, ANTONIO (1842–1911), Italian novelist and oet (*see* 10.590), died at Vicenza March 7 1911.

See Eugenio Donadoni, *Antonio Fogazzaro* (1913); L. Gennari, *ogazzaro* (1918); and F. Crispolti, *Antonio Fogazzaro; Discorso ommemorativo* (1911).

FOKKER, ANTHONY HERMAN GERARD (1890–), Dutch eronaut and aeroplane constructor, was born April 6 1890 at ediri, Java. He obtained his international pilot certificate in 911 and in the following year he established an aeroplane factory Johannesthal, near Berlin. In 1913 he founded another factory Schwerin in Mecklenburg and during the World War supplied e German Army with flying material, notably the Fokker bi- lane. After the War he returned to Holland and established the okker Aircraft Works in that country. In 1924 the Atlantic ircraft Corporation was founded in the United States, Mr. okker being a director; and a factory was started at Hasbrouck eights, New Jersey. Meanwhile he had set up a plant in Mad- d, which was already producing machines for the Spanish overnment. He devoted much of his time to researches in the eld of commercial aircraft development, one of his latest designs eing the Fokker triplane. His early experiments with regard gliding with motorless machines, of which he gave a demonstra- on in England in 1922, did not meet with very much success.

FOLKESTONE, England (*see* 10.600b), with a population of 7,511, has been improved as a seaport. Before the World War e harbour pier was lengthened to 1,480 ft., so that it now has erths for eight steamers, a railway platform and raised prom- nade along the whole length, and a lighthouse at the end. The area of the inner and outer harbours is a little over 12 acres. In 1915 there was a large landslip in the Warren; the railway line between Folkestone and Dover, which was buried or damaged for a distance of nearly two miles, was closed and was not reopened until Aug. 1919. In 1920 the Earl of Radnor presented the Warren and East Cliff to the town. A zigzag path has been built between the Undercliff and the Leas. In 1921 the foundation stone of an addition to the Royal Victoria Hospital was laid. In 1924 remains of a large Roman villa were excavated near the East Cliff, and the corporation undertook the roofing of a portion of the site, which contains a mosaic pavement.

Folkestone was an important embarkation point during the World War and one of the ports permitted to civilians. Many Belgian refugees passed through in the early days; it was estimated that 64,500 destitute Belgians arrived between Sept. 1914 and March 1915, besides about 44,600 who had sufficient money to pay railway fares for themselves. There were later large numbers of Canadian troops at Shorncliffe Camp near the town and also camps for American troops and for Chinese and Zulu labourers. On May 25 1917, during an air raid, a bomb fell in a crowded street, killing 33 people.

FOLKLORE (*see* 10.601).—Folklore, the science of popular beliefs, traditions and customs, has made great progress since 1910, especially in countries which till then remained more or less outside general scientific movements. Unfortunately scholars in countries like the Balkan States, Finland, Czechoslovakia, Yugoslavia, now publish the results of their work in their national language, thus adding to the difficulties of comparative study. This scientific decentralisation may perhaps culminate in concentration and standardisation, as has been effected in physical anthropology. The need for some such measures is evident. The scope of folklore needs to be defined. Its methods must be organised and, where necessary, renovated.

Scope of the Science.—Early students of folklore limited their studies to beliefs, tales, legends, myths, songs and games—that is to a great extent to "literary traditions." Early in the 20th century folklore was only a section of comparative literary history and of comparative mythology. But in some countries, as those under Habsburg rule and Slavonic areas, investigations covered the details of dress and ornaments, of houses and villages, of arts and crafts, as well as literary material. In these countries folklore was thus inevitably associated directly with ethnography.

While such conditions obtained, it was true that folklore was the ethnography of European peoples, and ethnography the folklore of the non-European peoples. Such indeed, but only as regards beliefs and popular literature, was the attitude of the Folklore Society of London, which in its publications has always granted equality of place to "primitive or half-civilised" savages, as to the peasants of Europe. Again, Sir James Frazer in his *Golden Bough* and in *Folklore of the Old Testament* has included all popular documents without geographical or chronological distinction. For him, as for the majority of folklorists of the older school, the term folklore referred only to intellectual, not to material, culture. Obviously the variations of dress, houses and implements have not, in Great Britain and the Central States of Europe, the same importance as in eastern and southern Europe, although certain areas, such as Scotland, the Alps, the Pyrenees and parts of Germany, have preserved vestiges of very ancient cultures.

Rütimeyer has discovered in Switzerland many prehistoric survivals, instruments, decorations, even modes of life. The Spanish Anthropological Society has started investigations in Spain into local fashions of dress, which have already yielded interesting results. In eastern and northern Europe the varieties of material culture and survivals of the Stone, Bronze and Iron ages are even more numerous and better preserved. In these countries, therefore, folklore has gathered in more such data than in those where it was first organised. The scope of folklore needs enlargement, so as to include the study of varieties of types of houses, villages, utensils of every sort, furniture, jewels, dress and every expression of popular art. Since the War, a movement in this direction has been started in England and in France by the publication of numerous monographs on country houses, too often in a purely utilitarian, rather than in a scientific spirit, because conditioned by the exodus of people in towns towards the country. But the investigations of Bancalari, Meringer and the school of students in Finland, Russia, Bulgaria, Rumania, Serbo-Croatia and Czechoslovakia into the material culture of those areas have been undertaken in strict accordance with the scientific rules of folklore.

Methods of Investigation.—The ampler the scope of folklore and the wider its domain, the more rigorously must its rules be determined. No single method of approach is adequate. The historical method is necessary—so also is the comparative method necessary; for in distinction from the historical method it does not put chronology into the first place, but compares the data according to their intrinsic nature, according to their technique and their external forms, without note of conditions of time and place. Frazer, Lang, Hartland and Westermarck in England, de Basset, Sebillot, Cosquin, Gaidoz in France, Mannhardt and his followers in Germany used this method, which had the advantage of bringing to light the gaps in the historical method of which the older philological method was but a secondary variation. A new philological method was founded by Edmond and Gilliéron, who published the great linguistic Atlas of France. Their study of words such as *Scier* forced them and their fellow workers to investigate things as well, such as *faux, faucille, segue, scie,* etc. Thus came into being a new scientific department, in which folklore and linguistics were united. So great was its success in Germany that Meringer and his pupils founded a review, *Wörter und Sachen,* in order to exhibit the scientific advantages of this combination. And so useful is it that modern folklorists are obliged to give heed to this class of investigations.

Human Geography.—Under the name of anthropo-geography or human geography (*q.v.*), the science of geography lends valuable aid to folklore. While the comparative method eliminated all conditions of place, geography regards them as essential. The union of the two has produced a new method which, so long as it holds a just balance, will continue to produce valuable results. As in modern linguistics, distribution maps are now essential in folklore studies. By this means the easy generalisations of the comparative school can be rectified, as has been done by Van Gennep for the Savoy area, where more than 630 parishes were examined, with the result that the generalisations of Mannhardt and Frazer, etc., were found to be not valid in the areas studied. There are local variations, and even disappearances of customs, which the older, comparative method failed to explain.

Not only must the data be strictly localised but they must also be related to all their concomitant conditions. In addition to the historical, linguistic and geographic qualities already mentioned, note has to be made of the psychological, economic and political conditions. In short, to make due progress, folklore must adapt the psychological method to its needs, as well as the sociological method, by which all elements in the social life are classified. Folklore is concerned with social and collective, not individual and isolated, phenomena—its very derivation proves this. A tale, a myth, a ritual act, a dance, a ballad, a mode of dress, a type of house, are collective expressions.

The Individual in Invention.—This does not mean that these are collective inventions. Every study of the growth of an element of this nature reveals an individual act as the origin or moment of borrowing—never the act of a large group. A small and limited group behaves as an individual just as the admirers of a popular poet, the followers of a prophet or the pupils of a painter or a sculptor form a school. Thus a new end is given to folklore. The comparative method has disclosed to us the dominant and constant elements for all mankind. This was necessary to ascertain the conditions in which these dominant and constant elements came into existence, by whom, how and why, variations in them are effected in distribution of place and time. In short, it is its business to discover the action of individuals, or of small groups of individuals, as well as the mental and material evolution of collectivities.

Collection and Preservation of Data.—The wider the scope of folklore, the more delicate become its methods of interpretation and the more necessary is it to gather its data in a strictly scientific manner. At the outset, complicated questionnaires were used almost at random. They are now prepared on a less ambitious scale and with more precise terminology. Personal experience goes to show that questionnaires are useful only if used by an investigator who has an adequate general knowledge of manuals and comparative studies.

Folklore Material.—The data of folklore fall into two series, intellectual and material. No great dictionary or encyclopaedia as yet exists to cover the first group of topics, as has been accomplished for other sciences. The only attempt in this direction in Europe is the *Folklore of France* by Paul Sebillot, in four volumes, which, but for the untimely death of this great pioneer, would have been followed by four other volumes; and in America the two volumes of the *Handbook of the American Indians* by Hodge (Bureau of Ethnology). In most countries recourse must be had to collections of monographs, such as those published by the Folklore Society of London, by Pitre in Italy, and by Machado y Alvárez in Spain. The work that has to be done in this direction could, and should, be accomplished by international co-operation. The Finnish authority, Antti Aarne, has drawn up a list of catch-words which, with items supplied by his co-adjutators, contains more than 3,000 items concerning specially the themes of tales and legends.

Museums.—The material data, implements, dress, etc., find their place in museums. But it is still rare to find a museum specially devoted to folklore, properly termed. Such are the Nordic Museum at Stockholm, the finest of all, then the Museum of Völkerkunde at Berlin; the folklore museums at Hamburg and Basel, the Museum of Popular Traditions at Paris (Trocadero), the national museums at Prague, at Bucharest, Cluj Klausenburg at Zakopane, at Warsaw and Cracow and at Budapest. In almost all big towns where there is an archaeological museum, there is a section set apart in it for folklore material, specially of historical and artistic nature. Of peculiar interest are sections of this kind at South Kensington, at the German Museum in Nuremberg, at the Landes Museum at Zurich, the Natural History Museum, Vienna, the Polytechnic Museum, Moscow, and the Alsatian Museum, Strasbourg. In most large provincial towns in England, France, Germany, Switzerland and Austria there are local museums which contain folklore objects, such as exhibits of ancient costumes, as well as coins, pictures and historic objects of every kind.

Nevertheless, the scientific organisation of folklore museums has not yet been founded. We are still at the simple stage of curiosity and rarity. The historical point of view in general overrules the special aspect of folklore interest according to which specimens should be collected and classified in technological and evolutionary series. The folklore material of non-European peoples is naturally much better represented, for it is ethnography pure and simple. The number of ethnographic museums has increased greatly in this period and their organisation improved, notably in the United States, Switzerland and The Netherlands.

BIBLIOGRAPHICAL NOTES.—*General:* The *Volkskundliche Bibliographie*, ed. by E. Hoffmann-Krayer (Berlin, 1919, etc.), deals with all elements in folklore and, in some degree, with ethnography. The *Gypsy Bibliography* by George F. Black (1914) deserves mention.

Manuals and Method: Charlotte S. Burne, *The Handbook of Folklore*, London Folklore Society (1914); Paul Sebillot, *Le Folklore. Littérature Orale et Ethnographie Traditionelle* (Paris, 1914); A. Van Gennep, *Le Folklore, Moeurs et Coutumes Populaires* (Paris, 1924); Luis de Hoyos-Sainz, *Etnografia, sus bases, sus metodos y aplicaciones á España* (Madrid, 1917); Karl Reuschel, *Deutsche Volkskunde*, 2 vol. (Leipzig, 1920–1); E. Hoffmann-Krayer, *Feste und Bräuche des Schweizervolkes* (Zurich, 1913); Jos. Schrijnen, *Nederlandsche Volkskunde* (Zutphen, 1916); Raffaele Corso, *Folklore, Storia, Obbieto, Metodo, Bibliografia* (Rome, 1923); F. W. Hodge, *Handbook of American Indians*, 2 vol. (Washington, Bureau of Ethnology, 1906 and 1910).

"Comparative" Works: (*a*) Beliefs and Customs. J. G. Frazer, *The Golden Bough*, 3rd ed., 12 vol (1907–15), abridged ed., 1 vol. (1922), *Folklore in the Old Testament*, 3 vol. (1920), and *The Belief in Immortality*, 3 vol. (1924; to be continued); E. A. Westermarck, *The History of Human Marriage*, 3 vol. (1921); Sidney Hartland,

itual and Belief (1914); Hutton Webster, *Rest Days* (New York, 16); R. R. Marett, *Psychology and Folklore* (1920); W. Wundt, *ölkerpsychologie*, 8 vol. (1910–24); L. Lévy-Bruhl, *La Mentalité rimitive* (1920).

(*b*) Tales, Legends, etc. J. Bolte and G. Polivka, *Anmerkungen zu n Kinder- und Hausmärchen der Brüder Grimm*, 3 vol. (1913–8); E. osquin, *Les Contes Indiens et L'Occident* (1922) and *Études Folklor- ues. Recherches sur les Migrations des Contes Populaires* (1922); . Van Gennep, *La Formation des Légendes*, 6th ed. (1923); Otto ank, *Psycho-analytische Beitraege zur Mythenforschung* (1919); lfons de Cock, *Studien en Essays over Oude Volksvertelsels* (1920); . Huet, *Les Contes Populaires* (1921); Macleod Yearsley, *The olklore of Fairy Tales* (1925); Von des Peyen, *Märchen, Sagen, etc.* 910 5); Antti Aarne, *Leitfaden der Vergleichenden Märchenforschung* Ielsingfors, 1913); and *Vergleichende Rätselforschungen* (Helsing- rs, 1918); Fr. Seiler, *Das Deutsche Lehnsprichwort* (1921–4).

(*c*) Periodicals and Collections. *Portugal.—Revista Lusitana*, the view of the Geographical Society of Lisbon and the Reports of porto University, edited by Mendes Correa.

Spain.—Acts and *Memoirs* of the Spanish Society for Anthro- logy, Ethnography and Prehistory, with a bibliography of works in panish dealing with all humanistic science, including folklore.

Basque Folklore.—Revue des Études Basques (Bayonne), the annual view and monthly bulletin of *Notes and Queries* by the Society of uske-Folklore founded by José Miguel de Baran in 1921 at Vittoria: so memoirs on the Basques by C. Schuchardt of Graz, N. Densu- anu of Bucharest, and M. Haberlandt of Vienna.

France.—On the death of Paul Sebillot, in 1918, the Société des raditions populaires was amalgamated with the Société française Ethnographie et des Traditions populaires which has published a view since 1919. The review *Melusine* has not appeared regularly nce the death of Eugène Rolland. Volume 13 appeared in 1912. egional reviews and the publications of academies and local arned societies contain much material. In the *Revue de folklore*, appear in 1926 under the direction of A. Van Gennep, provincial searches will be centralised.

The folklore of Northern Africa is dealt with in the *Revue tuni- enne*, and the *Revue africaine;* Western African folklore in the *Bulle- ns* published at St. Louis and at Brazzaville. In the *Revue indo- inoise* and the *Bulletin de l'École française d'Extrème-Orient* will be und material dealing with the folklore of India and China. The *ulletin de la Société des Études océaniennes* has articles on folklore.

British Empire.—Folklore, published by the Folklore Society of ondon, is both comparative and descriptive. The society also ublishes a collection of monographs dealing with the folklore of ngland under various headings. There are no special folklore re- ews for Scotland or Ireland, or, for the most part, of the Domin- ns; Canadian folklore finds a place in the *Journal of American olklore;* Asiatic folklore, especially Indian, is dealt with in the *ournal of the Asiatic Society of Bengal;* and Chinese folklore is also corded in the *Journal* of the North China Branch. The Chinese ociety also deals with such material from time to time. There are so local reviews and publications in the African territories which e not, however, centralised. As regards Australia, the publications the local geographic societies must be consulted.

Belgium.—The publication of *la revue Volkskund*, interrupted by e War, has now been resumed under the direction of A. de Cock, ictor de Meijère and J. Vercoulie. In Walloon Belgium *Folklore ubançon* has now commenced to appear in both languages under e direction of A. Marinus. The Belgian Folklore Society proposes publish a centralised bulletin dealing with folklore in both por- ons of Belgium.

Switzerland.—In spite of the War, La Société Suisse des Traditions opulaires has continued the publication of archives and separate emoirs and monthly bulletins dealing with Swiss folklore. Much formation has been collected and classified in the *Glossaire des atois de la Suisse romande* now appearing in instalments. The ictionary of patois suisse-italien has commenced publication, and cludes a description of material, objects, customs, etc., and dis- ibution maps covering northern Italy as well.

Italy.—For central and southern Italy, and especially Sicily, see e *Archivio italiano Tradizioni popolari* and the review, *Il Folklore aliano.* The review *Augusta Praetoria* deals with the valley of osta and neighbouring regions, and, from time to time, local or neral papers publish folklore material.

Germany.—All German folklore societies are united in the Verband eutscher Vereine für Volkskunde which publishes *Mitteilungen* eports). The Swiss society is a member, and the Scandinavian, utch and Czech-German societies also form part of this league. s reports deal with the activities of various societies under the rious headings of folklore. The best folklore reviews are:— erlin, *Zeitschrift für Volkskunde;* Munich, two reviews, *Bayerische efte* and *Bayerische Blätter für Volkskunde;* Giessen, *Hessische lätter für Volkskunde;* Leipzig, *Mitteilungen des Ver. für sächische olkskunde;* Breslau, *Mitteilungen der Schlesischen Gesellschaft r Volkskunde.* Further folklore articles, essays and bibliographies ill be found in *Anzeiger für deutsches Altertum; Archiv für dâs udium der neueren Sprachen; Archiv für Religionswissenschaft; örter und Sachen; Zeitschrift für Ethnologie.* The German output of folklore is by far the most important in the whole world because it is recognised to constitute an element in German nationality, and because the German country people are very conservative in their manners and customs.

Scandinavian Countries.—Most periodicals in Scandinavian countries publish folklore articles, such as, the *Danske Studier a Copenhague, Ymer* at Stockholm, etc. There are special reviews, such as, *Norsk Folkekultur* at Christiania; *Folkminnen och Folktankar* at Stockholm, and for Finnish Swedes *Folkloristiska och etnografiska.*

Finland and the Baltic Countries.—The Finnish-Ugrian Society publishes an excellent journal. The academy of Helsingfors publishes memoirs relating to the Ugrians, the Mongols, the Manchus, the Votiaks Voguls, the Tcheremisses and the Estonians. The Society of Folklore Fellows publishes at Helsingfors the well-known *Communications comparatives*, under the editorship of Antti Aarne. There are also folklore societies at Dorpat, in Latvia and in Lithuania.

Russia.—Nearly all periodical publications came to an end during the War and the revolution. Among them were *Zhiva 'ia Starina*, published by the Geographical Society of St. Petersburg, and *Etnografitcheskoye Obozrienie*, published by the Polytechnic Museum of Moscow. At Kieff, however, a laboratory of Anthropology and Ethnology has been founded by the Academy of Science of the Ukraine, which publishes a bulletin in Ukrainian, in which folklore is dealt with. In Manchuria a periodical appears, published by the local historical and archaeological society, and deals with Russian, Mongol, Manchu and Chinese folklore.

Poland.—While the review, *Wisla*, has ceased to appear, the Academy of Science at Cracow continues the publication of much material. The principal centre of activity is, however, at Lemberg, the headquarters of the Polish Society for Ethnology and Folklore. Its publication, *Lud*, is in its 23rd year, and appears simultaneously at Warsaw, Cracow, Posen and Vilna under the editorship of A. Fischer.

Czechoslovakia.—On the death of Zibert, the review, *Cesky Lid*, ceased to appear, but the *Narodopisny Vestnik Cesko-Slovansky* is still published under the editorship of G. Polivka. Other local reviews, notably in Slovakia, deal with folklore.

Austria.—On the break-up of the Habsburg Empire the scope of the Societies which publish journals of folklore has diminished; each element in the population prefers its own language as a means of publication so that there are local reviews in the Tirol, Styria, etc. Much folklore material is published by the Museum of Volkskunde and the Anthropological Institute in their publications.

Hungary.—Folklore material is centralised by the Academy of Science at Budapest, by the *Revue Ethnographique*, and in the reports of the Ethnographic Museum.

Bulgaria.—The Academy of Science publishes an important series of volumes on the popular manners and customs of Bulgaria.

Rumania.—The Bucharest Academy has already published some 50 vol. on Rumanian manners and customs. Then N. Densusianu has founded the review, *Grai si Suflet*, devoted to linguistics and to folklore. Local material is also published by the Universities of Jassy and Klausenburg.

Yugoslavia.—There are three important centres for folklore work in the country; the first at Belgrade where the Academy of Science and the university publish important memoirs from time to time; secondly, at Zagreb, where the review *Narodna Starina* (National Antiquities) is published under the editorship of Josip Matasovic; and thirdly, at Lubljana, where *Carniola* and *Mitteilungen des Museum-Vereines für Krain* are published. It may be indeed that Yugoslavia is one of the countries richest in folklore materials.

Greece.—The Hellenic Folklore Society founded by Politis at Athens, in 1910, publishes a review *Laographia*, to which also it has published as supplementary a collection of the complete works of Politis himself.

America.—In North America a distinct division of labour is observable. Indian folklore is centralised with the Bureau of Ethnology and the Smithsonian Institution and the *American Anthropologist.* The folklore of peoples of European and African origin falls to the *Journal of American Folklore* on behalf of the American Folklore Society, which also publishes memoirs. This society deals only with popular literature, tales, legends, songs, and not with popular material culture. Mention must be made here of the important investigations of Marius Barbeau on French Canada, and of Elsie Clews Parsons on the Bahamas.

Central America.—Gamio, in Mexico, deals with the folklore of the Indians in the publications of the Ministerio del Fomento. In Cuba, Fernando Ortiz has commenced publication of *Archivos del Folklore Cubano* (San Ignacio del Habana). Venezuela, Brazil and Chile are commencing publication of their folklore material, both of Indian and European origin. An annual bibliography of a complete nature, dealing with the folklore of North, Central and South America, has been published since 1917 by G. Rivet, of the Society of Americanists of Paris. (M. A. Van G.)

FOLKSONG: *see* SINGING.

FOOCHOW, China (*see* 11.271), a treaty port, had an estimated population, according to the Chinese maritime customs; of 320,900 in 1923. The streets have been widened and paved, the steps leading to the Long Bridge have been removed, and the road between it and the city planted with trees. Electric light has been installed, and also an ice-making plant to supply the fishing boats. In 1921 the Fukien Christian University was established on a site of 50 ac. below Kushan Point. The trade of Foochow has declined with the decline of the tea trade. The timber resources of the country are waning, and the trade in camphor is small. The demand for and the output of lacquer ware has increased. Ships discharge and load at the Pagoda anchorage, 10 m. below Foochow, since above this the Min river, divided into a number of channels, is obstructed by shoals and bars. A conservancy board was formed in 1919, and plans were worked out for directing the river into one channel, and permitting navigation by vessels drawing 17 ft. up to Nantai, the harbour of Foochow. The work was almost completed in the first and third sections in 1925, and the second section only required improvement by dredging.

FOOD, PURE (*see* ADULTERATION, 1.218).—It is only within recent years that the transfer of the manufacture of food from the home to the factory, and the transportation of food for greater and greater distances, have made it necessary for governments to promote systematically and scientifically the purity and truthful labelling of food products.

The purity of foods, drugs and other commodities was everywhere adversely affected by the conditions prevailing during the World War. There was a great increase in the practice of adulteration, and a marked falling off in the quality of manufactured foods. The use of substitutes and inferior products in times of shortage is a necessity; the subsequent restoration of higher standards is slow. Borax, formaldehyde and other food preservatives were tolerated to an almost unlimited extent in some European countries during the troubled period attending the War, and the users of these substances, after a few years of unmolested privilege, have been unwilling to give way.

Scientific Developments.—One phase of the movement for pure food was a proposal by the newly organised International Union of Pure and Applied Chemistry to study the practice of conserving foods by chemical means—a subject extensively investigated in the United States between 1904 and 1912. A report upon the laws governing the use of chemical preservatives in foods was presented at the fourth meeting of the International Union of Pure and Applied Chemistry at Cambridge, England, in June 1923 (Comptes-rendus de la quatrième Conférence Internationale de la Chimie, p. 133–6). The trend of public and scientific opinion at the present time is toward the complete elimination of chemical preservatives from foods. In addition to their own injurious action, food preservatives disguise the effects of putrefaction, and their use in many cases has put a premium upon the unsanitary handling of foods. Certain advocates, notably Prof. E. Paterno of the University of Rome, have defended the use of preservatives. It has been asserted that the extensive consumption of meats, preserved by boric acid or formaldehyde, as an exigency of war, produced no injurious effects. The lack of cold-storage facilities, such as are everywhere provided in the United States, has been advanced in many countries as an argument for the use of chemicals in preserving perishable foods. Legislation to exclude completely all foreign chemicals from foods has been held to be inconsistent so long as copper compounds, arsenates and other substances are permitted in agriculture as insecticides, fungicides and disinfectants, since traces of these nearly always occur in the fruits and vegetables so treated. Nevertheless opinion among hygienists, manufacturers and the general public is decidedly adverse to the use of chemical preservatives. It has been suggested that an important factor in the increase of certain diseases is the presence of chemical preservatives and metallic poisons in foods.

British Committee on Preservatives.—In England the Minister of Health appointed on July 7 1923 a Committee on the Use of Preservatives and Colouring Matters in Food. In accordance with their recommendations the Minister of Health announced on Feb. 17 1925 a Draft of Rules and Orders that completely excludes from foods boric acid, salicylic acid, formaldehyde, fluorides and all other chemical preservatives except benzoic acid and sulphur dioxide, which are permitted in minimum amounts for preserving a limited number of foods and beverages. According to these regulations a food preservative is defined as:—

> any substance which is capable of inhibiting, retarding or arresting the process of fermentation, acidification, or other decomposition of food or of masking any of the evidences of any such process or of neutralising the acid generated by any such process; but does not include common salt (sodium chloride), saltpetre (sodium or potassium nitrate), sugars, acetic acid or vinegar, alcohol or potable spirits, spices, essential oils or any substance added to food by the process of curing known as smoking.

It was objected that the new rules would operate to the detriment of both the trade and the general public on account of storage difficulties and of the increased price at which it would be necessary to sell food under the changed conditions. The new British Public Health (Preservatives, etc., in Food) Regulations of 1925 are to come into operation on Jan. 1 1927 with slight extensions of this date in the case of butter, cream and a few other products.

Standardisation.—A basic requirement in pure food control is the establishment of official standards of purity. The differences of opinion which prevail with regard to what constitutes pure sausage, marmalade, chocolate, catsup, ice cream and numerous other foods would make the task of the analyst an impossible one unless he had available certain recognised standards which are accepted as just by the trade and by regulatory officials. In Germany, Great Britain and the British colonies much valuable pioneer work has been done by the public analysts toward establishing standards of composition for many articles of food. In the United States a joint committee of nine experts selected equally from the U.S. Bureau of Chemistry, the Association of Official Agricultural Chemists and the Association of Dairy, Food and Drug Officials, by joint conferences with the trade, has established definitions and standards for a large variety of foods.

FOOD LAWS IN THE UNITED STATES

In the United States the control of foods is exercised by the Federal Govt. of the United States under the Federal Food and Drugs Act, the Meat Inspection Act, the Tea Inspection Act and certain Acts relating to specific products such as filled cheese, filled milk, butter and mixed flour. Forty-seven of the 48 states of the Union have some form of food control legislation. A number of states have laws which follow the general principles of the Federal Food and Drugs Act, but other states have laws differing very materially from that Act. In some states foods are controlled under the general provisions of one Act, in other states they are controlled under a number of Acts relating to specific food products. Each state has complete control of the foods produced and consumed within that state. The Federal Govt. has control of foods shipped into interstate or foreign commerce.

The Federal Food and Drugs Act, approved on June 30 1906 and amended in 1912, 1913 and 1919, provides in general that all foods coming within its jurisdiction be prepared in a cleanly manner from pure and wholesome materials; free from any added substances which might render them injurious to health; not labelled or sold under representations which are in any manner deceptive. Food packages must bear a plain and conspicuous statement of the quantity of the contents.

The Meat Inspection Act, approved on June 30 1906, provides that every establishment in which cattle, sheep, swine or goats are slaughtered or their carcasses are wholly or in part canned, cured, smoked, salted, packed, rendered or otherwise prepared, for transportation or sale as articles of interstate or foreign commerce, shall be inspected under the Act. The inspection begins when live animals are received for slaughter, and includes a thorough ante-mortem and post-mortem examination, a rigid inspection of products such as smoked or cured meats, lard and by-products, and a final inspection when meats and their products leave the inspected establishments.

The Tea Inspection Act of March 2 1897, amended on May 16 1908, provides that all shipments of tea offered for entry into the United States shall be inspected to see that they comply with the standards of quality and purity adopted each year by a board of tea experts appointed by the Secretary of Agriculture. Every consignment of tea offered for entry into the United States is inspected, and only such tea admitted as complies with the standards.

The Bureau of Chemistry in the enforcement of the Federal Food d Drugs Act endeavours to see that out of the great volume and riety of foods coming from other countries only such as comply th the Act are allowed to enter the United States. Shipments in olation of the Food and Drugs Act are denied entry into the iited States, and if not exported within three months are destroyed. the violation is a form of misbranding that can be entirely cor- ted by relabelling, the importer is permitted to relabel the ship- nt, after which it may be admitted to the country, if the relabel- g is correct. Foods that are harmful to health, however, are not mitted to the United States and must be exported or destroyed.

For the control of interstate commerce two forms of action are ovided by the Federal Food and Drugs Act—criminal prosecution ainst the party responsible for the violation, and seizure of any pments of adulterated or misbranded foods or drugs found in erstate or foreign commerce. Both actions may be invoked when cessary. Under the Federal Food and Drugs Act more than 000 cases, including both criminal prosecutions and seizures, have en terminated in the Federal courts and the results published in form of notices of judgment. This number represents only those tances of flagrant misbranding or adulteration in which court ion was necessary to check the practice. Countless minor viola- ns have been corrected by serving notices on the firm's responsible thout recourse to formal legal action.

Most of the grosser forms of adulteration and misbranding iich prevailed at the time of the enactment of the Federal od and Drugs Act and Meat Inspection Act in 1906 have been minated as general trade practices. Occasional sporadic in- ances on the part of widely scattered dealers to adulterate d misbrand in the old way are still detected at intervals, but ch practices are no longer general. New and more subtle rms of adulteration, however, are being detected. As a result the effects of pure food legislation by the Federal and State vernments, and by the application of the principles of sanitary ence in the food industries, very great improvement was made the purity of food in the markets of the United States between 10 and 1925. No other classes of merchandise are to-day, on whole, so free from adulteration and misbranding as foods.

FOOD POISONING (*see* 18.29).—The term food poisoning as ed by public-health workers and bacteriologists does not in- de the deliberate addition to food of poisonous substances th criminal intent, nor yet individual idiosyncrasy or sensiti- tion to certain proteins such as those contained in strawberries, gs, milk or shellfish. Food idiosyncrasy depends primarily a peculiar condition of the human body rather than on any ngerous quality in the food itself. The various "deficiency eases," such as *beri-beri* (*see* 3.774d), *scurvy* (*see* 24.517b) and chaps *pellagra* (*see* 21.69b) and *goitre* (*see* 12.191d), which are e to the lack of some essential element in the diet, are also not ially considered as types of food poisoning.

The manifestations ordinarily grouped as food poisoning at present time are those due to:—(1) the presence of poison- s substances in healthy, untreated plant or animal tissues; the introduction into food by accident, or design, of more less familiar organic and inorganic poisons; (3) the presence the food of living pathogenic bacteria or other parasites; (4) the esence in the food of poisonous substances elaborated by the owth of various micro-organisms.

Poisons in Plants and Animals.—Certain normal plant and animal tissues contain substances poisonous to man, and when eaten may cause illness and death; such are poisonous mushrooms and certain fish found in tropical waters. Fatal cases of oxalic poisoning from eating the leaves of the common rhubarb have occurred. Horses and cattle grazing free on the western ranges are frequently poisoned when forage is scanty and they resort to weeds and plants generally left untouched, such as the larkspur, the lupins, the water hemlock and the death Camas. Poisonous weeds eaten by cattle may indirectly produce poisoning in man. The disease known to the pioneer settlers in parts of the United States as *milk sickness* was early recognised to be connected with the occurrence of *trembles* in milch cows, but its origin long remained obscure. It is now believed that both *trembles* and *milk sickness* were due to a poisonous substance in the white snakeroot (*Eupatorium*) which was eaten by the cows when other pasturage failed.

Mineral Poisons.—Occasionally mineral poisons like arsenic and lead find their way by accident into food in the process of manufacture, as in the famous outbreak of *peripheral neuritis* (*see* 2.654) in several of the Midland countries in England in 1900, involving at least 6,000 persons and causing about 70 deaths. This was traced to the presence of considerable quantities of arsenic in the beer coming from certain breweries; it was found that the brewing sugars had been impregnated with arsenic by the sulphuric acid used in their preparation, the arsenic itself being derived from the iron pyrites used in making the sulphuric acid. More recently the cocoa sold by an English firm contained a small amount of arsenic derived from the potassium carbonate employed in its manufacture.

Long-continued action of food on containers may dissolve harmful metals such as lead, copper or tin. Tin poisoning from canned foods, although theoretically possible, is so rare as to have little practical significance, doubtless partly because such tin as is dissolved is largely fixed in an insoluble form by the solid portions of the canned food and eliminated directly from the body. Copper, although not a violent irritant, may have a highly injurious effect when absorbed during many years, as in the constant use of distilled liquors containing copper derived from the copper worm of the condenser; cirrhosis of the liver (*see* 16.803) may be caused in this way. Lead, owing to its well-known cumulative effect on the human body, is an undesirable substance to come in contact with food or drink. As long ago as 1767 the local malady of *Devonshire colic* was shown by Baker to be due to the action of cider on lead vessels. Lead poisoning has also resulted from the frequent use of acid beverages in bottles with lead stoppers. When lead was generally used in glazes and enamels for cooking vessels, recognised poisoning from these sources sometimes occurred; the enamelled ware at present in common use in England and the United States is lead-free.

Food Preservatives.—The use of food preservatives constitutes a very difficult and important phase of the problem of the addition of poisonous substances to food. Numerous substances have been added to food intentionally for the purpose of preventing the growth of micro-organisms and consequent spoiling. Some food preservatives (*see* 10.612) once widely used are now known to be poisonous for man as well as antiseptic for microbes and have been generally discarded or prohibited. Such are formaldehyde and hydrofluoric acid and their derivatives. Regarding some other preservative substances there is great diversity of opinion among those who have given the matter most study. The use of boron and salicylic acid compounds is generally, but not universally, disapproved. Benzoic acid, sulphurous acid and sulphites are regarded by many hygienists as permissible in certain foods under controlled conditions. The differences of opinion emphasise the insufficiency of our knowledge. Until information commanding the respect of all competent experts is available, it is well to err on the side of caution and minimise the use of preservatives.

The practice of adding poisonous substances to food merely for the sake of altering colour or appearance has nothing to recommend it. At the present time any danger of actual poisoning from colouring matter added to candy, pastries and the like is slight. In most countries the health authorities maintain a list of the substances, such as certain coal-tar dyes, which are permitted, and prohibitory regulation is strictly enforced. In the United States no colours and no preservatives in foods are permitted unless they are deemed harmless. (*See* FOOD, PURE.)

Bacterial Poisoning.—Food may serve as the vehicle for certain kinds of disease-producing bacteria and other parasites. In some instances the bacteria are exclusively of human origin and occur in or upon the food as the result of contact with sewage-contaminated water or through handling by a *carrier* of disease germs, *e.g.*, the contamination of oysters with typhoid bacilli present in polluted water and the contamination of milk by a typhoid carrier on a dairy farm. In other instances the bacteria present in the food are derived from an infection of the food animal. This second class of infections is especially important in any survey of food poisoning since the gastro-intestinal symptoms produced are often sudden and violent; many of the most typical and best known mass outbreaks of food poisoning belong to this group. The nausea, vomiting and diarrhoea that characterise these attacks usually attract attention to some article of food eaten shortly before. An attack of this kind rarely terminates fatally, and the symptoms pass off within 24 to 48 hours, having little after effect. Often a history of illness in the slaughtered animal can be secured. Some of the most extensive outbreaks of meat poisoning in European countries have been traced to the use of meat from an animal noticed to be ailing and promptly killed by the thrifty peasant as an emergency measure.

The bacteria that cause this typical form of food poisoning belong for the most part to the group of *paratyphoid* bacilli, organisms closely related biologically to the typhoid bacillus, but distinguishable by laboratory tests. Within the group of paratyphoid bacilli there are several different species (*e. g.*, *B. enteritidis*, *B. aertrycke*, *B. suipestifer*) that primarily cause disease in various domestic animals, but secondarily and occasionally give rise to food poisoning in man. Food poisoning from paratyphoid bacilli would probably be much more common than it is if foods were not usually cooked. These bacteria are killed by boiling, and the history of many attacks shows that, while parts of an animal eaten raw or partly cooked have given rise to illness, other portions cooked before being eaten have been quite innocuous. Sausages made from uncooked meat or internal organs (liver sausage, blood sausage, etc.) have been the cause of food poisoning in a disproportionately large number of cases. Unfortunately inspection of the meat before sale may fail to reveal any evidence of infection, so that protection against this form of food poisoning depends chiefly on (*a*) the selection of healthy animals for slaughter and (*b*) thorough cooking of all foods of animal origin.

Foods may be also contaminated with paratyphoid bacilli by the agency of rats and mice. These rodents suffer from natural infections with these bacteria and can become carriers. Rodent contamination must always be reckoned a possibility in investigating outbreaks of this type.

Certain of the higher animal parasites occasionally enter the human body in contaminated food. The small roundworm (*Trichinella*) that causes trichinosis is one of the best known. Thorough cooking is an effective safeguard.

Ergotism.—One of the earliest established instances of poisoning due to the products formed by the growth of micro-organisms in food substances is the disease of *ergotism* (*St. Anthony's Fire*) (*see* 9.738) so prevalent in the Middle Ages. Ergot is the poison formed by a fungus that grows on rye; in times of famine the enforced use of rye that would not otherwise have been eaten led to much suffering and many thousands of deaths.

Ptomaines.—It was long believed that many instances of gastro-intestinal disturbance—the typical food poisoning of the layman—were due to the products of various micro-organisms found in partly spoiled or decomposed food. Definite chemical substances—*ptomaines* (*see* 3.174)—were incriminated, and the expression *ptomaine poisoning* (*see* 22.629) came for a time to play as large a part in popular self-diagnosis as "influenza" or "the grip." In point of fact ptomaine poisoning, if it occurs at all, must be exceedingly rare. Ptomaines appear in food substances in the later stages only of putrefaction—after about a week! Alleged instances of "ptomaine poisoning" when investigated by modern methods may almost always be traced with greater plausibility to some other form of food poisoning. "Ptomaine poisoning" may be a convenient refuge from aetiological uncertainty; it is not a satisfactory diagnosis for illness or death.

The products of paratyphoid bacilli that have grown in food may in some instances be the cause of food poisoning, even when the bacteria themselves have been killed. The determination of this question presents great technical difficulties and has not yet been settled.

Botulism.—The most conspicuous and definite example of poisoning from a microbic product formed in food is *botulism* (*see* 18.30). The chief symptoms of botulism are nervous rather than gastro-intestinal. Disturbance of vision (double vision), great weakness and difficulty in swallowing, are common signs; there is little or no fever and the temperature may be subnormal; there is rarely any pain and the mentality remains clear; the disease is always serious, over 60% of the cases resulting fatally. From 1899 to 1924 in the United States 129 outbreaks occurred, affecting 435 people and causing 290 deaths. In the only outbreak known to have occurred in Great Britain (Loch Maree, 1922), eight persons were affected and all died. Botulism is due to a specific germ (*Clostridium botulinum*) which has great heat resistance and is also able to grow in the absence of oxygen. Under favourable conditions it elaborates a toxin which is one of the most poisonous substances known. Although the germ is widely distributed in soil in many parts of the world, the conditions necessary for its development in foodstuffs are so seldom present that botulism is one of the rarest of human affections. The lack of a suitable temperature, a certain degree of acidity of the culture medium, an over-abundant supply of oxygen, the presence of certain other micro-organisms are factors that may interfere with the growth of this organism and prevent toxin formation. Nevertheless scattered cases of botulism have occurred at intervals in Europe and America for over 100 years. The first cases to be described were caused by sausage, hence the name botulism. Meat pickled in brine has also been known to contain botulism toxin. In recent years canned foods of various kinds, vegetables as well as meats, have been implicated.

The majority of the cells of *Cl. botulinum* are killed by temperatures slightly above boiling, but a very small number may survive prolonged exposure to 115° C. or even higher.

The most obvious mode of protection against this form of food poisoning is to ensure cleanliness in all foods subjected to preservative processes and, in the case of heat-preserved foods, to use so far as practicable temperatures high enough to destroy the most resistant spores of *Cl. botulinum*.[1] The majority of canned foods proved to contain botulism toxin give sensible evidence of spoilage. The botulism toxin, unlike the organism that produces it, is readily destroyed by boiling. The immediate rejection, without tasting, of any food showing signs of spoilage and the re-cooking of canned foods before serving, constitute a second line of defence. If these precautions are followed, botulism already rare should become practically unknown.

FOOD PRESERVING: *see* CANNING.

FOOD SERVICE.—In the United States there has been, since 10, an increasing tendency on the part of Americans to take eir meals outside of their homes, *i.e.*, the growth of the community kitchen and its corollary the community dining room.

Community Kitchens and Dining Rooms.—Many reasons may assigned for this movement. In the first place it was a natural ep in view of the changes in the home itself: the urban home d become smaller, for every square inch of floor area, every bic inch of space, cost money in rent, and consequently the nctions of the home were limited so as to effect a reduction of ace. The home kitchen shrank first to the kitchenette and is w in process of vanishing entirely. Even where the space for elaborate kitchen is available, the problem of getting suitable rvants is so troublesome as to induce many to get along with minimum of domestic service, and, as the mistress of the house herself less willing to be a kitchen drudge than formerly, many eals are taken outside the home, particularly those of an borate nature. Private hospitality is more and more offered hired hotel space in preference to the home. Banquets and her special functions are easily handled in public dining rooms d involve little responsibility on the part of the host and hostess. he emancipation of women is another factor. Many women ve succeeded in establishing themselves, professionally or mmercially, before marriage. They prefer financial independce to keeping house. The small, compact, efficiently arranged artment is the result, with meals away from the home.

These factors are intensified by the constantly rising standards living and by the greatly improved marketing technique ich has stimulated a demand for many possessions previously n-existent or rare. Demands upon the family income have lvanced, encroaching upon the former budget allotment for nt and servants. Small and servantless homes come as a tural sequence. If even then the income is too meagre, the odern woman has no hesitation in aiding her husband to uble it by taking a position herself. Another blow to the home the chief or sole source of prepared food has been dealt by the tomobile and touring habit. It is estimated that in 1910 there ere in the United States less than 350,000 automobiles; in 25 over 17,000,000 were registered. Such an increase in the e of a personal means of conveyance with a day's travel radius say, 200 m. could not but have its effect on the food habits the nation. "Automobile" business is considered a substantial rt of the total business of hotels and restaurants.

The hotel kitchen, like its domestic counterpart, has had its oubles with its personnel, and for similar reasons. Working, wever, on a larger scale and increasingly on standardised oducts, it can make readier use of machines as a substitute for bour. The modern quantity kitchen is thinly staffed but splendly equipped. Washing-machines for dishes, glassware and ver, each adapted to the task in hand, enable two men to do e work of ten and to do it better. There is less breakage, the ver bears an enhanced sheen, and the bacteria count is reduced per cent. Dirt and filth, once the bugbears of any but the ost expensive dining places, are now perhaps more rare in tels than in the home. There are also the great mixers which, r example, beat up a bushel of mashed potatoes or a gallon of eam with equal facility, the steam-cookers, the potato-peelers d a host of smaller indispensables that save time, labour and ace where food is cooked on a wholesale scale. Electricity s helped in cookery and is now applied to refrigeration.

The Cafeteria System.—The service side of the problem has so advanced. The use of the steam-table has solved one of the oblems of public service by keeping dishes hot and food tasty ring the minutes or even hours that elapse between preparation d eating. The modern coffee-urn makes possible the preparaon of five gallons at one time, a difficult feat under the old ocedure. The newer methods of service bring the consumer and his food together without delay. The cafeteria system, under which all the dishes in the menu are displayed before the customer, who helps himself, has made quick service possible and cheap. Whatever losses there may be aesthetically, and these need be few, are broadly balanced by the pleasure of being able to make a direct selection of food. Incidentally, the cafeteria system has placed a premium on attractive, neatly arranged dishes. Another development, exclusively metropolitan, for those who want only a little food quickly, is that of the sandwich shop, luncheonette or expanded soda-fountain counter, where light refreshments are dispensed under conditions that permit high speed. Frequently these places are operated in chains, so that large numbers of sandwiches, for instance, are prepared in a locality where rent is low and trucked to small luncheon counters crowded into nooks that tap main streams of city workers. Such places appeal to the clerical worker or office girl who has little to spend and who seeks only a light lunch.

A closely related development is the delicatessen store, which sells prepared food but does not serve it. These, located in territories of concentrated population, present still another solution to the consumer's problems of limited space and few and high-priced servants. They eliminate much of the work and annoyance of cooking food in small, ill-ventilated apartments, while permitting the enjoyment of family privacy in consuming it. Similarly, in the large apartment hotels recently erected in the big cities, provision is usually made for extensive "room service." The kitchens of the hotel make it a part of their business to prepare meals which will be served in the rooms of the apartment dwellers. Special elevators and floor pantries assist, and special dishes and equipment have been devised to help keep the food in its best condition. Such a combination of wholesale cookery with individual service is practicable only in large, high-grade apartment hotels, but it has distinct advantages where conditions permit its use.

The conditions described are evident to all observers. Accurate statistics on the subject are lacking, however. Difficulties in the definitions of hotels, restaurants, boarding-houses and other eating places make current figures unreliable, and even less reliable the figures of 1910. Two estimates may be mentioned. The *Hotel Monthly* calculates that nearly 5,000,000 persons in the United States take a majority of their meals in public eating places and that they spend therein over 1,250 million dollars a year for a total of 4,000 million meals. *Hotel Management*, on the other hand, estimates that about 8,000 million meals per year are served outside homes and, taking a somewhat higher average amount spent (50 cents as compared with 35), reaches a figure of 4,000 million dollars of annual expenditure in public dining-rooms. This wide divergence between two competent authorities illustrates the difficulty of accurate estimate in hotel and restaurant statistics. It is evident, however, that the nation's restaurant bill might conservatively be estimated at over 1,000 million dollars a year. If the value of the food eaten by the employees and managers themselves and that sold for immediate consumption is included, but the canned and package-prepared foods omitted, a figure of 2,000 millions was probably too low rather than too high in 1925. (H. B. M.)

FOOD SUPPLY.—War influences the food supply in belligerent countries directly, and in neutral countries indirectly, through deterioration or distortion of agriculture, disorganisation of shipping, disintegration of finance and changes in consumption. During post-war reconstruction the abnormalities persist in modified form, broadly proportional to the severity and duration of the struggle, often attended by new disturbances contingent on inherent developments or proceeding from misdirected efforts at restoration of the *status quo ante bellum*. Sooner or later, a new equilibrium is established between agriculture, industry, transportation and finance.

During a war of large extent and long duration, agriculture suffers heavily in the belligerent countries and prospers seemingly in unadjacent neutral countries. After the war, agriculture recovers in the belligerent countries, but in the neutral countries undergoes liquidation. The governmental restraint of competition, effectual during war, is likely to be followed by excessive competition. It is from this panoramic viewpoint that a scrutiny of the results of the World War on the food supply of the world is to be undertaken.

I. THE WAR AND AGRICULTURE

Shortage of Men, Horses and Fertilisers.—No matter how categorically agriculture is classified as an essential industry in a country at war, the labouring forces of the land are drawn on by the military authorities. Landowners, tenants and hired workers are mobilised for military service. Horses are requisitioned. In the World War this recruiting of rural workers continued intermittently until the farm work was done largely by males past middle age and under 16, and by women. The working forces suffered in number, in skill and experience. Some replacement was effected by stationing prisoners of war on the land, but the agricultural result was everywhere inconsiderable. The requisitioning of horses made it necessary to use cattle as work animals, to the direct injury of the milk supply.

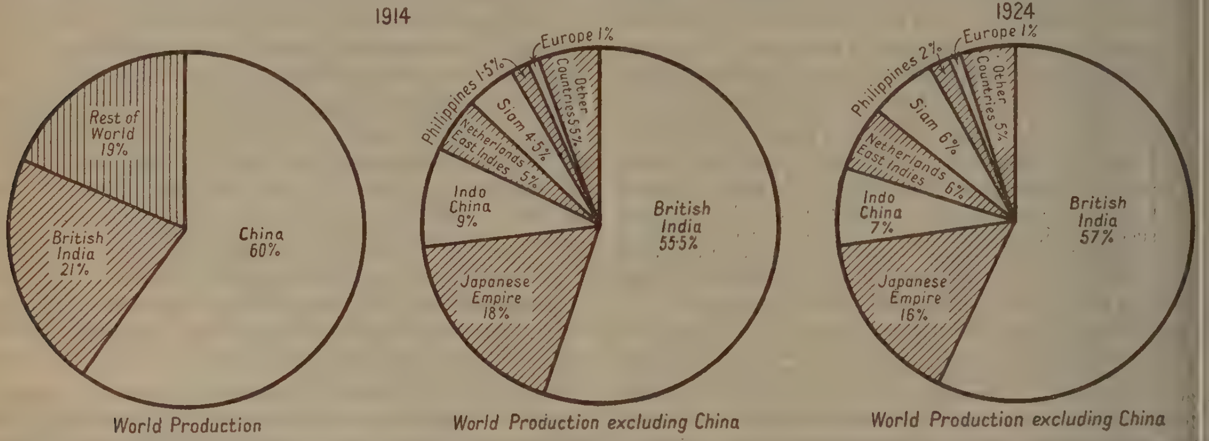

FIG. 1.—The total world production of rice in 1914 was estimated at 2,000,000,000 quintals. The total annual production of countries for which returns were obtained averaged 769,496,000 quintals for the period 1909-10 to 1913-4, and 849,415,000 quintals for 1924-5. The world's total production in 1924–5 was estimated at 1,300,000,000 quintals. (NOTE.—Percentages are necessarily approximate owing to incomplete data. No data is available for China after 1914.)

Only a partial picture of the effect of military recruiting is obtained by contrasting with the rural population the number of soldiers drawn from the land. The effect was more than the numerical ratio, and worsened progressively as the War continued. It was only by the redoubled and heroic efforts of old men, women and children that agriculture was kept going. Not alone human and animal forces were reduced, but material forces also. After the second year of the War there was practically no upkeep of implements. Deterioration of equipment rendered cultivation of the soil ineffective and imposed undue hardship on the workers, and agricultural practice became primitive and manual.

Pre-War European agriculture was heavily dependent on the use of chemical fertilisers, the supply of which declined rapidly. The United Kingdom drew saltpetre from Chile, phosphates from the United States and potash from Germany; under scarcity of tonnage and the munition demand for nitrogen, Chile saltpetre as a fertiliser became practically as scarce in the United Kingdom as was potash from Germany, and imports of phosphate declined. Despite huge domestic deposits of potash, Germany was unable to maintain the pre-War use of potash, though large amounts were applied to certain areas for particular crops in the vain hope of making good the lack of nitrate and phosphate. Since no imported phosphate rock was available to Germany, a grossly inadequate volume of Thomas slag remained her only source of phosphate. In France, the use of phosphate rock, saltpetre and potash declined to insignificant amounts.

In all belligerent countries, the by-product ammonia, previously largely used as fertiliser, went into munitions. Deprived of German potash, the agriculture of the United States was limited to the petty amounts of potash produced in War-born plants. Phosphate the United States had in abundance, until transportation became too congested to permit of normal movement. Saltpetre continued to be used on the soil in that country, though to a reduced extent. Sugar-producing areas, such as the West Indies, the Hawaiian Is. and Java, found their supplies of nitrate and ammonia greatly reduced. The neutral countries of Europe were little better off than the belligerents. Germany did, indeed, furnish potash to Holland and Scandinavia, as deliveries in blockade bargainings, but the amounts were small. Everywhere in Europe the prices of nitrate, ammonia, phosphate and potash became excessive for agriculture, when contrasted with the returned increments in crop yields.

The cumulative results of withdrawal of men and horses, deterioration of farm implements and lack of fertilisers operated in belligerent countries, so far as field crops were concerned, in four directions, mainly: (1) Acreage was reduced. (2) Yields per acre were lowered. (3) Weeds, pests and diseases had free run with corresponding deterioration of farm products. (4) The losses attending unfavourable weather were accentuated.

In general, the same situation held to some extent in the neutral countries of Europe. Men left the farms to take advantage of higher wages in industries. Horses were taken from the farms to be used in urban work or sold to belligerents. Farm implements were allowed to deteriorate, because the factories found it more profitable to manufacture war tools than to make replacement parts. Fertilisers were unavailable or expensive. Finally the agriculture of neutral countries suffered inordinately from disorganisation of natural markets through the operations of blockades. For the reduction in acreage and yield of the principal crops and the reduction in cattle, sheep and horses (*see* AGRICULTURE; GRAIN PRODUCTION AND TRADE).

Preference to Primary Foodstuffs.—It became a necessary War policy of agriculture in belligerent countries to use land for primary foodstuffs in place of raising feeding stuffs out of which meat and dairy products might be produced. According to common European practice, an acre of land devoted to bread grains would produce more than four times as many calories for human food in the form of flour as could be secured in the form of meat and dairy products if the land were devoted to animal husbandry. In the case of potatoes the economy in land was still greater. Contrasting beef cattle, hogs and dairy cows, the greatest waste of land occurred in the production of beef, the ratio of return being much greater in the form of pork or milk. On the other hand, cattle subsisted largely on forage not suitable for human food, while hogs were raised to a considerable extent on cereals adapted to human use or on special fodders grown on land that could produce cereals, potatoes or sugar. In order to make the best use of the land in terms of human nutrients, belligerent countries were compelled to reduce heavily the herds of swine and beef cattle. The count of dairy cattle was somewhat reduced, though efforts were made to conserve the milk supply.

As a result of these operations, some performed voluntarily by the easants and others executed under governmental orders, the count f cattle in Europe was reduced probably by 20–25% and of swine 0–40%. Despite the fact that sheep stood somewhat apart from attle and swine, the general result was much the same, though some ountries like Germany increased the number of sheep and goats. heep competed little with human beings for products of the soil or n the use of acreage, subsisting largely on feeding stuffs inappropriate to human use and grown on terrain unadapted to cultivation. n addition, wool was highly valuable; nevertheless, some countries howed a heavy reduction in the count of sheep.

The yield of meat and fat per animal was reduced owing to scarcity f feeding stuffs and to an abnormally high percentage of slaughter f immature animals. On the other hand, peasants concealed animals from the authorities, reporting fewer animals than they had nd delivering less of products that they produced. This duplicity n the part of the peasants was due partly to predilection for animal usbandry, partly to the greater profits of animal products as against ereals or other primary foodstuffs. The evasion thus described as least in evidence in Great Britain. In every country one found ter the War widely contrasting areas, some in which animal husbandry was most deplorably reduced, while in others the conditions ere practically normal.

It is difficult to compare estimates of acreage under cultivation nd counts of domesticated animals with those of the pre-War eriod on account of the changes in the map of Europe. It seems robable, regarding Europe (excluding Russia) as a whole, that the creage under cultivation and the count of domesticated animals as been restored generally to the pre-War level. The restoration of ultivated acreage has not been accompanied by restoration of pre-War yields, since there is still shortage of fertilisers. Also, the yield f meat and dairy products per head of animals is below the pre-War vel, due to shortage of imported feeding stuffs. It is difficult to ccomplish a restoration of animal husbandry in Europe until feeding uffs from Russia are again freely available. Broadly considered, the ecovery of European agriculture in the seven years after the World War was more rapid than was to have been expected, in consideration the extent and duration of the struggle.

Adaptive Devices of Agriculture.—Efforts were quite generally made the belligerent countries, following agricultural policies that aried in accordance with the characteristics of the region, to raise e maximum volume of foodstuffs in terms of calories. The agrarian ass everywhere had two motives: patriotism and price, though atriotism was perhaps less effective than price as a stimulant to roduction. In many countries peasants would give their sons without question, but not their crops, particularly not their animals. In der to stimulate production, farm prices were advanced, costs of stribution were reduced by establishing control of middlemen, and rices to consumers fixed at the lowest relative level possible; but the stems adopted worked out less well in some countries than in hers. As the burdens and costs of agriculture rose, the price demands of peasants increased. In every country the rural population elieved there was profiteering by urban industries, a belief which d to reprisals by agrarian classes in the form of pressing demands r higher prices for farm products. Governments everywhere were ying to satisfy the city with lower prices and the country with gher prices, usually failing in both directions. In some countries, rm prices of produce rose to four or five times pre-War figures.

In the neutral countries of Europe the situation was much the me. These countries were exporting farm produce to the belligerents. Usually the warring groups were bidding against each other. ach belligerent group used the power of the blockade to coerce the eutral countries of northwestern Europe. The governments of ese neutral countries were concerned with keeping the urban cost living down; but they had an interest in permitting the peasants to ploit the belligerents as much as possible. The peasants in neutral ountries had valid grounds for high prices, since the costs of agriculture and of consumers' goods had risen. They demanded coverage ices, then still more. Under these circumstances, in the neutral untries of Europe, as well as in belligerent countries, wherever ansportation permitted movements of foodstuffs and feeding uffs, there was a continuous trend towards higher prices for farm oducts, restrained or directed by governmental control, though actically unrestrained by competition between producers.

All growers of cane sugar were at the mercy of the Allies, and gar prices were definitely restrained; nevertheless, War prices were bstantially higher than those prevalent before the War. In belligerent Canada and Australasia, prices of essential foodstuffs rose adually throughout the War, particularly those destined for shipment to Europe. The neutral countries of South America were able secure relatively higher prices for essential foodstuffs, though the ices of some unessential foodstuffs declined. Raising wheat in gentina was a better business than raising coffee and chocolate in opical America.

The markets of the Central Powers were closed to neutral overseas countries by blockade; shipments from neutral overseas countries to the markets of neutral European countries were restricted by ocations by the Allies. Entrance to the markets of the Allies was stricted by governmental control over imports, attempting to parate essentials from non-essentials (*see* CONTROL), with the result that necessaries were able to command higher prices, while the prices of non-essentials declined heavily in the countries of origin.

II. EFFECT OF THE WAR ON CONSUMPTION

The *per-capita* intake of food was relatively reduced all over Europe, and absolutely reduced in the belligerent countries. Nevertheless, the *per-capita* food needs were higher in war than in peace; Europeans worked harder, wore poorer clothing, and heated their houses sparingly, all of which meant increase in food requirements.

In many belligerent countries it was impossible to secure a balanced diet with the requisite quantities of proteins and vitamins, and the situation became worse with each year of the War. With increased heat requirements, *per-capita* shortage of calories resulted in loss of body weight. Scarcity in the indispensable factors of the diet, together with a low intake of protein, resulted in retardation of growth of children, and in the development of marasmus and dyscrasias. Despite a quite general lowering of the birth-rate, in many countries morbidity and mortality were increased in children below the 10th year. Stunted growth was frequently observed between the 10th and 15th years; and the physical structure of many European children has been permanently injured by the nutritional disturbances of the War diet. The course of tuberculosis was intensified and the decline of the aged accelerated. Mere loss in body weight, quite generally observed in healthy adults in the countries of the Central Powers, was probably on the whole not an injury.

The pre-War level of consumption of food, in quality and in quantity, was not restored with peace. Indeed, in many parts of Europe, despite extensive relief operations conducted by the American Relief Administration (extending practically through three years following the Armistice), malnutrition and subnutrition persisted for years. Even in Jan. 1926 the diet of Europe in the comparative pre-War sense was, perhaps, normal only in Scandinavia, Spain, Portugal and Holland. The *per-capita* diet of the former belligerent countries is still probably somewhat subnormal in quantity and abnormal in respect of certain components, especially the relations of primary and secondary foodstuffs. Europe, as a continent, has to-day a notably heavier vegetarian diet than before the War, and this may be expected to persist for some time to come.

The diet of Europe is still probably deficient in fats. The supply of animal fats was reduced by slaughter of animals. Furthermore, the animals were insufficiently fed, and gave less milk-fat and less carcass-fat. Before the War Europe imported large supplies of vegetable oils. Russian export of vegetable oils ceased in 1915, and the blockade prevented edible oils from reaching the Central Powers from overseas. Scarcity of tonnage and marine warfare reduced the importation of edible vegetable oils to the allied countries. Importations into the neutral countries of Europe were reduced by blockade rationing. The effect was to lower the ratio between the fat and starch components of the diet of each country. Shortage of fat was more severely felt than shortage of sugar, and intensified the effects of shortage of milk.

The War induced modifications of the diet in many countries in Europe as the result of peasant reactions to governmental control. Illicit trade in foodstuffs, inevitable under any system of war control, became worse as the War continued and the technique of evasion was developed. (National pyschologies differed; there was comparatively little illicit food trade in England; in Germany it was rampant.) Food smuggling became a profession. As the War proceeded and the difference in price-returns between cereals and animal products became more extreme, the peasants concealed animals, delivered to market at the fixed price as little of animals and animal products as possible, sold as much as possible at high prices through illicit traffic, and increased the farm-household consumption. Milk, the most important single food for the urban population, suffered most because butter was the favourite article of illicit traffic. There was in most countries, therefore, a substantial degree of justice in the contention of urban Socialists, that the country districts were treasonably enriching the rural diet at the expense of the urban working classes.

This situation did not terminate with the War. Even after seven years of peace in many countries of Europe, of which perhaps Russia is the most notable illustration, the diet of the rural classes is richer in animal products than it was before the War; the diet of the urban classes is poorer. With deterioration of the buying power of urban workers since the War, this has had the result of increasing rural consumption of animal products; the town diet has become more vegetarian.

III. LIQUIDATION OF WAR CONDITIONS

The abnormalities in the production, marketing and consumption of foodstuffs during the reconstruction period were due to a variety of factors. Manufacturers who enlarged plants, making goods usable during peace as well as war, but subject to particular wastage during war, foresaw the dangers of such war expansion as would represent over-extension after the War, and in a variety of ways sought to evade the losses of post-War liquidations. The world still has unliquidated War expansions in flour-milling, sugar-refining, milk-condensing, food-canning, copper-smelting and leather-making, to mention only a few illustrations. Agriculture was generally urged to expand, with the result (naturally with exceptions in different countries and to different extents in different regions) that at the close of the War agriculture was over-extended by comparison with the pre-War position, and particularly with respect to the purchasing power of the world.

Over Europe the emphasis on the extension of primary foodstuffs, the reduction in the herds of domesticated animals, the scarcity of fertilisers and the deterioration of farm implements, together with the pressure to produce food stuffs to the maximum extent, led to the ploughing up of grass lands, to be used for the raising of primary foodstuffs. Agricultural authorities foresaw clearly the inevitable future repercussion of this movement. The policy of turning pasture to tillage reached its highest expression in the United Kingdom, and the deplorable post-War results are most clearly seen there, though observed to a lesser extent on the Continent.

Since the War, the agriculture of the United Kingdom has experienced a crisis as severe as that which characterised the period of agitation over the Corn Laws. British farmers have found that the enlarged area of tillage cannot be remuneratively cultivated; operative costs have been high, and the country has been deluged by agricultural produce flowing from overseas countries also suffering from War-expansion of agriculture. Throughout Europe, one of the results of agrarian distress, proceeding more or less from War over-expansion in the different countries, has been the revival of agrarian protectionist movements. This is not to be interpreted to suggest that Europe contemplates de-industrialisation in favour of agriculture; it represents merely a grasping at what seems to be an instrument of first aid. In part, it is a beggar-your-neighbour movement.

Cereals.—Europe may be expected slowly to recover her pre-War output of primary and secondary foodstuffs. This has been practically attained for cereals, and will soon be accomplished for sugar. In Russia, the recovery of agriculture has been most delayed, and the period of reconstruction may be notably prolonged. The recovery of agriculture is more rapid in western Europe than in the central countries between the Baltic and the Adriatic seas, on account of the higher natural position of agriculture, better railways, sounder fiscal policies and superior governments. Since the World War, western Europe has been compelled to secure a larger proportion of her imports of cereals from overseas, so that overseas countries have temporarily replaced Russia and the Danubian and Balkan States.

Sooner or later (probably sooner for the Danubian and Balkan States and later for Russia), these States will return to their natural position as preferred primary sources of supply of cereals for western Europe—for the one main reason, in addition to others, that these exporting countries must pay for necessary manufactured goods from western Europe with exports of cereals. During this time of readjustment the over-extended surplus-producing countries of North America, South America and Australasia face a gradual reduction in the scale of this agriculture, in so far as they may not be able to find new markets in the expanding population of the world.

The average acreage of the staple cereals in the United States during the years 1918, 1919 and 1920, was 230,000,000; the acreage in 1924 was 218,000,000. But for wheat the extent of liquidation represents a reduction of something near 20,000,000 acres. In the case of Canada, Argentina and Australia, there has been no such decline in wheat-growing. Indeed, the combined acreage in these three countries suggests continued expansion rather than contraction. When the definitive restoration of wheat-growing occurs in Eastern Europe, wheat-growers in Canada, Argentina and Australia will face liquidation with the development of a diversified agriculture, as has happened in the United States, or new markets for wheat must be acquired. The outcome will depend, among other things, upon development in the standard of living in the world, the penetration of industrialisation into Russia and Asia, and the competition between wheat, rice, millet and maize.

Sugar.—A good illustration of the disturbance in a staple foodstuff as a result of war is to be observed in sugar. Before the War, beet sugar and cane sugar competed internationally. Beet sugar was grown little outside Europe and Russia; cane sugar was grown in practically all tropical countries, and could readily be expanded. The production of beet sugar was greatly reduced during the War. The countries of western Europe replaced the beet sugar they had previously purchased from central and eastern Europe in part with cane sugar from overseas. A widespread expansion of sugar-cane growing followed. In some of the sugar-cane countries the planting is annual; in others the cane is cut, without replanting, over a number of years. When a new stand of sugar cane has been set and provided with transportation and refinery, this culture tends to persist, since sugar-growing is a form of agriculture associated with large capital.

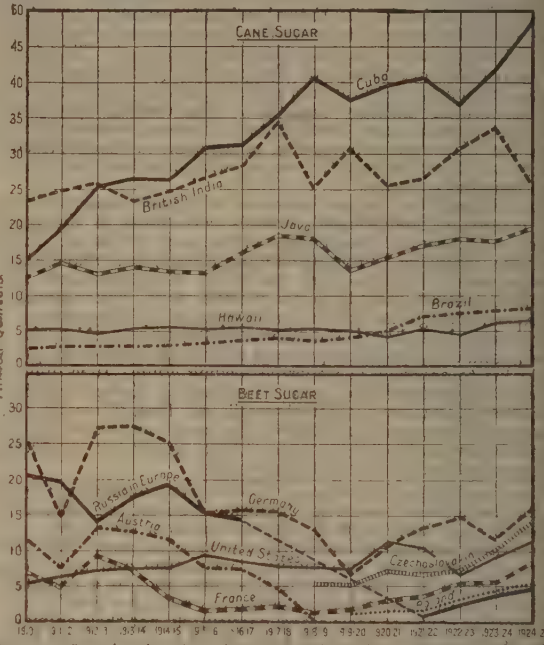

Fig. 2. -Graphs showing the production of raw sugar in the chief sugar-producing countries, for each year from 1910–1 to 1924–5.

In 1909–13 the world crop of beet sugar was about 8,000,000 short tons and of cane sugar about 10,000,000 short tons. In 1920–1 the world crop of cane sugar was over 13,000,000 short tons and of beet sugar only 5,000,000 short tons. Since then the production of cane sugar has continued to increase; at the same time, the beet-sugar areas are being restored. The sugar crop of the present season is over 17,000,000 short tons of cane sugar and over 9,000,000 short tons of beet sugar. When beet-sugar cultivation in Europe and Russia has been fully restored, unless there is some diminution in the output of cane sugar, the whole crop will be something like 18,000,000 short tons of cane sugar and 10,000,000 short tons of beet sugar. Can the world absorb this sugar? Certainly—at a price. Whether, with the restoration of the beet-sugar yields, the expanded cane-sugar acreage can be maintained or must be reduced, remains to be seen. In the meantime, the result for the world is a large supply of sugar at a beneficent price. Recent complicating developments are governmental restriction of cane-sugar production in Cuba and governmental bounty on beet-sugar production in Great Britain.

Other illustrations of agricultural expansions that became ansformed into problems of liquidation are cattle-raising in the nited States and Argentina and sheep-raising in Australasia. he expansion in cattle-raising in the United States was relative ther than absolute; none the less, the difficulties of American ttlemen have been due in good part to an increase in export of ef products from something like 150,000,000 lb. per annum st before the War to over half a billion lb. in 1918–9, with bsequent recession to the pre-War level. This restriction of tlet, together with other factors, has necessitated a heavy quidation. In the case of Argentina, the volume of the War arket for chilled, frozen and packed meats resulted in over-pansion of the industry, followed by a post-War crisis so severe to have prompted governmental action in price-fixing and bsidy. This also holds true of animal husbandry in Australasia, hich, despite the distance, was led to over-expansion as a re-lt of heavy demand for chilled and frozen meats during the ar. In Australia also, the crisis of liquidation found expression the use of public funds for the purpose of stabilising prices d minimising losses.

There is scarcely a country in the world in which some par-cular form of agricultural production was not over-stimulated uring the War. Hence, post-War problems of liquidation of rying extent and severity have everywhere arisen—writing-f of inventories and absorption of losses, liquidations imperative r the safe conduct of future business. Students of world agri-lture may agree that producers exploited the belligerent coun-ies during the War. They will also probably agree, a decade om now, that the gains of such profiteering have already been st, or more than lost, to the agriculturists as a whole, if not to articular individuals. And high food prices imposed on con-mers between 1915 and 1920 have since been requited by umping foodstuffs at less than the cost of production.

In particular countries, certain crops did not share in the World ar expansion but have nevertheless suffered in the post-War quidation. Of these, illustrations are wheat-growing in Aus-alia and sugar-raising in Java. Australia was too far from urope to have much call on ocean tonnage for shipment of heat, and wheat accumulated in Australia during the War. hese accumulations were exposed to heavy losses; grain is arketed in Australia in bags, storage capacity is limited, and rge amounts of grain were exposed to vermin and the elements. ustralia had no opportunity remuneratively to unload wheat n the world before the collapse of the wheat price in 1920. The tuation thus created was one of unusual gravity for the small opulation of the Commonwealth, and has found expression in ore or less continuous pooling and price regulation. In the se of Java, western European needs for sugar could be covered ith sugar purchased on money borrowed from the United States nd with a much shorter ocean haul. Thus the sugar industry f Java was stagnant during the War, and although it enjoyed short period of high prosperity just after the War, this was soon rminated by the collapse of sugar prices.

The history of sugar prices during and since the War furnishes good illustration of the contrast between correct statistics and correct opinions. Following decontrol of sugar, with the failure f purchase of the Cuban crop for the season 1919–20, the public, cluding sugar-producers, American importers, refiners, whole-lers, fruit-packers and candy-makers, assumed that the sup-lies available to the United States were short and inadequate her needs, that demand for sugar in that country would prove be quite inelastic, that sugar-hungry Europe would expand her nportations, and that the rest of the world contained no isible or invisible stocks of moment. On the basis of these ssumptions, a veritable trade hysteria resulted, culminating nally in a sugar price of some 23 cents. These stated assump-ons were all more or less unfounded, and as the facts became vealed the price of sugar declined precipitously. The Cuban pply proved larger than anticipated; consumers' demand in e United States was found to be relatively elastic; sugar-ungry Europe did not demand more sugar at high prices. In-ead of a shortage of sugar stocks throughout the world, sugar oured in from every conceivable direction. Hoarding was replaced by dumping. The huge gains in the spectacular rise of price (some realised, but mostly paper profits) were replaced by huge real losses that fell on producers, refiners and traders. Since sugar-beet growing in Europe is a long-view proposition, the recovery of this branch of agriculture was aided little by the price rise and has been retarded little by the price decline.

IV. CONSIDERATIONS BEARING ON MOVEMENT OF FOODSTUFFS

Despite the fact that the food supply is classed as the prime necessity of society, demand for foodstuffs is somewhat elastic and there is considerable variability contingent on adaptations and substitutions provoked by price relations. To a considerable extent, also, the distribution of foodstuffs is contingent on fluidity of finance; abundance or scarcity of credits has exerted considerable influence on the distribution of staples since the War. Credits from the United States, as well as the foreign investments of American nationals, tourist expenditures and immigrant remittances, have directly and indirectly facilitated the export of surplus agricultural produce from the United States, to some extent to the detriment of corresponding exports from Canada, Australia and Argentina. Public money has been used in Argentina and Australia in furtherance of the marketing of agricultural produce, and this, we may infer, to the injury of exportable produce from the United States. If surplus-producing countries employ public funds in furtherance of exports, the international movement of foodstuffs will be different from what would be expected if purely competitive relations obtain. It is difficult in surplus-producing countries to resist the political influence of agrarian blocs in their insistence on some form of relief through the use of public funds.

One post-War difficulty of agriculture, more or less general the world over, that finds expression in the food supply, has been the increased cost of labour. Without entering into the reasons for this advance in wages, it is sufficient to state that in most countries, both importing and exporting, the level of wages has risen substantially above the pre-War plane. To a considerable extent also labour costs have risen, since in many directions the efficiency of labour has not increased proportionately to the increase in the wage scale.

For many countries the position has been accentuated by the trend of movement of workers from country to city. Enlargement of wages of farm workers has resulted in increase in cost of production of farm produce. Since increase in wages of industrial workers has, at least to some extent, and in many directions, resulted in notable elevation in prices of industrial goods, this has had the effect of lowering the purchasing power of agricultural products in terms of goods and services. The measure for each year since the War in the different producing countries of the world of the purchasing power of staple foodstuffs—for example: wheat, corn, sugar, cattle, hogs, wool and coffee—amply confirms the broad fact. Only under special circumstances has the purchasing power of agricultural produce been raised relatively above the pre-War level. There is considerable readjustment in this direction to be expected the world over, since if such readjustment does not occur, this would imply a lower standard of living on the farm than in the town. This readjustment may be expected to include, from the side of agriculture, the elimination of submarginal areas and increase in efficiency of cultivation and management over the remainder; and, on the part of industry, increase in the efficiency of labour and improvement in mechanical operations, with resulting lowering of production costs.

A survey of the total commerce of the world in successive years since the War shows a relative overproduction of agricultural produce and a relative underproduction of industrial goods, though the margin is being gradually reduced. This has had the effect of lowering the purchasing power of agricultural produce in terms of industrial goods, which was relatively low at the beginning of the century and notably higher just before the War. After the War this relationship again became comparable to that existing at the beginning of the century.

The food supply of the world is modified by conditions of transportation, since both fluidity and cost of movement have influence on distribution and marketing. Transportation has been a limiting factor in the export of grains and oil seeds from Russia since the War. The railways of western Europe have been largely restored to their pre-War efficiency, except in the Danubian and Balkan States, whose crippled facilities still impose limitations on the movement of farm produce. The effective service of railways has been one of the outstanding features of the post-War situation in the United States and Canada. Ocean shipping rates have been low since the War, and this has facilitated movement to importing countries of surplus supplies from exporting countries the world over.

V. PROSPECTS OF THE NEAR FUTURE

Changes in the food supply of the world will depend to some extent upon developments in industry as well as in agriculture. During the period 1915 to 1925 numerous backward countries of the world increased their manufacturing facilities and thus rendered themselves less dependent on European goods. If these new industries maintain themselves, the retardation of recovery of European industries (whose output as a whole is still considerably below normal) will be prolonged, unless new markets and a higher standard of living in the world result in a general expansion of demand for manufactured goods. A point of particular importance is Russia. If the present low standard of living is continued in Russia, this will have an indirect effect on the food supply and manufacturing activity of Europe. The degree to which goods from manufacturing industries in India, China and the British dominions are able to supplant the products of corresponding industries in the United Kingdom, is another point of importance.

It is probable that the food supply of the world during the next 10 years (1926–36) will be relatively below the pre-War level and more vegetarian. It would be an error to expect the world to direct the first energies solely toward the restoration of the pre-War food supply, leaving the restoration of the standard of living in the matter of other goods and services to be deferred. Various groups of demands will compete in their claims on income, and the demand for food will not be able to secure a proportion of the income so large as to insure in the near future the restoration of the pre-War diet. The best that can be hoped for, so far as Europe is concerned, is to secure a diet competent in the nutritional sense; but a cheaper diet, less diversified, and less luxurious than was the case before the War. The agriculture of the surplus-producing countries will necessarily have to adapt itself to these developments.

We are accustomed in world trade to view manufactures from the standpoint of the international division of labour. If the food supply of the world is to be correctly appraised, it must be considered from the same standpoint. The world faces during the next decade the necessity of establishing a new equilibrium in the demand and supply of foodstuffs, representing a new equation between effective demand and remuneratively produced supply, a revised international distribution of labour in agriculture and manufacture, distorted, however, to an unforeseeable extent, by artificial controls, bounties and protective tariffs.

Since the War, Europe has been financing the importation of foodstuffs largely with borrowed money, credits, tourist expenditures and immigrant remittances. Before the War, Russia was a borrowing country; but, with Russia excluded, Europe was a lending continent. Outside of the United Kingdom, which remains a lending country, Europe, as a result of the War, has become a borrowing continent. With each year since the War, European governments, industries and even agricultures contract new loans at relatively high interest rates. Disregarding entirely European payments of War debts to the United States, the service charges on post-War European borrowings will represent a growing burden on the continent, a burden certain to be reflected in international trade, since the difficulties of transfers of international payments find their ultimate expression in the commerce of goods and services.

Ultimately, Europe must pay her international obligations with goods and services; but this is not to be expected during the next five or 10 years, during which time we expect adjustments to occur largely through the invisible items in the international accounts. But the time approaches when Europe must raise a larger proportion of her food supply or pay for a larger proportion of it with goods and services. The necessary adjustments contingent on these developments form part of the new equilibrium between demand and supply of foodstuffs toward which the world is inevitably trending. (A. E. T.)

FIG. 3.—World exports of refrigerated Beef, Mutton and Lamb. The increasing importance of South America in the supply of meat products is clearly seen by these diagrams, in which exports for 1910 and 1925 from each country are shown as a percentage of total world exports. (See Table.) The chief importing country is Great Britain, which takes some 60% of the world's available supply.

BIBLIOGRAPHY.—International Labour Office, *Enquête sur la Production* (1923); International Institute of Agriculture, *International Yearbook of Agricultural Statistics* (Annual); United States Department of Agriculture, *Agricultural Yearbook* (Annual); see also Reports of Ministry of Agriculture of Great Britain, etc.

The accompanying diagrams and tables illustrate the principal sources of food supplies, except wheat, maize, oats, rye and barley, which are dealt with in the article on GRAIN PRODUCTION AND TRADE, during the period 1910 to 1925.

Sugar.—The production of both cane and beet sugar greatly increased after 1910. The following table gives the exports of sugar in *short tons* from the chief exporting countries for the average of the period 1909–13 and for 1922.

Country	Average 1909–13	1922
Cane Sugar		
Cuba	2,009,899	5,581,376
Dutch East Indies	1,412,555	1,582,691
Mauritius	226,255	322,692
Brazil	38,284	277,903
Peru	146,736	302,447
Philippine Islands	179,432	399,112
Dominican Republic	92,351	189,195
Beet Sugar		
Germany	873,161	13,915
Austria-Hungary	848,830	..
Czechoslovakia	..	350,366
Netherlands	200,490	219,477
Russia	293,514	..
Poland	..	65,344
Belgium	154,476	177,594

The production of sugar in the chief producing countries for each year from 1910–1 to 1924–5 is shown in the chart below, based on figures given in *The International Year-book of Agricultural Statistics*. The total world production in the pre-War period and in 1924–5 was:

	Beet Sugar quintals	Cane Sugar quintals
Average 1909–10 to 1913–4	83,990,000	95,668,000
1924–5	81,690,000	150,845,000

Meat Products.—The table below shows world exports of refrigerated beef, mutton and lamb for 1910, 1913, 1917 and for each year from 1920 to 1925. Of particular interest is the great increase in exports owing to war demands, the growing importance of Argentina

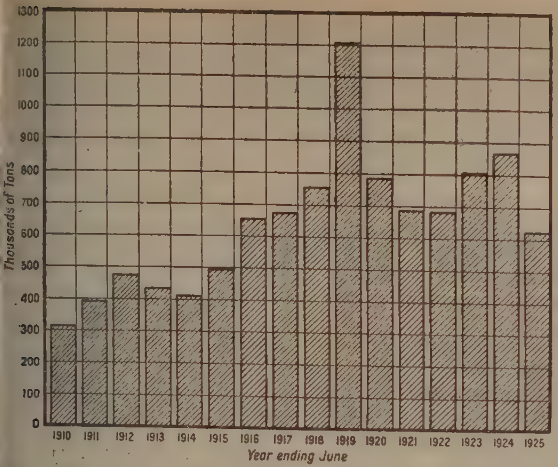

FIG. 4.—Exports of Pork and Pork Products from the United ates. The United States is the source of over two-thirds of the orld supply of pork products. This diagram shows the export of ɛsh, canned and pickled pork, cured hams and shoulders, bacon, d and neutral lard for each year from 1909–10 to 1924–5. The ief importing countries are the United Kingdom and Germany.

azil and Uruguay, and the decline in exports from the United ates. Exports from the chief exporting countries are shown in . 3 as a percentage of the total. The importance of the United ates as a source of pork products is clearly shown in fig. 4.

Exports, in Tons, of Refrigerated Beef, Mutton and Lamb, 1910 to 1925

Year	Australia	New Zealand	Canada	South Africa	Argentine	Uruguay	Brazil	U.S.A.	Other Countries	Total
910 . .	134,300	132,200	nil	nil	328,800	9,900	nil	23,900	nil	629,100
913 . .	178,500	122,400	nil	nil	412,200	30,100	nil	100	21,600	764,900
917 . .	116,500	120,100	55,000	21,100	448,700	72,300	66,400	97,900	37,500	1,035,500
920 . .	109,400	228,200	6,100	5,600	480,800	110,000	63,600	42,000	31,000	1,076,700
921 . .	95,200	212,200	4,300	1,000	456,400	82,700	61,000	12,500	45,000	970,300

FOOT AND MOUTH DISEASE: *see* VETERINARY SCIENCE.

FOOTBALL, ASSOCIATION (*see* 10.621).—The Football Assn. of England, having helped materially in the development of the game in Europe, made a departure in 1910 when, at the invitation of the South African Assn., a team of amateurs and professionals was sent in May to that Dominion. A successful tour carried forward the work of the Corinthians, who visited South Africa in 1897, 1903 and 1907. In 1920 another mixed team was dispatched to Cape Town. After years of preparation the Commonwealth Football Assn. of Australia arranged with the English Football Assn. to send out in 1925 a party of players, who were mostly professionals. The results of these excursions may be tabulated thus:—

	Matches	Won	Goals For	Goals Against
1910. South Africa . .	23	23	143	16
1920. South Africa . .	14	14	64	10
1925. Australia . .	25	25	139	13

Such enterprises were a continuation of the policy of the Football Assn. to popularise the game, the Dominion organisations paying the expenses and retaining all revenue. In 1917 the parent body in England presented a shield to Japan to foster the game in the schools of that country, and in the years immediately following the World War it gave challenge cups for competition to South Africa, Australia, New Zealand and Canada. To stimulate the game and to encourage English amateurism, the Assn. also entered teams for the Assn. football tournaments at the Olympic Games of 1908, 1912 and 1920, but withdrew from participation after the Antwerp Olympiad, as the definition of an amateur in England and the practice in some other competing countries were not in unison.

In 1910 the Football Assn. took another important step, as in April the rule regulating the maximum wages which could be paid to professionals by English clubs was removed. Such financial matters were deputed to the executives of the leagues, which thus became the controllers of all payments to professionals. The Football Assn. celebrated the jubilee of its existence in Oct. 1913 by a banquet, and to mark the occasion endowed a benevolent fund with £5,000.

During the season of 1913–4 a schism which had afflicted the game was brought to an end. As amateurs declined to co-operate in the government of all football, including professional clubs, a rupture had occurred in 1907–8. The Amateur Football Assn. was established and carried on a separate organisation until Feb. 2 1914, when representatives of the older universities and the Corinthians met the Football Assn. in conference and settled the dispute. The Amateur Football Assn. became affiliated to the Football Assn. under the same conditions as the Army Football Assn. and other auxiliary bodies. A momentous season was closed, King George V. attending the final match for the Assn. Cup at the Crystal Palace, London, on April 25 1914 and presenting the trophy to Burnley, who had beaten Liverpool.

Effect of the War.—In spite of the outbreak of the World War, the season of 1914–5 was carried through by league clubs employing professionals and therefore having legal contracts and commitments, but all the national associations cancelled their international matches, and in the spring of 1915 the Football Assn. took powers to suspend professionalism and all its cup competitions, although local tournaments for amateurs, for munition workers and soldiers on leave, were arranged by the

Football League. The Football Assn. imposed rigid conditions, and monetary inducements for men to play football were strictly forbidden. The Football Assn. and the league did much to assist the Red Cross Society, to provide comforts for the troops, and to help refugees in England. A football national war fund was founded in Dec. 1917 to relieve those connected with the game who had been stricken by the misfortunes of war, either on active service or in munition work.

Post-War Progress.—In the spring of 1919 the work of reorganisation was commenced and victory international matches were played. The season was lengthened by the addition of the last Saturday in Aug. in one year and the first Saturday in May of the year following, and a boom in the game was experienced in 1919–20. King George V. attended a league match for the first time at the Manchester City ground on March 27 1920 and witnessed the final match for the Assn. Cup at Chelsea, on April 23 1921, presenting the trophy to Tottenham Hotspur. In the next month the Football Assn. entered into an agreement with the British Empire Exhibition to play the final tie for a term of years in the stadium at Wembley.

The cup competition of 1922–3 is memorable for the first entry of the Corinthians and the first final played at Wembley. This match between Bolton Wanderers, who won the cup, and West Ham United attracted at least 150,000 people, the receipts being £27,776. The Football Assn. has also a cup which is restricted to amateur teams, and each year plays a charity shield match, which is quite apart from the £20,000 per annum that the clubs contribute to local charities. Receipts from the practice matches in Aug. are earmarked for this purpose by the Football Association.

Changes in Laws.—The International Football Assn. Board, which was established in June 1886 by the Football Assn., the Scottish Football Assn., the Football Assn. of Wales and the Irish Football Assn., have continuously revised the laws of the game at their annual meeting in June of each year. Gradually, but surely, forwards have been given more scope. In 1907 the board decided that a player is not out of play "when he himself is within his own half of the field of play at the moment the ball is played, or thrown in from touch by any player of the same side." At the meeting in 1920 it was resolved that "no one shall be offside when a throw-in is taken." In 1925 the board relaxed the fundamental law relating to off-side so that a player would be on-side if only two opponents were nearer their own goal than himself when the ball was last played by one of his own side. The board determined, in 1924, that a goal may be scored from a corner kick, and a year later the player, throwing-in from touch, was ordered to stand with both feet on the ground outside the touch line and facing the field of play, so as to throw the ball in over his head with both hands in any direction.

Football Leagues.—The Football League, founded by 12 clubs in 1888, expanded greatly after the World War. When the league considered the revival of the two competitions, on March 10 1919, the clubs in divisions I. and II. were increased to 22 in each section. On May 31 1920 the Southern League was, at its own request, absorbed by the Football League and became division III. in associate membership but without the right to vote at the annual general meetings of the league. On the same day a projected northern group, a part of division III., was sanctioned, but its formation was deferred until March 8 1921, so as to give clubs the opportunity to strengthen their playing power and secure financial stability. Thus the league had, for the season 1921–2, not only divisions I. and II., but both sections of division III., north and south each with 22 clubs. Thus the original membership of 12 clubs had increased to 88 clubs—a powerful alliance with authority to devise rules for their domestic affairs, although these must be in conformity with the rules and bylaws of the Football Assn. and sanctioned by the supreme body.

A Welsh National League, with northern and southern groups, was inaugurated in 1921–2. The Scottish League, which remained active during the War, had a moribund second division, but in 1923–4 this was galvanised into life by the adoption of the system of promotion and relegation. The first division was therefore no longer a closed corporation. The invigorated secon division was supplemented by a third division, so that the club of England, Scotland and Wales became classified into groups f the first time. The Irish Football Assn. had not the same oppo tunity, being limited to Northern Ireland. The Irish Free Stat founded a governing association body and created its own cu and league competitions.

INTERNATIONAL FOOTBALL ASSOCIATIONS

La Fédération Internationale de Football Association, whi is composed solely of the governing body of each country pla ing the game, was formed at Paris on May 21 1904, with th object of developing and controlling association internationa football. It grew so rapidly that, in 1910, the members includ Austria, Belgium, Denmark, England, Finland, France, Ge many, Hungary, Italy, Luxemburg, Sweden and Switzerlan During 1911, Ireland, Wales and Scotland joined, and the secre tary's report stated that all European countries with a governi body were members except Rumania. In 1912, with the Argenti Football Assn., and the pan-Russian Football Assn. include the Federation was recognised officially by the Internationa Olympic Committee, although Spain, Portugal and the Balka states were not properly organised. In this year, English becam the official language for minutes and correspondence, and it wa decided to adhere to the laws of the game as passed by th International Board of Great Britain. The Federation was ac mitted to this board with the right to send two delegates. Du ing 1913, Canada and Chile were affiliated, and when the Worl War broke out the Federation had 26 members, including th United States.

The Federation was dormant during hostilities, and when i was restored to activity the British nations withdrew from mem bership, as they declined to sit with the representatives of thos countries which had been their enemies. In 1924 they rejoin on their own conditions, which were that the articles of th Federation should not affect the inter-relations of the vario parts of the British Isles and their own autonomy. By Aug. 2 1925 the Federation had affiliated the governing bodies of th following: Argentina, Austria, Belgium, Brazil, Bulgaria, Can ada, Chile, Czechoslovakia, Denmark, Dutch East Indies, Ecua dor, Egypt, England, Estonia, Finland, France, Germany, Hun gary, Ireland, Irish Free State, Italy, Latvia, Lithuania, Luxem burg, Netherlands, Norway, Paraguay, Peru, Poland, Portuga Rumania, Russia, Scotland, Siam, South Africa, Spain, Swede Switzerland, Turkey, Uruguay, United States, Wales and Yugo slavia, with headquarters at Amsterdam. At a congress held i Prague in May 1925 the following resolution was passed: "Th congress of the Fédération Internationale de Football Assn. de clares that it considers the Fédération Internationale de Foot ball Assn. the highest authority on all football matters, and tha it cannot accept the interference or guidance of anybody else i such matters." At a conference between representatives of th four associations of the British Isles at Liverpool on Sept. 5 192 it was decided that the Fédération be informed that if this re lution were confirmed the conference would have no alternative bu to advise the associations of the United Kingdom to withdra from the Fédération. In Nov. the president and secretary of th Fédération officially explained that by Article 34 of its Consti tution the authority and competence of the International Boar were recognised and that the resolution applied only to "som powers strangers to football."

It is clear that association football has become a world gam In 1906 South Africa visited South America, and in 1923 a 1924 Chinese University students and a Canadian combinatio went to Australia. At the Olympiad of 1908 in London and 1912 in Stockholm, England won the international tournamen In 1920, at Antwerp, England was defeated and Belgium wo while in 1924, at Paris, the representatives of Uruguay were th victors. It has been difficult to organise comprehensive gove ment in countries of large area, but South Africa founded a association in 1892, Canada in 1912, the United States in 191 and the Commonwealth of Australia in 1921.

In the United States there has been much activity to make his code pre-eminent as the fall and winter game. During 1920 n American-born team from St. Louis visited Scandinavia, hile a Scottish set of players, under the auspices of the Third anark Club of Glasgow, toured in Canada and the United States n 1920-1. The sequel in the United States was the formation f the American Soccer League with a higher standard of play han had previously obtained in that country.

FOOTBALL, RUGBY (*see* 10.618).—The history of the game f Rugby since 1910, not only in Great Britain and Ireland, but n the British Dominions overseas and also in France, has been ne of steady development. Rugby is the national game in New Zealand and in South Africa, and to a less extent in Australia, while in a somewhat different way it is played in America. In France it has obtained the official recognition of the overnment, so that it is now played over the entire country. France possesses more clubs and more players than any other ation. In England many public schools, which have for years een devoted to the Assn. game, now play Rugby. Since the World War there has been a marked increase in the number f Rugby clubs in England, and the game is now played in many districts where at one time its very name was almost unknown. n the northern counties, which suffered so severely from the nroads of professionalism, Rugby is rapidly regaining its old opularity and prestige, and for some years now they have been ble to provide valuable members of the English team. The umber of old boy clubs, particularly in London, has been reatly increased.

I. THE BRITISH EMPIRE AND FRANCE

The year 1910 was an *annus mirabilis* for England, since t saw the opening of the national ground at Twickenham, Middlesex, with a brilliant victory over Wales. The revival of English Rugby may fairly be said to date from this year, for England won the championship for the first time since 1892, and rom then till 1925 has won it outright on five occasions, besides dividing the honours twice. The visit of the All Blacks in 1905 had demonstrated the weakness of the game in England, and or some seasons players had been endeavouring to improve both their tactics and their physical condition.

Much of the credit must go to A. D. Stoop, who persevered mid much discouragement in developing the open style of play, and who without doubt had his reward. He gathered ound him a band of brilliant halves and three-quarters, and fter a few years had the satisfaction of seeing his principles generally adopted and England gaining victory after victory. Next in importance to these tactics was the improvement in English forward play. For many years now the English selectors have aimed at discovering an all-round type of forward, clever with hands and feet and able to hold his own in the rough and umble of international matches. Forwards are no longer content to be mere pushing machines, their duties do not nowadays inish with the breaking up of the scrummage, rather do they hen begin. From 1910 to the end of 1925 England won 9 out f 11 matches with Scotland; 9 out of 11 with Ireland, the other being drawn; 8 out of 11 with Wales; and 10 out of 11 with France. That is to say, out of 44 matches England won 36, drew 3 and lost 5, a record probably without parallel.

Scottish Rugby.—In Scotland Rugby continues to flourish, new clubs are springing up and old ones are showing a decided ncrease in power and in the standard of their play. The national ide has achieved a very fair record since the World War, though t had to wait a long time for its first victory over England and or its first actual championship triumph since 1907. During he last few seasons Scotland has had to come south, especially to Oxford, for her three-quarters. Scottish forwards are as formidable as ever, the halves are sound, and, unlike England, Scotland has been fortunate in the possession of a succession of really first-class full-backs. The chief blots on the Scottish escutcheon since the World War are the three defeats by France, one of which was inflicted at Inverleith, where in 1921 France won by a try to nil. There are signs that Scottish Rugby is now at the beginning of a new era of prosperity.

Irish Rugby.—Irish Rugby naturally suffered severely during the World War, and also after it, owing to the disturbed state of the country generally. Indeed the wonder is, not that Irish teams have been defeated, but that they have been able to exist at all. But now old-established clubs are regaining their normal strength, and new ones are making good. During the last few seasons several international matches have been won, and the prospects for the future are bright. A number of young and promising players have been discovered, and Irish back play is developing well. The forwards too are recovering their old dash and are again a force to be reckoned with.

Welsh Rugby.—In 1910 Wales lost a sensational match to England, the first English victory since 1898, but they were still a formidable side, and in 1911 secured the international championship once more. Gradually Welsh Rugby began to lose its force, and triumph no longer automatically followed triumph. The World War dealt Welsh Rugby a very heavy blow, and although Wales gained a brilliant victory over England at Swansea in 1920, and carried off the championship in 1922, the Welsh game has not been up to its former standard. The curious point is that Welsh club football is practically as good as ever, or at any rate is still superior to English club Rugby, and Saxon victories over the great Welsh organisations are still few and far between. Yet the national side is no longer the force it once was, and the natural conclusion is that something is wrong with the principle of selection. Defections to the professional game now and again deprive Wales of potential international players, but not to an extent sufficient to explain the decadence of the Welsh fifteen.

French Rugby.—In France the game prospers amazingly. Reference has already been made to the three victories gained over Scotland. Ireland has also been beaten three times, but England and Wales have so far escaped defeat. England, it is true, had a very narrow escape in 1922, when the match at Twickenham ended in a draw, of which it is only fair to say that France had very much the better and were unlucky not to win. Tours in France are very popular nowadays with British clubs and they do an immense amount of good in more ways than one. French Rugby has suffered a good deal from the indiscriminate praise lavished on it in the early days, when it really needed constructive criticism, but the French authorities themselves were never misled, and always recognised the necessity of interchanging visits with British clubs and also of strict and adequate refereeing.

South African Rugby.—Since 1910 only two teams from the Colonies have visited this country. In 1912 a South African side, under W. A. Millar's captaincy, paid a visit which was remarkably successful. Of the 27 matches played, 24 were won and only three lost. A record was set up by their defeat of all the five countries, a feat no other touring side has rivalled. The matches lost were with Newport, London and Swansea. The strength of the team lay in the forwards, who were exceptionally powerful and fast, but the backs, if not as effective as those of the 1906 contingent, were by no means negligible.

In 1910 Dr. T. Smith, an Irish international, captained a British side in South Africa. It met with moderate success, winning 13 matches out of 24, and losing eight. Of the three test matches one was won and two were lost. About 12 international players took part, but the team was, of course, very far from representative of the full strength of Great Britain and Ireland. R. Cove-Smith led the fifth British team to tour in South Africa, but with rather unsatisfactory results. Of the 21 matches played nine were won and nine lost. Three of the four test matches ended in defeat, the other being drawn.

Persistent ill-luck followed the team in the matter of casualties, and the side, none too powerful to start with, was hardly ever at full strength. Indeed, toward the end it was difficult to find fifteen men sound enough to play. Most of the defeats were by comparatively moderate margins, but there is little doubt that the team was not strong enough for the task it undertook.

New Zealand Rugby.—In Sept. 1924 the second New Zealand team, captained by C. G. Porter, began a wonderfully successful tour. They actually won all their 28 matches in England, Ireland and Wales, no fixtures having been arranged in Scotland. Their triumphs were due to their splendid physical condition, and to their marvellous and intensive combination. Nothing finer has ever been seen in Rugby than the way in which the men supported one another; there was always somebody at hand to carry on and drive home an attack. They were naturally hardly at home in their first few matches, and they had a very narrow escape from defeat by Newport. But they steadily improved and in due course developed into a very fine side indeed, though in the opinion of many they were never quite the equals of Gallaher's men.

Tosswill, *Rugby Football* (1925). (F. J. SE.)

II. THE GAME IN THE UNITED STATES

The rules that govern American Rugby football were drastically changed in the winter of 1906 by a combined Rules Committee, six of whom represented the newly formed National Collegiate Athletic Assn., the other six being members of the old Rules Committee. This amalgamated committee was the outgrowth of a conference of representatives of a large number of colleges and universities which, because of the large and increasing number of deaths and serious injuries, was called for the purpose of doing away with football, or of radically changing the rules. This conference was a direct result of the football season of 1905 which had been marked by 21 deaths and by many serious injuries.

Changes in the Rules.—Vital changes in the rules were made at the meeting of this combined committee, these being on the following lines: (1) Doing away with heavy mass play, (*a*) by making it impossible for tackles and guards to be used as battering rams to precede the runner with the ball; (*b*) by doing away with "chain interference" and (*c*) by abolishing pushing and pulling of the runner with the ball. (2) Encouraging attempts to advance by throwing the ball forward, provided it was thrown across the line of scrimmage not nearer than five yards to the point where it was put in play. (This has since been changed to allow the ball to be thrown anywhere over the line of scrimmage.) (3) Stimulating kicking by making all players on the kicking side, except the centre, eligible to receive the ball as soon as it touched the ground. (This rule has since been rescinded.) (4) Encouraging the offensive team to take chances in free running, forward passing and on side kicking, by compelling the offensive team to make 10 yards instead of five in three trials. (5) Shortening the playing period of each half from 35 min. to 30 min., thereby reducing the strain. In 1912, each half was divided into two 15-min. periods, with a 2-min. interval to permit time to change goals. The above changes proved to be effective in doing away with serious injuries; also in opening up the game. Since then, comparatively few changes of importance have been made in the rules.

One of the most important changes occurred when the forward pass was allowed to be thrown anywhere over the line of scrimmage and at any time, provided the passer was at least five yards behind the line. This change, together with one allowing the man who first received the ball from centre to cross the lines of scrimmage at any point, permitted the doing away with the checker-board marking of the field, thereby reverting to the gridiron or cross marking that was in vogue preceding 1903. Another important change adopted in 1910 required seven men of the offensive side to be on the line of scrimmage. The development of the forward pass brought about a change in the shortening of the field between the goal lines from 330 ft. to 300 ft., with end zones of 30 ft. beyond each goal line in which forward passes could be completed. With the shortening of the field, the kick-off was moved from the centre of the field to the 40-yd. line of the kicking side. The value of a touch-down has gone through a series of changes, in which it has counted four, five and finally six points. In the same way, a goal from the field, whether from a drop kick or a place kick, has had a similar variation, but downward from five to four and finally to three points. Four trials instead of three are now allowed to gain 10 yards.

Development of the Game.—The game itself has developed in a most interesting way. Previous to 1915, it was rare to see a team which did not play its quarter-back close up behind centre to receive the ball and pass it to the runner, or carry the ball himself. Nowadays, however, none of the men in the backfield need play in specified positions all the time. The quarter-back calls the signals, but arranges the backfield in one of a variety of formations from which the center makes a direct pass to one of the backs. Probably the most common arrangement of the linemen is to have four on one side of the centre and two on the other, creating what is called the "unbalanced" line with a strong and a weak side. Some coaches instruct their players to assume these positions deliberately, the strong side being on the right or left according to the signal. Others have a preliminary arrangement of the guards or tackles lined up behind the centre and jump into position either to the right or left, thus forming a strong side.

A favourite backfield formation is to line one back, known as the wing back, slightly outside and a yard behind the end man on the strong side, while the other three men form a diagonal tandem, the back man assuming a position four to five yards behind centre. Sometimes one of the other two men forms a wing back in a similar position on the short side. Some teams play a "solid line"; others direct the end man on the long side to play out from one to two yards, while the end on the short side lines out from two to four feet, in which case the wing back on the strong side usually lines behind the opening. Another favourite formation is known as the punt formation, in which two backs usually arrange themselves in tandem from three to four yards back of the line of scrimmage on the right, while a single man stands about three yards back in a corresponding position on the left, and the fourth man from six to ten yards directly back of centre.

This formation lends itself peculiarly well to what is termed the "triple threat" style of play, in which the man farthest back may run, make a forward pass or punt. Shift plays are being used by many coaches; in these usually four line men assume a preliminary position from one to two yards behind the line of scrimmage and then jump into balanced lines or into lines with one man over or two men over, while the four men in the backfield adjust themselves in various ways according to the plan of the coach. Owing to the tremendous noise attending games, at some of which there are as many as 80,000, or 90,000 spectators, some of the teams use what is called the "huddle system." Instead of the quarter-back calling out a string of numbers with the players in their regular positions, he gathers the team around him and tells them the play. The team then quickly springs into position, and the play begins, either with or without a further signal.

Offence and Defence.—The offence in football has now reached a certain degree of standardisation after many years of experimentation of the widest divergence. Fortunately, offensive football will never be completely standardised, because the possibilities of manoeuvring the players are so many that coaches of inventive genius are constantly lured into the multifarious forms of strategy always possible to the clever tactician.

In defence, the general usage is to employ either a six or seven man line. If a six man line is used, the centre and four other men are arranged in what is called the 2–2–1 formation;

it is, two men backing up the line two or three yards behind it l separated from each other by three or four yards, while two ers line up about 10 yards back of the defensive ends, and safety man plays from 15 to 30 yards back. Another favour- style is known as the "box" defence, in which seven men y in the line with two men backing up the line from two to r yards back and three to five yards apart, while two other n play at points from 12 to 18 yards back and behind their pective ends. Many coaches still favour the "diamond" ence, in which seven men play on the line of scrimmage, ile one man plays from three to five yards behind centre and backs line up 10 to 12 yards behind the defensive ends, the ety man lining up 20 to 30 yards from the scrimmage. The ove three defensive formations have become quite standard- d. Some teams employ all three kinds, according to the part the field they are in and according to the number of the lown," the number of yards to be gained, also the type of mation the opponents are using.

Until 1926, the use of the forward pass has been encouraged ause it has made possible the playing of games between all and large institutions. In 1926 a new rule came into effect t a penalty of five yards is to be inflicted for every uncom- ted forward pass, after the first one.

Formerly, all school and college teams were coached by duates without salary. Later, paid seasonal coaches were ployed. In 1925, most coaches were members of the athletic partment. Since the World War, football in the United States had an unprecedented public interest. An era of stadia ilding has swept over the country, most colleges and univer- ies having built or planned to build one. Many high schools o have them, and several cities have erected stadia holding ,000 people. (A. A. St.)

FORAKER, JOSEPH BENSON (1846–1917), American poli- ian (*see* 10.628), died in Cincinnati May 10 1917. In 1916 he blished *Notes of a Busy Life.*

FORCED LABOUR: *see* SLAVERY AND FORCED LABOUR.

FORD, HENRY (1863–), American manufacturer, was rn on a farm near Dearborn, Mich., nine miles west of De- it, of William and Mary Litogot Ford. William Ford was of glish descent but born near Cork, Ireland, whence the Ford nily emigrated to America in 1847, settling near Dearborn. ary Litogot was born in the United States of Dutch parents. rs. Ford died when her son was 12. Henry Ford went to school til he was about 15, but worked on the farm after school hours d during vacations. He began early to develop an intense erest in mechanics. He was attracted first to watches, and at he took a watch apart and put it together again. In a little ile he was repairing watches and clocks throughout the sur- unding country, not for pay but because he had a burning riosity to see how watches and clocks were made. His only ls were a screwdriver made from a knitting needle and a pair tweezers fashioned from an old watch spring. All this work was ne at night; later it was done secretly, because William Ford jected to the son giving his services free. Also, he wanted boy to be a farmer, while the boy wanted to be a mechanic. At 16 Henry could no longer tolerate farm work. He left home, lked to Detroit, and apprenticed himself in a machine shop a weekly wage of $2.50, working 10 hours a day. His board d lodging cost him $3.50 a week. In order to make up the ficit he took employment with a jeweler from 7 to 11 in the ening, for which he received $2.00 a week. In about a year he rned from machine shop to an engine shop to learn something the building of engines. There he stayed two years. A com- ny manufacturing small steam engines for farm use needed man to install them; Ford took the place and for two years ore set up and repaired these engines. He had gone back to farm to live; there he spent all of his spare time in a little rkshop trying to build a farm tractor—for his experience with portable engines, as well as his own farm experience, had nvinced him that power should be put to work on the farm l that it was a waste to keep horses.

Eventually he built a single-cylinder engine steam tractor, but he could not devise a boiler to provide pressure enough to keep the tractor at work ploughing and yet be light enough for his requirements. For the time being he gave up his tractor until he could discover a more suitable boiler. Large steam tractors were already in use, but Ford's thought even then was in the direction of inexpensive, simple apparatus which could be bought by everyone.

In 1884 Ford's father offered him 40 ac. of land in order to draw him away from his mechanics. The land was mostly wooded. Henry cut the timber, set up a sawmill and sold lumber. In the summer he repaired farm engines. In 1887 he married Clara Bryant, who lived in the neighbourhood. He sawed the lumber for his house, which he built himself on his plot of ground, and having done this he moved his workshop from his father's farm to his new home.

Securing a job with the Detroit Edison Co. as an engineer and machinist he moved from the farm to Detroit, where he set up his shop in a shed at the back of his house. After hours he worked on the building of a gasolene motor car. In 1892 he completed it—although it did not run properly until the following year. This, his first car, had two cylinders with a 2½-in. bore and a 6-in. stroke, set side by side over the rear axle, and developed about 4 H.P., which was transmitted from the motor to the countershaft by a belt and from the countershaft to the rear wheel by a chain. He ran this car about 1,000 m. and then sold it for $200, in order to start the building of another car which would be lighter and stronger.

In 1899, feeling that he had the experience he needed, Ford left his job with the electric light company and went into the making of automobiles as a business, with a company, of which he was the chief engineer, known as the Detroit Automobile Company. He held only a small portion of the stock, and the company would not follow the lines of manufacturing to which he had committed himself. The directors wanted to make cars to order only; Ford had in his mind a universal car which could be made in quantities. In 1902 he resigned in order to go into business for himself—when the opportunity arose. In the meantime he rented a one-story brick shed and continued his experiments. He built several cars, two of them solely for speed. One he called the "999" and the other the "Arrow." Each had a four-cylinder engine giving 80 horsepower. The "999" won every race it entered, and in 1903, on the reputation of this speed car, Ford formed the Ford Motor Co., with a capitalisation of $100,000. Actually only $28,000 in stock was ever subscribed, and of this only about one-half was in actual cash. The company in 1926 had assets of about $1,000,000,000. It is the largest motor car company in the world and the third largest industry in the United States, comprising in itself about 50 other industries and employing some 200,000 people directly and an equal number indirectly. It has been built up entirely by turning back profits into construction. The company has never issued bonds or borrowed money; nor has it issued stock otherwise than to enlarge the original capitalisation so as to have it more nearly correspond with values.

The company is entirely owned by Henry Ford and his son, Edsel B. Ford, they having bought out the minority stockholders in 1919 for $70,000,000.

During its first year the company built a two-cylinder, 8 H.P. car with a chain drive, and of these 1,708 were produced and sold. In the second year the company made three models and for five years the company made various models of four-and six-cylinder cars. The automobile at that time was considered a pleasure vehicle, but Ford had conceived of it as a universal method of individual transportation and he was working to produce a light car of great strength, which would require a minimum of care and cost in upkeep. What delayed him was finding a steel sufficiently strong for his purpose, and it was quite by accident that he came upon a piece of vanadium steel, which was not then made in the United States. With that steel he designed Model T—which is what is known today as the "Ford car." In 1909 Mr. Ford announced that thereafter the company would build only one type of chassis, that it would be Model T, and that "Any customer can have a car painted any colour that he wants, so long as it is black."

The principles upon which the Ford industries are founded, as Mr. Ford has stated them, are:—

1. An absence of fear of the future or veneration for the past. One who fears the future, who fears failure, limits his activities. Failure is only the opportunity more intelligently to begin again. There is no disgrace in honest failure; there is disgrace in fearing to fail. What is past is useful only as it suggests ways and means for progress.

2. A disregard of competition. Whoever does a thing best ought to be the one to do it. It is criminal to try to get business away from another man—criminal because one is then trying to lower for personal gain the condition of one's fellowmen—to rule by force instead of by intelligence.

3. The putting of service before profit. Without a profit, business cannot extend. There is nothing inherently wrong about making a profit. Well-conducted business enterprise cannot fail to return a profit, but profit must and inevitably will come as a reward for good service. It cannot be the basis—it must be the result of service.

4. Manufacturing is not buying low and selling high. It is the process of buying materials fairly and, with the smallest possible addition of cost, transforming those materials into a consumable product and giving it to the consumer. Gambling, speculating and sharp dealing tend only to clog this progression.

In the Ford practice the cycle of production starts with the consumer. Mr. Ford holds that a commodity must first of all be designed to fit the needs of the largest possible number of consumers both in quality and price, and that the number of consumers will be continuously increased by constantly lowering the price of the article. At the same time, by paying the highest possible wages to those engaged in the production and distribution of the article, he creates a high buying power. In Jan. 1914 Mr. Ford raised all wages in his industries to a minimum of $5.00 for an eight-hour day. The average wage throughout his industries at that time was $2.40 for a nine-hour day. The minimum wage in 1926 was $6.00 a day, with an average of $8.00. Model T (the touring car), which in the beginning cost $850, in 1926, with the average wage about four times larger than then and with materials costing at least double, sold for $310, with a self-starter and many improvements. From the introduction of Model T on Oct. 1 1908 it took the company until Dec. 10 1915 to produce 1,000,000 cars, but under the new wage programme and the constant lowering of prices the company was in 1926 producing at the rate of 2,000,000 cars a year.

The general theory of production in the Ford plants is that everything must be kept moving and that the work must go to the man instead of the man to the work. For example, the cylinder block is cast on a moving platform in a mould made on a moving platform. Thereafter it passes, without stopping, through a series of machines which perform all the necessary operations, and then, still moving, it passes into assembly, where to it are added, one by one, the hundreds of parts to create a complete motor. Then it moves into the final assembly, where it is joined by other parts until eventually an automobile leaves the final assembly line under its own power. Every part of the motor car has a similar train of construction and assembly, all converging either into the final assembly or into boxes or freight cars for shipment. No man uses more than one tool, all the work comes waist high, a man never has to stoop or to move his feet to get anything, and the speed of the work is controlled not by the worker's will but by the pace of the conveyer.

The Ford industries have been steadily reaching back to sources in order to cut out intermediate profits. The industries have their own iron mines, coal mines and forests, their own railway, and an extensive fleet of lake- and ocean-going steamships, all of which are operated on the principle of high wages, high production and low cost. In the forests no tree is permitted to be cut under 10 inches. The logs are taken directly to the sawmill and, instead of being first converted into lumber and the parts sawed from the lumber, the parts are sawed directly from the log. All the wood-working is done at the forest mill, the waste goes to a wood distillation plant, and there is no waste whatsoever in shipment. At the River Rouge plant, the iron from the furnace goes directly into the foundries and is poured without reheating. The slag from the furnaces goes to a cement plant. A combination of electric furnaces and a large rolling mill converts all of the steel scrap. In every direction the pressure is toward preventing the waste of time, men or material.

As the business developed, it became apparent that it was a waste to assemble the cars at the factory and ship them complete. The manufacturing plants then ceased in effect to manufacture automobiles; instead, they make parts, and these are shipped to 35 branches in the United States, where they are assembled into complete motor cars. Similar branches or associated companies are located in nearly every part of the world and these branches also manufacture if the costs permit. Foreign branches, under the theory of building consumption, employ only natives of the country in which they are located. All the branches use the same methods and pay the same wages as the home plants. The industry does not use a single warehouse—everything is in transit.

The centre of the industry is at Detroit, Mich., and at River Rouge, Mich., on the outskirts of Detroit; but with the method of assembling cars at the point of use, a decentralising of manufacturing is taking place and comparatively small plants are being located out in the country wherever proper water-power sites are available. Each of these plants makes only a single part; the thought behind their establishment is to strike a balance between industry and agriculture. None of these plants employs more than 500 men, and in most cases the men divide their time between agriculture and industry. This is one of the most important developments.

Mr. Ford is firmly against paternalism in any form. He believes charity greatly harms those who receive it. Carrying out this thought, he has a trade school for the education of boys with dependents, in which the boys make useful articles. They earn an average of about $15 a week while receiving their education. The Henry Ford hospital in Detroit, which is open to any one, is conceived on the theory that a hospital should be self supporting. All its rooms are precisely alike, all have baths attached, all the fees and services are at a scheduled rate, which is the same to everyone, and all the surgeons, physicians and nurses are on salary and have no financial relations with the patients. The Ford Motor Co. also builds a light farm tractor under the same methods and principles as the motor car, and in 1926 was building experimentally all-metal airplanes and maintaining for experimental purposes a number of air routes with the eventual aim of putting the Ford principles into aeronautics.

Henry Ford has taken no active part in politics, although he was nominated in 1918 for United States Senator from Michigan; at the election he was defeated by a small margin. He took no part whatsoever in the campaign. In 1915 he was convinced by certain peace advocates of foreign extraction that it might be possible to end the World War if a sufficient gesture were made. He thereupon chartered a ship and proceeded to Christiania, Norway. Then, convinced that the mission was futile, he returned home. Mr. Ford does not believe in war, but he is not an active pacificist. For this *Encyclopaedia* he wrote the article MASS PRODUCTION.

A full account of the origins, theories and practices of the Ford industries is contained in *My Life and Work* (1922), and *Today and Tomorrow* (1926), both by Henry Ford in collaboration with Samuel Crowther. (S. CR.)

FOREIGN LANGUAGES, TEACHING OF.—The revolution that has taken place in the methods of teaching modern languages may be said to date from Viëtor's pamphlet *Der Sprachunterricht muss umkehren* (1886). His doctrines were largely adopted in the Frankfurter Reformschulen, but it was not till after 1900 that the movement became widespread in England and France. Broadly speaking, the idea of the reformers was to substitute direct comprehension and acquisition of the foreign language for mere knowledge attained through the medium of the mother tongue.

They insisted on oral study at the outset of the language, involving explanations in the foreign tongue itself, on inductive ethods of learning grammar and on the use of reading and of ee composition in place of formal grammar and translation om or into the foreign language. Hence the introduction of ie phonetic script and chart; the employment of gesture; the ilisation of pictures, postcards, coins and other *Realien;* and ie stress laid on the teacher and not the text-book being the ntre of the instruction—the whole idea being to render the assroom a sort of French or German *enclave*, and to make the ipil think as far as possible in the language.

Some of these doctrines were pushed to excess. Certain achers attempted to exclude the mother tongue entirely from ie classroom; others devoted an inordinate time to phonetics conversation on pictures, and exalted the oral side as the goal all teaching. Others again neglected the grammar or inter-eted their new-won liberty as a right to teach as they pleased, respective of their colleagues. To-day, while phonetics (*q.v.*) ive been generally accepted in England (though not in France), is seen that the extent of their use (apart from the chart) may left to the choice of the teacher. Again, new grammar points iould be learnt inductively, but the grammar must be systemised and codified. With most pupils grammatical points are iore safely explained in English. Due co-ordination of method in usually be secured by the appointment of a head of depart-ient. Translation from or into the foreign language is often egun two years before the final examination and not often irlier. As regards the exclusion of the mother tongue, we may ike it as an axiom that the cleverer the child the more direct ie teaching. Hence with the duller child the aim should robably be to concentrate rather on reading and translation ian on composition (free or otherwise). At the extreme end of ie scale there are, in the opinion of some experts, a few non-nguistic pupils who would be more profitably engaged in con-ning themselves to the mother tongue.

It is probable that the earlier reformers laid insufficient stress n the rapid acquisition of vocabulary, possibly from their dread f rote-work. To-day there is a fruitful tendency to learn by eart, not merely poems but duly prepared prose passages, a ractice that is at the back of much of the mastery attained by ie French in their own language. Of course such passages need casional revision. Again, the principle of private reading, hich has made such strides in English, has been promoted by ie formation of class and school libraries, and the practice is been further fostered by the introduction of free study eriods in certain schools. Such are the main features of the aching in English secondary schools, up to the first school xamination.

In the central schools, which often prepare their fifth-year upils for similar examinations, the methods are largely the ime, except that in the first year the classes, which are larger, re sometimes divided for conversation, with excellent results. n the advanced courses of the secondary schools, the methods f reading and *lecture expliquée* without translation are largely ollowed, and essays on literature are written in the foreign inguage. A burning point is that the universities which con-uct the higher certificate examinations appear to prefer an-wers in English in the literature papers. A possible solution ould be the award of extra marks for one question to be an-wered in the foreign tongue. In the evening schools methods ave been modernised, but the need of covering the ground more uickly necessarily limits the employment of the more leisurely ractices of the direct method. (C. Bre.)

In the United States

The attempt to make general the employment of the "di-ect method" in the teaching of the foreign modern languages the United States had begun to subside before 1909, when it ecame clear that the method was looked on askance in the best igh schools and preparatory schools, and especially in the col-eges and universities. Many teachers were well acquainted ith foreign languages by ancestry and study abroad; but some ould not speak such languages with ease. Also, the increasing esire for travel in Europe, now so manifest, was only beginning to develop. In the universities and colleges, the professors laughed the method out of court. An anecdote is told about a professor of French in a certain university, who, when asked if he spoke French, answered: "I don't speak French, I teach it." When we consider, however, that at present no teacher of French in the United States would answer in this way, we see that the agitation over the direct method has borne fruit. Indeed, nearly all the text-books in modern languages bear an imprint, however faint, of the direct method, whose influence has been beneficial. It is true, furthermore, that the War gave a strong and perhaps lasting impulse to the study of the spoken language. It is said that when the United States entered the War, the accredited newspaper reporters sent to Europe were remarkable in only one regard: their inability to say the slightest thing in French. This would no longer be the case.

Much of the improvement in the teaching of the modern languages came from another source: the introduction of Phonetics. This study made its way under two forms: formal or theoretical Phonetics and experimental Phonetics. The first came from both France and Germany, as well as from the English school of Bell and Sweet; the latter came from France. The French influence was seen in the steady extension through the universities and high schools of the International Phonetic Alphabet, which is now the only one used in teaching the foreign spoken languages. This alphabet was contrived by Paul Passy (who took hints from Ellis, Bell, Sweet and others) and commenced to be known in the early 'nineties. Its use has become so general that it forms the basis of instruction in diction, music and phonetics, as is seen in the brilliant work being done in New York by such teachers and authors as Adele Baldwin, Marguerite DeWitt, May Laird-Brown and William Tilly.

Experimental Phonetics came from the indefatigable zeal of its founder, the Abbé Rousselot, whose laboratory at first was in the Institut Catholique, Paris, then in the Collège de France. Two or three Americans had begun experimental research at about the same time as Rousselot, but they did not have laboratories at their disposal. None the less, their example prepared the way for the introduction of Rousselot's methods, which have left a permanent impress on the teaching of the modern languages in the United States.

The War favoured the extension of French. Combined reports from about 76% of the elementary schools, public and private, and the high schools and academies and from about 89% of the colleges and universities indicate an enrolment during the year 1923-4 of 629,000 students of French, 392,000 of Spanish, and 65,000 of German. (R. We.*)

FORESTRY (*see* 10.645).—No summary of the timber resources of the world can be described in any sense as accurate or reliable. The facts available are insufficient, the statistics on which estimates are based are often incomparable and even the sources of information are not always above suspicion; overstatements by government departments to attract capital or to justify increased exploitation are as common as understatements by foresters or traders to insure conservation of resources or enhanced prices.

The British Empire contains not less than 1,100 million acres of woodlands, but has under 1,100 forest officers—that is to say, taking the Empire as a whole, less than an average of one forest officer for every 1,000,000 acres. Brazil with 1,000 million acres of tropical and semi-tropical forests has in the European sense no organised forest service at all. The information about the Russian forests, said to be 1,200 to 1,500 million acres in extent, even before the War, was unsatisfactory, especially as regards the virgin softwood forests in Asia and northern Europe. Since the War little authoritative information is obtainable, and such information as there is, is, therefore, for the most part, too old to be of any real utility.

The World's Timber Resources

For purposes of comparison the timber resources of the world may be divided into hardwoods and softwoods, the former being, generally speaking, broad-leaved and, in the temperate zone, deciduous trees; the latter coniferous and non-deciduous. The hardwoods themselves fall naturally into two classes—hardwoods of the temperate zone, some 1,200 million acres in extent, and tropical hardwoods, estimated at 3,600 million acres. The softwoods of the world cover a much smaller area, just over 2,500 million acres. These forests, with the exception of the Paraná pine forests of Brazil, Chile, India and Australasia, are situated in the Northern Hemisphere, over 80% of the total being found between the 45th and 70th parallel north. The more important commercial timbers of the world, the softwoods and temperate hardwoods (calculated on an acreage basis), are situated to the extent of 95% and 89% respectively in the Northern Hemisphere, where 75% of the population exists. While, as a means of estimating timber resources, a calculation by acreage is unsatisfactory, the stand of timber to the acre varying with species, soil and climatic conditions, no unit of measurement can be given which more accurately gives a picture of forest wealth.

Only about 10 to 15% of the world's forests are worked under systematic management, and about these forests alone is reliable information available as to stocks, annual growth, fellings or losses by pests, etc. Of the other forests, 15 to 20% may be classed as commercial forests either in process of exploitation or about to be exploited. About these forests some general trade information is usually available. The balance 65 to 75%, is virgin forest not utilised for commercial purposes, and about which information is non-existent or unreliable. The estimates of acreage have, in the main, been taken from the work of Messrs. Zon and Sparhawk entitled *Forest Resources of the World*. These two distinguished members of the United States Forest Service have succeeded in making a more or less coherent picture of the available data about the forests of the world, supplemented by personal investigations and inquiry where full information was not previously available.

HARDWOOD SUPPLIES

The hardwood timber supply of the world need give little real cause for anxiety. There will be in the future, as in the past, shortages of supplies of individual species. The hardwood forests, however, are so vast in extent, and include so many different types of timber, that the increase of information about recently developed countries, and the advance in the science of timber testing, seasoning and wood technology, should make the substitution of new species for old a more simple and certain proceeding than has formerly been the case. The solution of the hardwood supply question would therefore appear to lie not only in the conservation of existing resources, but also in the ordered investigation of new sources of supply, together with the initiation of such steps as are necessary to make such supplies available as and when they are found in quantities that make their exploitation commercially possible.

United States.—The United States has taken the lead in this matter. Owing to the wholesale clearances of their more accessible hardwood forests by uncontrolled felling, and the almost complete destruction of their valuable chestnut forests by the chestnut bark disease (*Endothia parasitica*), the Federal U.S. Department of Agriculture has for some time been inquiring through its Forest Products Laboratory, Madison, Wis., about the potential supplies of hardwood timber outside the States. Important results have already been obtained in Central and South America.

British Empire.—Inside the British Empire equally good work has been and is being done; at Dehra Dūn in India, at Montreal in Canada and in England under the aegis of the Forest Products Research Board, at Kew, as well as at the Imperial Institute, timbers are being tested and new species identified. In this section of Imperial development it is necessary to insist on one point that has been passed over, viz., that it is not only necessary to educate and indeed to persuade the consumer by scientific and practical tests of the possibilities of a given substitute species, it is also necessary to prove to the satisfaction of wood merchants that that substitute is available on a commercial scale and that the forests in which it is found are suitably situated for exploitation. An Imperial Forestry Bureau advocated by two consecutive Imperial Forestry Conferences is a necessary link between the consumer and the merchant on the one hand, and the systematic botanist, the timber testing centre and the producing units of the Empire overseas on the other.

SOFTWOOD SUPPLIES

The future supply of softwood timber is disquieting, the most unsatisfactory feature being the rapidity with which the accessible virgin forests are being destroyed. In the more progressive and industrially developed countries timber, other than firewood, is used in the proportion of 80% of softwood to 20% of hardwood. Great Britain, the greatest importing country in the world, brings in softwood in the proportion of nine to one hardwood. According to the latest figure available, Finland and Siberia are the only two "net" exporting countries in the world where the resources of softwood timber are not being reduced by annual felling at a greater rate than is made good by annual growth.

United States.—The United States, which consumes nearly one-half the converted timber of the world, is using up its softwood timber reserves at about four times their rate of growth. Only 137,000,000 ac. of virgin forest remain. These are being felled at the rate of 5,500,000 ac. per annum. The situation has caused such general anxiety that the President himself made the following statement in 1924: "Expressed roughly we have left about 745 billion cu. ft. of timber. From this the annual drain is 25 billion cu. feet. This total drain is most significant when we reflect that towards offsetting it we have an annual growth of only six billion cu. ft., and even in our young forests where this growth is taking place cutting has already outstripped growth. We must face the situation that at this rate we are not far from timber exhaustion."

The course of timber denudation in the United States is interesting. First the New England states, then the Lake states and now the South Atlantic states have been cut out in rapid succession. In the Southern states the departmental report of 1920 states that of the 5,400 mills owning or controlling practically the entire remaining virgin stand in the South, 4,410 mills will be cut out in five years or less, and that a further 800 mills will cut out their timber in the next ten years, *i.e.*, by the end of 1930 or thereabouts.

When this last forest reserve on the eastern freeboard is exhausted, the export trade of softwood timber will be concentrated almost entirely in the Pacific states, distant from the main commercial centres by 2,000 m. of railroad or 4,000 m. by sea. This fact is important from two points of view—(*a*) the price of timber must rise very considerably in the Eastern states, where four-fifths of the population are centred; (*b*) that, consequent on a rise in prices due to the lack of local supplies, sea freight and canal charges, America may come into the European market for construction timber, just as she does to-day into the Canadian and European markets for her pulp-wood. In a statement made by Col. W. B. Greeley, Chief of the United States Forest Service, at the British Empire Forestry Conference in 1923, the virgin softwood forests of the United States at the then rate of destruction would be cut out in 25 years, and after that date the industry would have to depend on "cut-over" woods and the less accessible of the Federal reserves.

Canada.—The position in Canada is but little more satisfactory. According to Mr. Craig, the Canadian statistical officer (report of 1923), the total amount of softwood in Canada amounts to 198,000 million cu. ft., one-half of which can be profitably operated under existing conditions. The amount of softwood used annually for all purposes is about 900,000,000 cu. ft., but owing to the method of exploitation this entails the destruction of 1,700,000,000 cu. ft. of standing timber. In five years the annual loss of merchantable timber from fire had amounted to 790,000,000 cu. ft., and in 10 years destruction by the spruce bud worm had averaged 1,300,000,000 cu. feet. Other insects and forest diseases have also caused serious loss in the forest, so that the annual drain on the resources of the Dominion is probably ot less than 4,000,000,000 cu. feet. At this rate the accessible ands of virgin forest would last 25 years.

Europe.—In Europe the softwood position is by no means tisfactory. The demand of industrial life for an adequate mber supply increases in volume much more quickly than the owth of the population, yet there is no margin for increased oduction outside Russia, and the estimates of Russian reserves e founded on quite insufficient data.

Three of the principal softwood exporting countries in Europe e Norway, Sweden and Finland. Norway has been living on her rest capital for many years, and her softwood timber con-umption exceeds growth by about 51,000,000 cu. feet. Sweden ntil recently was supposed to be living well within her forest eans. A recent survey has shown that the annual growth, pecially in the north, is less than was previously calculated, and nsumption exceeds growth by 100,000,000 cu. feet. Finland is ported to be using 140,000,000 cu. ft., less than the annual owth. Two facts must be borne in mind—(*a*) that her calcula-on of annual growth will probably have to be revised, (*b*) that e extension of her saw-milling industry is rapid.

Russia.—To what extent the virgin forests of Russia can come the aid of Europe and America is difficult to estimate. Apart om political questions there are certain limiting factors which e bound to affect continuous production.

1. The main group of softwood forests is situated north of the th parallel. The rate of growth is necessarily slow; on the Finnish d Swedish analogy, probably not more than 20 cu. ft. per ac. per num. In the extreme north the rate of growth is probably only lf that rate, while owing to the infrequency of seed years restocking ust necessarily be a slow process.

2. The extent of land over which Russian forests are spread is so eat and the communications so poor that only a relatively small rtion is accessible under existing conditions and at present day mber prices.

Mr. Fraser Story in his review of the softwood resources of urope estimates that 90,000,000 ac. of the Russian forests are erchantable as opposed to 243,000,000 ac. unmerchantable. e includes as unmerchantable all woods in which the cost of traction is prohibitive, or on which the land is so poorly ocked or the timber of such a character of growth as to be un-itable for commercial use. The merchantable area includes the eas which before the War could have been exploited without due commercial risk with the means of extraction and utilisa-on then available.

3. Russia has a population nearly as large as the United States. e is already an importer of timber in her southern states. Her nsumption of hardwoods and softwoods before the War was cal-lated at only 66 cu. ft. per capita per annum. It is not improbable at with the relaxation of forest regulations her per capita consump-on has materially increased and may approach that of Norway and weden, 130 cu. ft. per annum.

4. It is calculated that before the War Russia was living on her pital, *i.e.*, that her consumption exceeded her annual growth by 851 million cu. ft. per annum.

Siberia.—The productive Russian forests in Asia probably mount to 500 to 600,000,000 acres. Only one-fifth of this area s ever been surveyed. The Pacific slopes and the forests ibutary to the Amur and other small coastal rivers are the only eas capable of exploitation under existing trade conditions, d may amount to 40,000,000 acres of softwood and hardwood rests, only one-tenth of which has been surveyed. The main pplies of Central Siberia will only be available when political nditions are such as to permit of the investment of capital, e creation of railways and the establishment of banks and edit institutions. Even in the more easily developed area an port trade will have to be built up from its very foundations. efore the War there were said to be only 74 producing saw-ills in Siberia; since the War exports of timber to Japan and hina have increased; but even to-day, considering the size the country, they are relatively unimportant.

Other Areas.—The remaining virgin softwood forests of the orld can be dismissed in a very few words. In Japan consump-on is rapidly overtaking production. Japan has for long been axious about future supplies, and has embarked on the largest planting programme of any country in the world. The recent survey by the United States Forest Service in Alaska has proved disappointing. While the hinterland contains important reserves of pulp wood, the milling timber is confined to a strip of land on the coast averaging, it is said, only a few miles in width. Australia and New Zealand, despite their softwood supplies, are importing countries. The Paraná pine forests of Brazil, once considered as an important timber reserve for the southern hemisphere, are being rapidly cut out and no system of reforestation has yet been adopted.

Conclusion.—It would appear that while information about the softwood forests of the world leaves much to be desired, there are sufficient data to warrant certain conclusions:—

1. That except in Russia—an unknown quantity—the main softwood virgin timber reserves will be exhausted before very long, and producers will have to depend more and more on "cut-over" forests or woods raised or restocked by the agency of man.

2. That the United States shortage is likely to come more quickly than the European one.

3. That the more the American supply becomes centred in the Pacific Coast States the greater is the probability of the industrial States of North-eastern America coming into the European market for saw-timber in the same way as they do now for pulp of wood.

4. That as the United States consumes 13,750 million cu. ft. of softwoods as opposed to a total European consumption of 9,120 million cu. ft., the United States advent into European markets will have an important bearing on European prices.

FORMOSA (*see* 10.669).—The island of Formosa (Taiwan) has an area of 13,839 sq. m. and on Oct. 1 1920 the population was 3,655,308, representing a density per sq. m. of 264 inhabitants. The population was estimated at 3,758,900 on Oct. 1 1923. The chief towns are Taihoku, Tainan, Kagi and Taichu. The Hokoto Is. (Pescadores) are included in Taiwan.

Administration and Finance.—Taiwan was placed under a civil administration in April 1896, and legislative steps were taken in the following year to put the finances of the island on an independent footing. Meanwhile a grant was made from the Imperial Treasury, but the subvention was withdrawn in 1906 owing to the satisfactory financial condition of the island. Furthermore, with the development of its industry and the increase of various public establishments, finance was greatly expanded and the total revenue and expenditure in the Budget for 1924–5 are put at 91,553,193 yen (excluding the extraordinary budget).

Government Monopolies.—The Government monopoly undertakings on the island are opium, salt, camphor and tobacco, the importation of opium and the manufacture and smoking of the drug being strictly prohibited since 1896, except by licence in the case of confirmed smokers. The number of licensed smokers had decreased from 117,000 in 1900 to 38,673 at the end of 1923.

In May 1899 the Government took steps to improve the quality and increase the quantity of salt produced, which had hitherto suffered from the fluctuations due to irregular and sporadic private enterprise. The total area of the salt-fields is now over 2,348 kō (about 4,500 ac.); the quality of the salt has decidedly improved, and the annual output has been steadily increasing, having risen to 404,090,000 kin (242,400 metric tons) in 1923, sufficient to satisfy local requirements and also for export to Japan, Chosen, Karafuto, etc. In 1899 the production of camphor was also controlled, and in 1905 the monopoly system was extended to Taiwan-cut tobacco, in both cases with beneficial results.

Trade.—The chief commodities exported from Taiwan are tea, rice, sugar, camphor, turmeric, flax, hemp, jute and coal. Foreign trade, consisting of oversea trade and trade with the homeland (Japan proper), has grown year by year. The development of Taiwan trade with foreign countries was affected adversely by the duties which have been increased frequently since the revision of customs tariffs in 1899, but its trade with the homeland has made steady progress with the development of various industries, stimulated by the growing perfection of banking and communication facilities in the island.

In 1907 the volume of trade with Japan and overseas trade was 58,340,000 yen, while in 1910 it was 108,880,000 yen (largely owing to the development of the sugar industry). In 1923 the total trade reached 308,720,000 yen. Of this the exports to foreign countries were valued at 29,150,000 yen, and the exports to Japan proper at 169,440,000 yen, a total of 198,590,000 yen. The imports amounted to 39,110,000 yen from foreign countries, and 71,010,000 yen from the homeland, totalling 110,120,000 yen. Thus the excess of total exports over total imports for 1923 amounted to 88,460,000 yen.

Agriculture and Industry.—Almost the whole of Taiwan is a rice-growing country, yielding two crops a year. In 1923 the rice crops amounted to 4,866,087 koku (24,102,639 bu.), though in that year they suffered from the worst drought ever known. The oolong and souchong teas, produced in the north of the island, are important exports to foreign countries; the value of the oolong exported abroad in 1923 was 5,160,965 yen.

The sugar industry enjoyed great prosperity in 1916 and 1917, the value of exports being 11,317,643 yen and 15,775,205 yen respectively. The area under sugar-cane cultivation in 1923 was 114,710 kō (1 kō = 2·45 ac.) which, owing to the satisfactory growth of the plant, yielded raw sugar amounting to 6,192,040,773 kin (1 kin = 1·323 lb.). There were operating 44 plants of the latest style with a capacity of 34,650 English tons, 11 improved-style factories with a capacity of 820 English tons and 101 old-style factories, which altogether produced 521,501,144 kin of centrifugals, 59,878,831 kin of refined sugar and 10,860,026 kin of brown sugar, aggregating 592,240,001 kin.

Gold, alluvial gold, silver, copper, coal, petroleum and sulphur are all found in the northern part of the island. The total value of mineral products in 1923 was 12,915,908 yen, being an increase of a little over 210% over the 1913 figure. The gold produced in 1923 was 411,649 grammes; placer gold, 8,306 grammes; silver, 569,576 grammes; coal, 1,445,000 metric tons; and petroleum, 25,289 hectolitres.

The fishing industry of Taiwan owes much of its present prosperity to Government encouragement, although owing to the favourable ocean currents, fishing can be carried on all around the island. Artificial rearing of oysters, prawns, carp, etc., is accomplished both in salt and brackish waters, and it is a characteristic of the Formosan fisheries that whilst the natural produce is valued at about 4,000,000 yen, the value of the products of fish culture is 2,000,000 yen.

Banking.—The Bank of Taiwan (est. 1897) is the central bank of the island, and has an authorised capital of 45,000,000 yen and a paid-up capital of 39,375,000 yen. The bank is empowered to issue bank-notes, and to transact ordinary banking and foreign exchange business. There are several ordinary banks and many credit associations.

A great increase in the business of the Post-Office Savings Bank took place during 1910–23, the number of depositors having risen from 90,893 in 1909–10 to 457,869 in 1922–3, the deposits increasing from 1,900,700 yen to 8,171,201 yen.

In 1899 the Government commenced planning out a trunk line from north to south of the island, connecting the ports of Keelung and Taku and passing through Taihoku, Taichu and Tainan. Branch lines, further opening up the rice, sugar, tea and mining districts, were gradually completed, so that at the end of the financial year 1922–3 there were 468·70 m. of railway open to traffic. In the same year over 13,000,000 passengers and more than 3,000,000 tons of goods were carried, the receipts being over 12,000,000 yen. In addition to the state railways, there were at the end of 1922 1,242 m. of railway belonging principally to sugar factories and 547 m. of track for hand-propelled cars, an important means of local transport peculiar to the island. (H. SA.; K. M.)

FORREST, JOHN FORREST, 1ST BARON (1847–1918), Australian statesman and explorer (*see* 10.672), was acting premier of Australia in 1907 during the absence of Mr. Deakin in London. He took office again as treasurer in Mr. Hughes's "National" Cabinet of 1917, but resigned owing to ill-health early in 1918, when he was raised to the peerage, being the first Australian to be so honoured. He died at sea on his way to London to take his seat in the House of Lords, Sept. 3 1918.

FORSTER, EDWARD MORGAN (1879–), British novelist, was educated at Tonbridge School and King's College, Cambridge. His first novel, *Where Angels Fear to Tread* (1905) was followed by *The Longest Journey* (1907) and *A Room with a View* (1908). Wider attention was won by *Howards End* (1910), but thereafter, except for some short stories, *The Celestial Omnibus* (1911), he published little until 1924, when *A Passage to India* appeared. This was a fruit of first hand observation of modern Indian life and with it Forster entered into a fuller public recognition of his powers as a writer with a gift for keen analysis of social character and relationships. Wartime work in Egypt enabled him to write a useful book on *Alexandria: A History and a Guide* (1922), from which came the material for the short studies of Alexandrian history, ancient and modern, in *Pharos and Pharillon* (1923).

FORSYTH, PETER TAYLOR (1848–1921), British Nonconformist divine (*see* 10.677), died in London Nov. 11 1921. Among his later works were *The Person and Place of Christ* (1909); *The Principle of Authority* (1912) and *This Life and the Next* (1918).

FORTIFICATION: *see* SIEGECRAFT.

FORT WORTH, Tex., U.S.A. (*see* 10.728), entered on a period of rapid development after the establishment of Camp Bowie (1917) and three flying fields for the training of Canadian and American aviators, and the erection (1918) of the army and navy helium plant. With the discovery of the Ranger and Burkburnett and other important new oilfields, it became the geographical centre of the oil-producing region of the southwest, and by 1925 was the greatest petroleum pipe-line centre in the world. Its refineries had a daily crude capacity of 75,000 barrels. Natural gas was brought in from 15 fields. Beginning about 1920, the transition in western Texas from ranching to stock-farming and diversified agriculture (especially cotton, wheat and feed crops) added a large and prosperous population to Fort Worth's trading territory, supplied raw materials for new industries, stimulated meat-packing and flour-and-feed-mills and enlarged its grain and livestock markets. A textile mill was established in 1924; a cement plant in 1925. Bank deposits were $15,425,000 in 1910; $78,540,000 in 1925. The value of manufactured products was $8,661,000 in 1909; $38,160,000 in 1919; $75,163,236 in 1923. In 1922 the area of the city was more than doubled by the annexation of 22 sq. m., including Niles Polytechnic, and a large suburban territory. The population in 1920 was 106,482, of whom 15,896 were negroes and 7,50 foreign-born; in 1925, 185,000 according to a local estimate, taking into account the suburban territory annexed in 1922.

A new charter, adopted in April 1925, established the Council manager form of government and created a city plan board. Plans were under way (1925) for the construction of a Union passenger station and an interchange belt railway, and for a great project of water conservation, flood control and irrigation by Tarrant County Water Improvement District Number 1. The leading educational institutions include Texas Christian University, Southwestern Baptist Theological Seminary and Texas Woman's College, established in 1914, with which the older Polytechnic College was merged.

FOSDICK, HARRY EMERSON (1878–), American divine, was born at Buffalo, N.Y., May 24 1878. He graduated from Colgate University in 1900, proceeding thence to Union Theological Seminary, New York City. Ordained into the Baptist ministry in 1903, he was pastor of the First Baptist Church, Montclair, N.J., 1904–15. He rapidly acquired a high reputation as a preacher, especially among the universities. Becoming instructor in homiletics at Union Theological Seminary in 1908, he was appointed Morris K. Jesup professor of practical theology in 1915. In 1918 the First Presbyterian Church of New York City was founded by amalgamation of The Old First, Madison Square and University Place churches, and Dr. Fosdick became its associate minister and permanent preacher Dec. 29 1918.

On May 21 1922 he preached a sermon entitled "Shall the Fundamentalists Win?" making a wide plea for tolerance in religion and asking that the door of Christian fellowship be left open to all who sincerely desired to follow Christ, regardless of specific credal belief. The Presbytery of Philadelphia formally brought the matter of Dr. Fosdick's teaching before the General Assembly of the Presbyterian Church at Indianapolis in 1923, stigmatising it as heretical and demanding action. The New ork Presbytery, acting on the request of the Assembly, apointed an investigating committee which reported to the Genral Assembly of 1924 that they found Dr. Fosdick's teaching nd preaching to be in accordance with Presbyterian standrds. This report was vehemently attacked by the Fundamenalist element in the Assembly and was referred to the Judicial Commission of the church, which, after hearing evidence, deided that Dr. Fosdick must take the vows of a Presbyterian minister (implying acceptance of the Westminster Confession) r vacate his pulpit. He thereupon tendered his resignation, ct. 6 1924, which was accepted and took effect March 1 1925. mmediately thereafter the Park Avenue Baptist Church of New York called Dr. Fosdick to its pastorate, agreeing to open s membership to all Christians without insisting on its tradional ordinance of baptism and also to remove from its present te and build an amply equipped church on Morningside Heights—the educational centre of the city.

His works include *The Second Mile* (1909); *The Manhood of the Master* (1913); *The Assurance of Immortality* (1913); *The Meaning f Prayer* (1915); *The Challenge of the Present Crisis* (1917); *The Meaning of Faith* (1918); *The Meaning of Service* (1920); *Christianity nd Progress* (1922); *The Modern Use of the Bible* (Yale lectures, 1924).

FOSTER, SIR GEORGE EULAS (1847–), Canadian statesman, was born in New Brunswick Sept. 3 1847. Educated in New Brunswick, Edinburgh and Heidelberg, he took up teaching in Canada. In 1882 he became Conservative member in the Canadian Parliament, representing New Brunswick, and in 885 became Minister of Marine and Fisheries. From 1888–1896 e was Minister of Finance. In the Borden Administration of 911 he was Minister of Trade and Commerce, retaining the ortfolio in the Union Govt. of 1917. In 1917 Foster was summoned to the Senate of Canada. He was a great advocate of referential trade within the Empire, and in 1903 he made a eries of speeches in England in support of Mr. Chamberlain's olicy. Sworn of the Imperial Privy Council in 1916, he was n the same year appointed one of Great Britain's four repreentatives at the Economic Conference at Paris. In 1918 Foser was created K.C.M.G., and he represented Canada at the Peace Conference, 1919, and at the first assembly of the League f Nations in 1921. He was later elected a vice-president of the ssembly.

FOUILLÉE, ALFRED JULES ÉMILE (1838–1912), French hilosopher (*see* 10.737 and 18.250), died at Lyons July 16 1912.

FOURTEEN POINTS, THE.—During the winter of 1917–8 talk f peace was prevalent throughout the world. Between Russia nd Germany actual peace negotiations were in progress during he opening months of 1918; and on Jan. 5 1918 the British Premier outlined the terms upon which Great Britain and her Allies ould be prepared to negotiate for peace.

On Jan. 8, three days after Lloyd George's speech, President Woodrow Wilson, in his address to the joint session of Congress, ormulated under 14 separate heads his ideas as to the essential ature of a post-War settlement. Before the delivery of his adress he had received from a committee of inquiry, set up by Col. House in Sept. 1917, a report upon the territorial settlement that hould follow the conclusion of the War. It has been stated that o fewer than six, and these the territorial points, of Wilson's Fourteen Points were "directly framed" upon the recommendations contained in the report. It has also been stated that he report was drawn up by Dr. S. Mezes, D. H. Miller, and Walter Lippmann.[1]

In any consideration of the Fourteen Points it must be borne n mind that in drafting the Points, especially the first five, egard was had not merely to the future, but also to the fact that hey could be used as a diplomatic weapon in the present.[2] In rafting Point 4 the President was probably inspired by the exmple of the United States, where each State has only a militia or the preservation of internal order; the safety of all from external attack being guarded by the Federal Army.

The Fourteen Points were:—

1. Open covenants of peace openly arrived at, after which there shall be no private international understandings of any kind, but diplomacy shall proceed always frankly and in the public view.
2. Absolute freedom of navigation upon the seas outside territorial waters alike in peace and in war, except as the seas may be closed in whole or in part by international action for the enforcement of international covenants.
3. The removal, so far as possible, of all economic barriers and the establishment of an equality of trade conditions among all the nations consenting to the peace and associating themselves for its maintenance.
4. Adequate guarantees given and taken that national armaments will be reduced to the lowest point consistent with domestic safety.
5. A free, open-minded and absolutely impartial adjustment of all colonial claims based upon a strict observance of the principle that in determining all such questions of sovereignty the interests of the populations concerned must have equal weight with the equitable claims of the Government whose title is to be determined.
6. The evacuation of all Russian territory, and such a settlement of all questions affecting Russia as will secure the best and freest co-operation of the other nations of the world in obtaining for her an unhampered and unembarrassed opportunity for the independent determination of her own political development and national policy, and assure her of a sincere welcome into the society of free nations under institutions of her own choosing, and more than a welcome, assistance also of every kind that she may need and may herself desire. The treatment accorded Russia by her sister nations in the months to come will be the acid test of their goodwill, of their comprehension of her needs as distinguished from their own interests, and of their intelligent and unselfish sympathy.
7. Belgium, the whole world will agree, must be evacuated and restored without any attempt to limit the sovereignty which she enjoys in common with all other free nations. No other single act will serve as this will serve to restore confidence among the nations in the laws which they have themselves set and determined for the government of their relations with one another. Without this healing act the whole structure and validity of international law is forever impaired.
8. All French territory should be freed, and the invaded portions restored, and the wrong done to France by Prussia in 1871 in the matter of Alsace-Lorraine, which has unsettled the peace of the world for nearly 50 years, should be righted in order that peace may once more be made secure in the interest of all.
9. A readjustment of the frontiers of Italy should be effected along clearly recognisable lines of nationality.
10. The peoples of Austria-Hungary, whose place among the nations we wish to see safeguarded and assured, should be accorded the freest opportunity of autonomous development.
11. Rumania, Serbia and Montenegro should be evacuated, occupied territories restored, Serbia accorded free and secure access to the sea, and the relations of the several Balkan States to one another determined by friendly counsel along historically established lines of allegiance and nationality, and international guarantees of the political and economic independence and territorial integrity of the several Balkan States should be entered into.
12. The Turkish portions of the present Ottoman Empire should be assured a secure sovereignty, but the other nationalities which are now under Turkish rule should be assured an undoubted security of life and an absolutely unmolested opportunity of autonomous development, and the Dardanelles should be permanently opened as a free passage to the ships and commerce of all nations under international guarantees.
13. An independent Polish State should be erected which should include the territories inhabited by indisputably Polish populations, which should be assured a free and secure access to the sea, and whose political and economic independence and territorial integrity should be guaranteed by international covenant.
14. A general association of nations must be formed under specific covenants for the purpose of affording mutual guarantees of political independence and territorial integrity to great and small States alike.

President Wilson developed his theories during 1918 in a series of speeches, to which reference was subsequently made during the Armistice negotiations. These are as follows:—

The Four Principles.—In the "Four Principles" speech in Congress, Feb. 11 1918, he declared:—

1. That each part of the final settlement must be based upon the essential justice of that particular case and upon such adjustments as are most likely to bring a peace that will be permanent;
2. That peoples and provinces are not to be bartered about from sovereignty to sovereignty as if they were chattels or pawns in a game, even the great game, now forever discredited, of the balance of power; but that
3. Every territorial settlement involved in this War must be made in the interest and for the benefit of the populations concerned, and not as a part of any mere adjustment or compromise of claims amongst rival States; and

---

[1] R. S. Baker, *Woodrow Wilson*, vol. 1, pp. 110–1.
[2] C. Seymour, *Woodrow Wilson*, pp. 235 *seq.*

> 4. That all well-defined national aspirations shall be accorded the utmost satisfaction that can be accorded them without introducing new or perpetuating old elements of discord and antagonism that would be likely in time to break the peace of Europe, and consequently of the world.

The Four Ends.—In the " Four Ends " speech of July 4 1918 occurs the following passage:—

> These are the ends for which the associated peoples of the world are fighting and which must be conceded them before there can be peace:—
>
> 1. The destruction of every arbitrary power anywhere that can separately, secretly, and of its single choice disturb the peace of the world, or, if it cannot be presently destroyed, at the least its reduction to virtual impotence.
>
> 2. The settlement of every question, whether of territory or sovereighty, of economic arrangement, or of political relationship, upon the basis of the free acceptance of that settlement by the people immediately concerned, and not upon the basis of the material interest or advantage of any other nation or people which may desire a different settlement for the sake of its own exterior influence or mastery.
>
> 3. The consent of all nations to be governed in their conduct towards each other by the same principles of honour and of respect for the common law of civilised society that govern the individual citizens of all modern States, and in their relations with one another, to the end that all promises and covenants may be sacredly observed, no private plots or conspiracies hatched, no selfish injuries wrought with impunity, and a mutual trust established upon the handsome foundation of a mutual respect for right.
>
> 4. The establishment of an organisation of peace which shall make it certain that the combined power of free nations will check every invasion of right and serve to make peace and justice the more secure by affording a definite tribunal of opinion to which all must submit and by which every international readjustment that cannot be amicably agreed upon by the peoples directly concerned shall be sanctioned. These great objects can be put into a single sentence. *What we seek is the reign of law, based upon the consent of the governed and sustained by the organised opinion of mankind.*

The Five Particulars.—The " Five Particulars " (speech of Sept. 27 1918) were:—

> 1. The impartial justice meted out must involve no discrimination between those to whom we wish to be just and those to whom we do not wish to be just. It must be a justice that plays no favourites and knows no standards but the equal rights of the several peoples concerned.
>
> 2. No special or separate interest of any single nation or any group of nations can be made the basis of any part of the settlement which is not consistent with the common interest of all.
>
> 3. There can be no leagues or alliances or special covenants and understandings within the general and common family of the League of Nations.
>
> 4. And, more specifically, there can be no special selfish economic combinations within the League and no employment of any form of economic boycott or exclusion, except as the power of economic penalty, by exclusion from the markets of the world, may be vested in the League of Nations itself as a means of discipline and control.
>
> 5. All international agreements and treaties of every kind must be made known in their entirety to the rest of the world. Special alliances and economic rivalries and hostilities have been the prolific source in the modern world of the plans and passions that produce war. It would be an insincere as well as an insecure peace that did not exclude them in definite and binding terms. (*See* also EUROPE.)

BIBLIOGRAPHY.—The text of the Fourteen Points will be found in C. Seymour, *Woodrow Wilson and The World War*, vol. 3, pp. 42–5 (1921). See also R. S. Baker, *Woodrow Wilson and World Settlement*, 3 vol. (1923); H. W. V. Temperley, *History of the Peace Conference of Paris*, vol. 1, pp. 431–5 (London, 1920).

FOX-HUNTING (*see* 13.947).—The years immediately preceding the World War were in many ways the Golden Age of this great English sport. Money was plentiful and it was noticeable that newcomers to the country-side were inclined to favour hunting rather than shooting. Increased facilities for transport enabled people to hunt from towns. Horse-breeding and hound-breeding had been placed on a sound basis, and hunting, generally, had been organised and stabilised under the supreme authority of the Masters of Foxhounds Association.

War Difficulties.—Then came the War. The drain on horses was tremendous; subscription lists dropped to practically nothing; and, worst of all, at the height of the submarine menace, the feeding of hounds became an almost insoluble problem. The expense was enormous and there was a considerable outcry to the effect that hounds should be suppressed altogether as useless animals which consumed useful food. In 1917–8 hunting very nearly ceased altogether, and had it once come to an end it is extremely improbable that it would ever have been revived. The Association of M. F. H., however, in collaboration with Sir William Buxton, tackled the problem. All over the country the number of hounds was reduced, the reduction being effected partly by killing off hounds, but mainly by drafting large numbers out of the country, notably to America, and by breeding fewer.

These drastic measures had their reward. Not only was hunting saved, but it was far easier for the staffs, greatly depleted by the War, to deal efficiently with these reduced packs. Further, half a century of hound shows had given the general breeder a very sound idea at what to aim; so that, in spite of these reductions, not only was the total number of hounds in England in 1925 very nearly up to the pre-War strength, but the quality of English hounds was as high as ever. Not a single well-known hunt ceased to exist. In 1926 there were over 200 packs of foxhounds in the British Is. and 86 in the United States and the British Dominions.

Post-War Developments.—The end of the War by no means put an end to the difficulties which faced hunting. Judicious reductions, compensated for by breeding on sound lines, settled the hound difficulty. The question of horses largely answered itself by the release of an enormous number of animals from the army. After the War, too, whether as a direct result or not it is impossible to say, there was a decided improvement in the quality of the horses; this has been accentuated by the judgments given at horse shows. Before the War the showing animal and the hunter were two distinct types; the animal that won prizes was not likely to prove of much use across country and vice versa. But after the War the show animal was displaced by the real hunter, who is quite capable of winning a prize in the show ring in the summer and a point-to-point in the spring, the ideal at which to aim. The subscriber difficulty was also automatically solved by the return of the armies and, at any rate immediately after the Armistice, there were more people hunting than before the War.

Speaking generally, then, fox-hunting recovered in a surprising way from the direct consequences of the War. But an indirect consequence still had a great and adverse effect on the sport, namely, the change in the social and territorial conditions of rural England. This began before 1914, but was enormously accentuated by the War. In the old days rural England was largely in the hands of the great landowners, who were probably hunting men themselves, or at any rate supporters of hunting, and their tenant farmers, who took their cue from their landlord. Then came the extensive sales of landed property, due to the heavy taxation of the War period and after with its adverse effects on the sport. (C. L. R.)

FRACTURES.—The treatment of fractures has received considerable attention during the 15 years 1910–25, with a corresponding improvement in the general level of results. The development of radiography (*see* RADIOTHERAPY) and its more general application have produced a greater knowledge of the displacements which occur and may remain after a fracture, and a more critical spirit toward the results of these injuries has developed.

Normal Form.—The restoration of the normal form of the broken bone is an important factor if the best result is to be obtained. After the fracture of a long bone of the lower extremity, correctness of alignment is undoubtedly of the greatest importance; in the upper extremity, however, good functional results may be obtained when the position of the bone deviates considerably from the normal. The demand for accurate reposition of fragments has been met by wider use of open operations, whereby replacements of the fragments can be carried out under the eye of the surgeon, and fixation secured by the insertion of metal or bone plates, or suture material. With the precision of modern surgical technique, such intervention is possible without the risk of infection which held back the older surgeons from undertaking such procedures save in exceptional cases.

Function.—The restoration of function in the injured limb after a bone has been broken has received increasing notice. The oblem is recognised as a complicated one, each aspect of which ust receive consideration. Restoration of the normal line of the ne is of the first importance, but the repair of the soft structures erlying the fracture has an equal influence on the final result. oreover, stiffness in joints near the fracture may develop in ses immobilised for too long, and, if persistent, is a source of rious disability. These complications have been avoided or inimised by modified splint treatment, early massage and conolled movements. Various forms of electrical treatment have so been found helpful.

War Experience:—The intensive experience in the treatment of actures afforded by the World War came during the development of methods on the above lines, and yielded a store of imrovements in technique, while it tended to crystallise opinion the relative value of various methods of treatment for the dividual case. The general introduction of splints, which allow action to be made on the injured limb, facilitated the control bone alignment without open operation. Other mechanical nprovements elaborated enable direct traction to be made on one fragments. The transfixion of the bone with pins, and the se of metal calipers to grip the fragments, are examples of such ocedures.

Present Tendency.—In general at the present time the tenency to carry out open operations on all fractures of long bones less in evidence. This is due partly to the advance in methods splintage, but also to the fact that operations of this character, oupled with rigid fixation by means of metal plates, delay the rocess of union, and may be the source of subsequent adhesions etween bones and the subjacent soft structures. In America ere has been a movement to employ slips of the patient's own one for the purpose of fixation at open operations. This produre involves a more elaborate technique, but certainly overomes some of the disadvantages of plating with metal.

Compound or Open Fractures.—The introduction of infection ito a fracture has always been a bugbear of surgeons, as, once ippuration is established in bones, it runs a slow course and is able to lead to sequestration, or death, of some part of the bone, nd slow union. War experience has shown clearly that antiptics are of little value in the disinfection of a lacerated wound. he best method of eradicating infection in connection with ounds of this kind was found to be the excision of the track nd the removal of all contaminated tissues. The application of is process of wound excision or *débridement* to the more severe ypes of compound fracture has greatly improved the results. nce the infection has been avoided or overcome, a compound acture offers no more serious problem in treatment than does a mple one.

Un-united Fractures.—Though delay in the process of union is ommon enough for several reasons, failure of bones to unite rmly in healthy individuals is rare. It is, however, met with in hose cases in which a large part of the bone substance has been estroyed or damaged by the primary injury or subsequent fection. These cases are now treated with a high measure of iccess by bone grafting. Fresh bone taken from the patient imself gives the most reliable results. In cases in which the riginal broken bone ends can actually be brought together, a eef bone and preserved human bone have been employed with ome measure of success. As to the degree to which the grafted one replaces normal bone, the consensus of opinion is that ne graft acts as a scaffold along which new bone grows, rather an that it becomes a part of the host skeleton. At any rate it rms a firm bond about which, under suitable conditions, new one formation takes place. (C. M. P.*)

FRANCE, ANATOLE (1844–1924), French man of letters (*see* .775).—For 30 years French literature was dominated in the yes of all the world by the fame of Anatole France. Although is influence declined in the last period of his life the value of his t was still widely recognised. His ideas were questioned, but ot his style nor the services rendered by him to the language. n his old age he was revered as a genius and a patriarch. No eputation since Voltaire's has been found comparable with his.

The son of a bookseller called Thibault, this youth who was to make illustrious the pseudonym of Anatole France started his career quite humbly. He was fond of literature, he was studious and erudite, but negligently preferred reading to writing. He composed publishers' puffs and contributed a weekly article signed "Gérôme" to the *Univers Illustré.* For his own amusement he wrote verse, *Les poèmes dorés* (1875) and *Les noces Corinthiennes* (1876), which showed learning, charm and taste. In 1879 he published his first volume of stories, *Jocaste et le chat maigre*, and in 1881 his first novel, *Le crime de Sylvestre Bonnard*, which was acclaimed by the discriminating as delightful.

In 1883 he first met Madame Arman de Caillavet, with results that profoundly influenced his career. Mme. de Caillavet became his life-long friend. She was clever and active; she had a host of acquaintances and her receptions were attended by the leading figures of literature and politics. She laboured for the fame of Anatole France, and she forced him out of his inertia into composition. The extracts from her correspondence with him prove the important share she took in his writings, and in the dedication of *Crainquebille* (1904) Anatole France could say: "To Madame de Caillavet, this book which I should not have written without her help, for without her help I should write no books."

For 40 years Anatole France poured out a series of lively, solid, graceful and profound works. There are the pungent and mischievous short stories, *Balthazar* (1889), *L'étui de nacre* (1892), *Le puits de Sainte-Claire* (1895); the meditative and critical books, *Les opinions de Jérôme Coignard* (1893), *La vie littéraire* (4 vol. 1883–92); a philosophical novel, *La rôtisserie de la Reine Pédauque* (1893); an historico-philosophic novel, *Thaïs* (1890), describing Alexandria at the beginning of our era and contrasting the ideals of dying paganism with those of nascent Christianity; an admirable novel on the French Revolution and the Terror, *Les dieux ont soif* (1912); a society novel, *Le lys rouge* (1894), a powerful study of jealousy set amid the artistic treasures and lovely vistas of Florence; then the series of political satires, the four volumes of *L'histoire contemporaine—L'orme du mail* (1897), *Le mannequin d'osier* (1897), *L'anneau d'améthyste* (1899), *M. Bergeret à Paris* (1901), where Anatole France creates the legendary figure of M. Bergeret and portrays society before and during the Dreyfus affair; novels of a revolutionary tendency, *Sur la pierre blanche* (1903), *L'île des Pingouins* (1908), *La révolte des anges* (1914), a biography of Joan of Arc (1909–10); lastly the reminiscences, *Le petit Pierre* (1918), *La vie en fleur* (1922). Such is the sum of this work admirable in its wealth and variety.

The philosophy of Anatole France developed during the course of his career. Until 1900 he was primarily a sceptic. As Voltaire's spiritual son, he delighted in the play of ideas and observed without pity the stupidity and the silliness of men. He probed the past and the present and spared no example of human inconsistency, error or weakness. *Les opinions de Jérôme Coignard* gives the reader much pleasure, so witty and mischievous is the author, and gives him, too, a complete lesson in scepticism. The same remark may be passed on *Les dieux ont soif*, where Anatole France considers almost exclusively the failures of the French Revolution. At this time the author seems to have kept respect for beauty alone, the beauty of natural or artistic forms or of such superior intelligence as was shown in the great Greek and Latin writers. Meanwhile he beamed indulgently upon an imperfect universe. As he believed in nothing, he did not believe in a better or a worse. In the writings prior to 1900 may even be found conservative and aristocratic maxims. A supreme indifference inclined him to accept what is rather than risk what might be.

On the outbreak of the political crisis of 1900, his temper changed. He was then seen to show a preference for the progressive parties, and little by little went on to the revolutionary parties which became honoured by his support. He was no orator; words came slowly, and neither his mind nor his phrases were of the kind likely to be popular. The part taken by him at public meetings was undistinguished, being limited to signing manifestos and applauding resolutions, especially those with an international objective. He was more powerful with his pen. An opponent of Church and State, he seemed to put his faith in the people and to expect the world to be renewed by some kind of revolution. On this point his ideas remained rather vague. In one of his books, *Sur la pierre blanche*, he ends the description of future society with a dreadful cataclysm that destroys everything, and here he is nearer to nihilism than to socialism. The World War changed the trend of his thoughts. As he was too old to serve in the field he wanted at least to show his good will and asked to be employed in a Tours office. This great upheaval left him uncertain concerning the destinies of humanity. Perhaps extreme scepticism is not for long tolerable, and Anatole France felt the need of escape into a revolutionary faith which he refused to define, leaving it a mere aspiration.

What is indisputable is the quality of Anatole France's art. The younger generations, tried by war, and witnessing the consequent political difficulties, ill comprehend the detachment of dilettante M. Bergeret. They need more moral discipline, they believe more in virtue and action. But they do not deny the master who charmed their elders with his graceful wit and magic phrases. As a storyteller, in lucidity of thought and form, Anatole France is incomparable. In his style, too, there is a sweetness, an almost voluptuous grace, which distinguishes his phrases from those of any other writer. He owed much to Voltaire, much to Renan, much to the old French romances, to memoirs and to chronicles. He had read and remembered much; but what he borrowed he made his own; all was changed, and for the better, by his style and interpretation. He translated into a pungent idiom all that could delight or stimulate the intelligence of his cultured contemporaries. He was a deep admirer of classicism, and to the end of his life, when he mentioned Molière, Racine or Stendhal his conversation or his writing attained their richest substance and most pleasant harmonies.

He makes another strong claim on the attention of posterity. He was the finest flower of the Latin genius. His knowledge of antiquity was great, and his work contained the essentials of Greek and Latin wisdom. He portrayed in *Thaïs* characters who distil the philosophy of the ancients. He put into the mouth of Jérôme Coignard maxims which likewise represent the sum of the meditations and arguments common to antiquity. If all the works of the Hellenic and Roman periods were lost their shadow and purpose might be found in the works of Anatole France. He knew what he owed them, and paid them the most splendid homage.

Lastly, in all periods of his career, whatever his theories, he was a deep student of human nature. He expressed in tuneful sentences most of the wisdom that may be acquired from the observation of life and the reading of history. He created characters who persist in the memory: Jérôme Coignard, Jacques Tournebroche, M. Bergeret, Madame Martin Bellême, Catherine, the lace worker, Paphmuce, Nicias, Evariste Gamelin. He described what was comic and evil in mortals. He described, too, what was august in man, sacred in man's labours and sufferings. Though he lacked enthusiasm and ardour, his critical intelligence did not prevent him from brooding over human misery, and in the story of Crainquebille he showed his heart. While humbling himself before the invincible forces of fate and lust, he dedicated his work now to irony—which brought brightness into his life—and now to pity—which at other times reminded him that life deserves a serious, a solemn attention. And so he became twice fortunate, for he was at once a subtle artist acclaimed by the critics and a universally respected publicist who influenced the simple-minded. He died at Tours, Oct. 13 1924.

The works of Anatole France have been translated and edited by Frederic Chapman and James Lewis May and published by The Bodley Head, London.

FRANCE (*see* 10.775), a republic of Western Europe and member of the League of Nations. The area of France, increased on Nov. 11 1918 by the addition of Alsace-Lorraine, is now 212,73 sq. miles. Her domiciled population (1921) was 39,209,518.

I. POLITICAL HISTORY

The situation of France at the beginning of 1911 was difficult enough, though no acute trouble was manifest at any point to account for the general uneasiness everywhere apparent. In Nov. 1910 M. Briand, after breaking the great railway strike, reconstructed the Ministry, over which he had presided since the fall of M. Clemenceau in July 1909, to include a larger proportion of Moderate elements. As is usual in such cases, the reconstruction had disintegrated the governmental majority instead of strengthening it. The Chamber elected in 1910 leaned further to the Left than the Prime Minister, and showed its dissatisfaction by reducing the majority to 16 on a vote of confidence on the application of the Congregation Laws. M. Briand might still have remained in power had he really wished, but he preferred to resign (Feb. 20 1911) with honour rather than cling to office. Although himself sprung from the Socialist ranks, he felt the necessity of preserving public order against subversive elements, and saw that the deputies were more and more inclined to force the issue, and moreover, he saw no way of extricating himself satisfactorily from the very delicate negotiations with Germany.

The Years Before the War

The Conflict over Morocco.—Since the Algeciras Conference in 1909 French diplomacy had alternated between two courses. Confident in the Russian alliance and the Entente of April 8 1904 with England, she had effectively resisted German pressure. But she saw on all sides evidence that Germany intended to obtain by indirect means what she had failed to win by intimidation—a footing in Morocco and the disruption of the Triple Entente. The Berlin Cabinet took every opportunity of thwarting the organisation of a French protectorate in the Shereefian Empire; moreover, acting in conjunction with Vienna, they persistently insinuated in political and journalistic circles in Paris that France would enjoy greater facilities in Morocco in return for complaisance towards German expansion in the East. This alluring propaganda had its effect upon the Radicals and Socialists, while the Russian Alliance and the Entente Cordiale found favour mainly among the Conservatives, Progressives and Liberals. To the Left of these parties—whom the pacifists accused of militarism—hopes were entertained of an understanding with Germany which, by removing the risk of war, would permit of the normal development of democratic institutions. M. Pichon, Foreign Minister in the Clemenceau and Briand cabinets, did not share this view; but, inspired with a great desire for conciliation, he gave certain confidential assurances to Berlin, supplementing the Franco-German declaration of Feb. 9 1909, under which nationals of both countries were to be associated in Morocco in any transactions for which they could obtain contracts. But at the beginning of 1911 the cabinets of Paris and Berlin were in fact in complete disagreement on the application of the 1909 declaration, and it was therefore without regret that Pichon left the Quai d'Orsay.

Monis, a senator from La Gironde, formed (March 2) a Radical Ministry, giving Caillaux Finance, Berteaux War, Steeg Public Instruction, Delcassé the Navy, Messimy the Colonies and Paul-Boncour Labour. He immediately found himself in difficulties of various kinds. Himself opposed to proportional representation, he had to deal with a Chamber which favoured this method; and although he yielded to Socialist pressure on social questions he was unable to calm the effervescence of the extreme Left. In the department of Aube he was eatened by a quasi-revolt of the vine-growers, whose right sell their wine under the name of champagne had been dis- ted. The Moroccan question was again disquieting. The ongest personality in the Ministry was Caillaux, who, though stood for better relations with Germany, cherished the ambi- n of "giving" Morocco to France—that is to say, releasing protectorate in Morocco from the obligations of Algeciras by angement with Berlin. With the concurrence of Berteaux pressed forward the Morocco campaign. His Foreign Min- er, the lawyer Cruppi, failed to realise the risk of military tiative without diplomatic preparation. In April, when the ench troops entered Fez, Germany formulated reservations, d Spain claimed her right to similar military occupations, tably at Larache. The question of calling a second conference once arose; at the moment of this diplomatic crisis a tragic cident put an end to the Monis Ministry, for Berteaux was led and Monis seriously wounded (May 20) by the fall of an roplane on the aerodrome at Issy-les-Moulineaux. For a nth the Govt. struggled on. The Senate settled the Aube ne question by removing the strict definition of champagne. June 23 the Govt. was defeated in the Chamber, and resigned.

Invited to form a ministry, Caillaux took the Interior himself, signed Finance to Klotz, left Steeg and Delcassé at Public struction and the Navy, gave Messimy War and entrusted reign Affairs to de Selves, a senator and a successful prefect of e Seine. Caillaux's programme included a project for the eorganisation of Africa." This scheme, previously worked out th Messimy, had formed the subject of secret negotiation th the German Govt. in the spring. At that time the proposals tailed the cession to Germany of the political administration of ench Equatorial Africa under the form of railway exploitation. document, which was to remain secret, stipulated that: "if the nstruction of the railway is authorised, Germany may be prac- ally assured that sooner or later Cameroon will be able to annex e Sanga, Ubangi and Shari basins. The economic preponder- ce of Germany in these countries will in effect inevitably entail r political ascendancy."[1] This move, which meant disguised nexation, failed; but the German Govt., disillusioned by the lure of the agreements made with the Briand Ministry, pro- ded with a definite plan. Jules Cambon, French ambassador Berlin, went to Kissingen during the ministerial crisis to talk er matters with Kiderlen-Waechter.

The Agadir Incident.—On July 1, the day after the reading of e ministerial declaration in Parliament, the reply came. Ger- nv's representatives abroad notified all the Powers signatory the Act of Algeciras that in response to the appeal of German mmercial firms and of German protégés for the protection of gadir, their Government had sent a warship, the "Panther," to e Moroccan port. This brusque announcement, which meant that ance must either forego the military protectorate of Morocco or mpensate Germany, was made two days before the date fixed r the embarkation of the President, M. Fallières, and the For- gn Minister, M. de Selves, on a visit to the Queen of Holland. or four months the new Ministry was absorbed in extremely licate negotiations. Confronted with the uncompromising titude of Great Britain and Russia, Germany, whose military d naval equipment was not yet complete, did not persist in r original claims on the Congo. To hasten the issue, Caillaux ntured, unknown to de Selves, to make to Berlin secret pro- sals exceeding the limits conceived possible by the Foreign inister. Disagreeable complications ensued. Finally, on Nov. a treaty was signed ceding to Germany territory which gave cess to the Ubangi and the Congo and organising an economic otectorate in Morocco.

The bill for the ratification of the treaty provoked stormy bates in the Chamber. It was passed at the end of Dec.; but ien, some days later, M. Caillaux's secret offers were disclosed the Commission on Foreign Affairs of the Senate, at which on Bourgeois presided, there was a dramatic scene which led de Selves's resignation. Caillaux offered the Foreign Office to M. Delcassé, who hesitated; the Marine successively to Poincaré, Admiral Germinet and Pierre Baudin, who refused. Finding it impossible to complete his Cabinet, the Prime Minister resigned on Jan. 10.

The replacement of a third of the Senate on the first Sunday in Jan. 1912 produced no sensible modification in either the spirit or the composition of the Upper Chamber.

At the request of Fallières, Raymond Poincaré now quickly formed a ministry. Taking the Foreign Office himself, he made Briand Minister of Justice, gave Léon Bourgeois Labour, Steeg the Interior and Delcassé the Navy. In his declaration on Jan. 16 he announced as his programme the prompt ratification of the treaty of Nov. 4, an *entente loyale* with Spain, courteous and frank relations with Germany, loyalty to alliances and friendships, the restoration of the principle of authority, rigid repression of crime and of offences against persons or property and electoral reform. Under the influence of the Prime Minister moderate ideas began to find favour. When Henri Brisson died, Paul Deschanel was elected to succeed him as president of the Chamber. The municipal elections in May were in favour of the Moderates. A rather complicated franchise Act embodying proportional representation was passed by the Chamber. But, as in the previous year, attention was riveted primarily upon foreign affairs.

A treaty providing for the protectorate was signed by the Sultan of Morocco on March 30, and Gen. Lyautey was appointed Resident-General. There followed disturbances at Fez, negotiations with Spain and long discussions in Parliament. The Sultan Moulai-Hafid abdicated, and was replaced by Moulai-Youssef. The liquidation of the Moroccan affair was attended by a series of complications.

The Balkan Crisis.—Italy had thought it necessary to undertake a parallel enterprise in Tripoli, thus involving herself in a war with Turkey. Certain questions of neutrality arising out of this led to unpleasant incidents, one of which—that of the "Carthage" and the "Manouba"—caused acute tension between Paris and Rome. Here arbitration prevented actual conflict. But the annexation pure and simple of the whole of Libya by Italy, the closing of the Dardanelles and various other incidents aroused such excitement and such hopes in the Balkans that a Balkan League was formed for the purpose of liberating the Christian races on the peninsula. Poincaré was briefly informed of this by Izvolski on April 1, and of the details only in Aug. on the occasion of his visit to Nicholas II. at St. Petersburg. He attempted to intervene as a moderator, but the German and Austrian cabinets which had had warning from secret sources at the beginning of April, allowed events to take their course in the hope that Serbia might be crushed. During the Balkan wars Poincaré continued to urge the localisation of the conflict and the maintenance by the Great Powers of a disinterested attitude in respect of territory. At the London Conference, which opened in Dec., his thesis was: "The Balkans for the Balkan States."

The diplomatic crisis had become serious over the question of Scutari and of Serbia's access to the sea when, Fallières's tenure of office having expired, Poincaré was elected President of the Republic (Jan. 17 1913) by 483 votes against Pams with 269. He carried the day in spite of Clemenceau and the preliminary nomination of Pams by a majority of the Left groups. In his presidential address to the Chambers he made clear his intention to take a more active part than his predecessors had done in the politics of his country. "Weakening of the executive power" he said, "is no part of the creed of Chamber or Country." He insisted further on the necessity of maintaining the military power of France at its highest level, for "it is not possible for a nation to have an effectively pacific policy unless it be always prepared for war."

Briand's Cabinet of Jan. 1913 was formed in accordance with these ideas. Taking the Interior himself, he gave Foreign Affairs to Jonnart and Justice to Barthou, leaving most of the other ministers in their offices. He demanded extraordinary credits for material of war, and put forward a bill for the re-establishment of three years' service, proposing thus to counterbalance the military measures of the German Govt., which had asked for a special grant of a milliard marks for the reorganisation of the army (*see* Germany). Meanwhile he was placed in a minority in the Senate on the question of proportional representation and, on March 18, gave in his resignation.

---

[1] *Documents secrets*, published by A.G. Journal des Débats Jan. 11 12.

Barthou, who now became Prime Minister, with Pichon as his Foreign Minister, set himself to secure the passing of the Three Years' Service bill, considered indispensable for national security by the French general staff. Meanwhile he decided to retain with the colours the class whose term of service would expire in October. It was only after a hard struggle and in the face of violent opposition from the Socialists throughout the country that the bill was passed by the Chamber, and then only with an amendment made by Painlevé which placed recruitment a year earlier, at 20 instead of 21, so that the 1912 and 1913 classes were called up together, allowing the 1910 class to be released at the appointed time. The Senate passed the bill almost unanimously.

Barthou's ultimate success was due to the ever-growing menace of a European war. In April a petty dispute between German travellers at Nancy and the inhabitants nearly led to a diplomatic quarrel. Even when the peace of Bucharest (Aug. 10 1913) ended the second Balkan War, the air was still charged with electricity, both in Europe and the East. In France anxiety increased with the rapid growth of pan-Germanism and the concentrated pressure exercised on the Quai d'Orsay by the cabinets of Vienna and Berlin with the object of raising loans to drain French savings invested in those countries which were under the influence of the two empires. In the beginning of Nov. Pichon learned through Jules Cambon, who had been confidentially charged by the King of the Belgians to convey the warning to the French Govt., that the Kaiser had said to King Albert at his official visit to Potsdam: "War with France is inevitable and imminent. . . . . This time it must be decisive. Your Majesty can have no conception of the irresistible enthusiasm that will sweep over the entire German nation when that day comes." Other remarks, of no less grave import, were made by von Moltke, chief of the German general staff, who was in attendance.

Vigorously attacked by the Left, Barthou had to contend with strong opposition from the Radicals, led by Caillaux, and the Socialists. After the parliamentary vacation his majority collapsed on a question of finance. The floating debt, which had been increased by the expenses in Morocco, made it necessary to raise a loan. The loan proposed by Dumont, Minister of Finance, was defeated by 290 to 265. The objection to the extension of the guarantee of fiscal immunity enjoyed by the existing *rentes* to the new *rente* demanded by the minister was, however, only the nominal pretext; the real opposition of the Left was due to Dumont's refusal to impose an income tax.

Ribot and Jean Dupuy failed successively in their attempts to form a Moderate cabinet on account of Radical opposition of which Caillaux was the rallying point. Poincaré, mindful of Caillaux's diplomatic activities in 1911, was unwilling to put him into power. He therefore instructed Doumergue to form a Radical ministry in which that statesman would take Foreign Affairs. Doumergue entrusted Caillaux with Finance, René Renoult with the Interior and Viviani with Public Instruction. He obtained a vote of confidence from the Chamber (302 votes against 141) for "a policy of democratic reforms, based on republican opinion and supported by an exclusively republican majority." This new Govt. indicated a reversion to the sectarian policy known as "Combisme." It was in favour of a tax on income, which was adopted by the Chamber. The reform of the franchise was definitely rejected by the Senate in March, and the approaching elections were therefore to be on the old basis of the *scrutin d'arrondissement.*

The Menace of "Preventive" War.—Although the Ministry had promised the loyal application of the Three Years' Service law, it was known to dislike the system. But the external situation became more and more disquieting. German militarism entered upon a provocative phase. The Zabern incident (*see* Alsace-Lorraine) produced a deep impression throughout the country. In March the *Kölnische Zeitung* stated that the "legend" of historical Russo-German friendship had been finally exploded. The question of the "preventive" war was openly discussed in the principal Berlin papers. The *Kreuzzeitung* expressed regret that Germany, in 1905, had missed the opportunity of demanding a decisive explanation from France when the conditions were most favourable. The *Berliner Tageblatt* held the view that "in certain cases, a state surrounded by too powerful neighbours owed it to herself not to wait for the knock-out blow to be delivered." It and other papers declared that Germany must make haste to act before the Habsburg Empire fell to pieces. For several weeks the newspapers harped on this theme. The cordial sentiments exchanged at the Elysée on April 21, when the King and Queen of England visited Paris, reassured the public for a time; but fresh signs of trouble soon disturbed its peace. A noisy campaign was organised in Germany against the Foreign Legion, and complications arose at various points in the East.

The Assassination of Gaston Calmette, and the Elections.—A sensation was caused on the eve of the elections by the assassination of Gaston Calmette, editor of the *Figaro*, by Madame Caillaux. On Caillaux's resignation Renoult became Minister of Finance, and Malvy Minister of the Interior. The elections took place a month later (April 26 and May 10). The re-election of Deschanel by 401 votes as president of the Chamber made a majority for the Radicals and Socialists seem unlikely. All the vice-presidents too were chosen from among the partisans of the Three Years' Service bill. Nevertheless the Unified Socialists carried 102 seats, and the Radicals were reinforced; their combined strength was such that no Cabinet could dispense with their support. Doumergue, deferring to custom, had resigned after the elections, and the President of the Republic appointed Viviani with instructions to maintain the Three Years' Service law. But Viviani, confronted with the opposition of the Radical-Socialists, who demanded a return to two years' service, resigned. Poincaré then called on Ribot, who completed on June 9 a Cabinet composed of Moderates and of friendly Radicals, such as Léon Bourgeois and Jean Dupuy. But this Cabinet fell at the first meeting of the Chamber on June 12, when a majority of 306 against 26 announced the resolve: "to give a vote of confidence only to a government capable of bringing about the union of the Left groups." Ribot had drawn the attention of the Chamber to the gravity of the general situation and the increase in German armaments; but the Socialist deputies, absorbed in their own affairs, maintained that these armaments were not directed against France. Viviani, summoned once more by Poincaré, now found the Radicals more accommodating, and succeeded in his task. He took Foreign Affairs himself; gave Justice to Bienvenu-Martin, the Interior to Malvy, War to Messimy and the Navy to Augagneur. The ministerial declaration announced the Government's intention of applying the Three Years' law until further notice and of carrying into effect the income-tax proposals so long held up by the Senate. The Ministry secured a vote of confidence by 370 against 137 votes.

The European Crisis

On June 28 the Archduke Francis Ferdinand and his wife were assassinated at Sarajevo by two Bosnians who were Austro-Hungarian subjects. While diplomatic and military preparations for a war of aggression were being carried on in the greatest secrecy in Vienna and Berlin, President Poincaré and Viviani were embarking for Russia on a visit to the Tsar, while the French people were passionately absorbed in the proceedings against Madame Caillaux (July 20–8) at the Seine assizes. The verdict of acquittal produced a great sensation, but at this very moment the designs of Austria and Germany were revealed in a flash. Poincaré had scarcely left Russia, on July 23, when—at a moment chosen by Vienna and Berlin to prevent the President and the Tsar from coming to any agreement—the Austro-Hungarian Foreign Minister sent Serbia an ultimatum couched in terms which were intended to make it unacceptable. In Paris, the Austrian and German ambassadors declared to Bienvenu-Martin ting Premier and Foreign Minister, that the conflict was be localised to Austria and Serbia. M. de Schoen added that any intervention by another Power would, automatically, der the existing alliances, produce incalculable results." A reless message led Poincaré and Viviani to cut short their pro-sed stay in Stockholm and cancel their visits to Christiania d Copenhagen; they arrived at Dunkirk on July 29.

On resuming the direction of affairs on the night of the 29–th, Viviani found the situation desperate On the night of e 25th Austria had broken off diplomatic relations with Serbia, d declared war on the 28th. At the Quai d'Orsay Schoen in-tently demanded from Bienvenu-Martin and Philippe Berthe- a public declaration of the "political solidarity of France d Germany"—that is to say, the abandonment of Russia by ance. On the 31st Graf Lichtenfeld, Bavarian Charge d'Af-res in Berlin, informed Munich that "the Prussian great neral staff face war against France with the most complete nfidence and count upon the complete defeat of France in ur weeks."

During the presidential voyage anxious French Socialists had t in touch with German Socialists at Brussels. Jouhaux, gen-al secretary of the *Confédération générale du travail*, inquired tegorically of Legien, the Social-democrat representative, ether his party would allow themselves to be mobilised in se of aggression on the part of Germany. He received no reply. the morning of the 31st the German Govt. declared a "state emergency" (Kriegsgefahrzustand) preliminary to general obilisation. On the same day the Austrian and Russian gov-nments simultaneously ordered a general mobilisation. At 30 P.M., Bethmann Hollweg desired Schoen to inform Viviani at the German mobilisation inevitably meant war, and to ask m whether in a war between Russia and Germany France uld remain neutral. His concluding instructions—marked secret"—to Schoen were:

> If, as there is no reason to suppose, the French Govt. should clare that they will remain neutral, I beg your Excellency to orm the French Govt. that we should require, as pledges of their utrality, the handing-over of the fortresses of Toul and Verdun; ese we should occupy and return after the war. The reply to this estion should be in our hands before 4 P.M. to-morrow.

At 7 o'clock Schoen fulfilled his mission to the Quai d'Orsay. few minutes later, Jean Jaurès, leader of the French Socialist rty, who had returned, greatly disheartened, from Brussels, s assassinated by a fanatic in a restaurant. During the day ree councils were held at the Elysée. Poincaré sent King eorge an urgent letter, insisting on the importance of unity of plomatic action on the part of the Triple Entente and on the oderating effect that could not fail to be produced in Vienna d Berlin by the certainty "that the Entente Cordiale would affirmed, in case of need, even to the extent of taking the field le by side." In spite of the extreme gravity of the situation viani had not yet ordered general mobilisation, but only the mpletion of the second defence line. No moderating influence uld now alter the course of events, determined by the two ntral Powers. The French Govt. had concurred in all the itish and Russian proposals for the prevention of a general nflagration, whether by the summoning of a conference, by bitration by the Hague Court, or by mediation. In spite of me wavering between Vienna and Berlin at the eleventh hour e situation was so well defined that Schoen made his prepara-ons for departure on the evening of the 31st, without waiting the reply that Viviani was to give him the next day. With e "punishment" of Serbia as the initial pretext, the conflict sensibly assumed the form desired by the German general aff. From Austro-Serbian and Austro-Russian it became Ger-an-French, without a mistake or even the slightest imprudence ving been committed at any point by the French Government.

The Declarations of War.—On Aug. 1, without awaiting replies om France and Russia, William II. approved the text of the clarations of war against these two Powers. The Federal ouncil assembled in Berlin took note of the two documents, d agreed to their dispatch in case the expccted replies should prove unsatisfactory. At 11 A.M. Viviani replied to Schoen that France would do what her interests demanded. There was no mention of Toul and Verdun by Schoen. At 3:40 P.M. France ordered a general mobilisation. At the same hour, and before the arrival in Berlin of Schoen's telegram relating his interview with Viviani, the order for general mobilisation was given in Berlin, the public announcement following at 5 o'clock. At 5:30 Schoen went again to the Quai d'Orsay, where Viviani expressed to him his hope that, in spite of the mobilisation, negotiations would be continued on the basis of the most recent proposal put forward by England, which had the warm support of the French Cabinet. At 7 P.M. Count Pourtalès delivered Germany's declaration of war to Sazonov. At midnight Izvolski appeared at the Elysée, where a Cabinet meeting was in progress, to ask what France intended to do. The Cabinet decision was to fulfil all the obligations of the Alliance, but that France should not take the initiative in breaking off relations nor declare war. A state of siege was proclaimed, and the Chambers were convoked for the following Tuesday. During the night German detachments invaded French territory at four different points.

On the morning of Aug. 2 a French corporal was killed on the Delle road by a German lieutenant who had entered France at the head of a patrol. In Berlin the expediency of an immediate invasion of France was being discussed. After consulting the war ministers and the general staff, the Chancellor decided in the negative. "We hope," he reported to the Kaiser, "that the French will attack us." But this hope was not realised, the French troops having orders not to respond to provocation. The German Cabinet then ordered the German Minister at Brussels to carry out the instructions contained in a sealed note that had been sent with a telegram on July 29; these instructions were that the Belgian Govt. be summoned to allow the passage of the German Army. At the same time the chief of the German Admiralty informed the commander of the fleet that hostilities against France would probably commence on Aug. 3. The Belgian Govt. rejected the German summons, as also the proposal of H. Klobukowski, the French Minister, to send five French army corps to defend Belgium's neutrality. In London assurances were made to M. Cambon by Sir Edward Grey that if the German Fleet came into the Channel or through the North Sea to undertake military operations against the French coast or shipping, the British Fleet would give all the protection in its power, and that the British Govt. were considering whether they would declare in Parliament the next day that the violation of Belgium should be regarded as a *casus belli*.

On Aug. 3, France having nowhere furnished any pretext for aggression, the German authorities spread false reports of supposed invasions of German soil or German skies by French soldiers. Bethmann Hollweg telegraphed to all the European capitals that "France's action was the most serious violation of neutrality imaginable." Between 1 and 2 o'clock he ordered Schoen to deliver to the French Govt. at 6 P.M. the same day a declaration of war couched in these terms:—

> The German administrative and military authorities have established a certain number of flagrantly hostile acts committed on German territory by French military aviators. Several of these have openly violated the neutrality of Belgium by flying over the territory of that country. One has attempted to destroy buildings near Wesel; others have been seen in the district of the Eifel, one has thrown bombs on the railway near Karlsruhe and Nürnberg. I am instructed, and I have the honour to inform your Excellency that, in the presence of these acts of aggression, the German Empire considers itself in a state of war with France in consequence of the acts of this latter Power.

Viviani made vigorous protests both to Schoen and in a note sent to the representatives of the Powers in Paris. There was some brawling in the streets of the capital where German or Austro-Hungarian subjects owned shops and some of these were pillaged. But order once being restored by Viviani, no further disturbance took place in the following days. That evening he reconstructed his Cabinet to suit the circumstances, himself remaining president of the council but relinquishing Foreign Affairs, which passed to Doumergue. Augagneur succeeded Gauthier for the Navy.

On Aug. 4, amid general excitement but without disturbance anywhere, Parliament reassembled to hear the Government's communication. In his message the President of the Republic recalled the fact that for over 40 years France, resolutely putting aside her desire for legitimate reparation, had used her rejuvenated energy solely in the interest of progress and for the good of humanity; that she might be justly proud of having made supreme efforts to avert the war which had just broken out, the crushing responsibility of which would be laid upon the German Empire by history. The message, to which the two Assemblies, greatly moved, listened standing, proclaimed the "*union sacrée*" of all sons of France. Viviani then explained at length the events and negotiations that had taken place, concluding with these words: "We are without fear, we shall be without reproach." Thus invoked, the "sacred union" became a reality. Even as the army mobilisation proceeded throughout the country in perfect order, so the mobilisation of the spirit, which prepared the population to endure long and terrible trials, was effected with a quiet dignity. Parties ceased to exist. Bowing to the evidence of German aggression the Socialists stood loyally by the Government. They sought no vengeance for the murder of Jaurès, and the Viviani Cabinet, confident in their patriotism, refrained from using their discretionary powers of preventive arrest even on the most suspect in their ranks—those whose names were on "List B." The whole country, moved by one will, rose with the same enthusiasm against the invader.

By a succession of laws, passed without debate, the country was organised for a state of war. The state of siege was to be maintained for the duration of the War; commercial settlements were postponed and credits prolonged; legal proceedings against citizens called up for service were suspended, and a moratorium was decreed for bank deposits. Allowances were voted for necessitous families whose breadwinners were in the army; the Govt. was authorised to open by decree credits for the requirements of national defence. Notes on the Banque de France became compulsory currency, and the limit of emission was raised to 12 milliards. Measures were taken against alcoholism, in particular the sale of absinthe was forbidden. To avoid press indiscretions it was forbidden, under penalty of imprisonment, to publish any information regarding national defence apart from that given in official communications, or any military or any diplomatic article of a nature "favourable to the enemy or calculated to depress the minds of the army and the population." No preventive censorship was established, but a Press bureau installed at the Ministry of War received the damp proof-sheets of the newspapers and marked such passages as were not to be printed. Any paper which failed to comply was liable to be warned, and, in case of a second offence, suspended. The passages suppressed were represented by blank spaces as it was impossible to replace them at the last moment; these were known as "caviare."

In a few days the conflagration had spread from one end of Europe to the other. Austria, however—the original instigator—affected a sort of ignorance of events in her relation to France. Her ambassador continued his functions in Paris. Under pressure of public opinion, infuriated by this cynical attitude, Doumergue sent Graf Szecsen his passports on Aug. 10 and instructed Dumaine to ask for his. The British Cabinet followed the same course with regard to Count Mensdorff.

The War Period

After the loss of the battle of the frontiers (Aug. 20–4) the Ministry realised the need of reconstruction or—as Viviani phrased it—of broadening its basis. On Aug. 26 the government of National Defence was constituted, containing representatives of the Republican parties, and including for the first time two Socialists, Guesde and Sembat. Viviani remained as Prime Minister without portfolio; with Briand, Delcassé, Malvy, Millerand, Ribot, Sarraut and Doumergue. At the same time Jouhaux, together with the Archbishop of Paris, Cardinal Amette, was appointed to the National Aid committee (*Comité de l'oeuvre du secours national*), created for the assistance of refugees from the invaded departments and presided over by the head of the Paris Faculty of Science, M. Appel. No sooner was the new Govt. formed than it departed to Bordeaux (Sept. 3) unwilling to risk being shut up in Paris as in 1870. The capital was left in the hands of a military governor, Gen. Galliéni, whose short proclamation became famous: "Inhabitants of Paris, the members of the Govt. of the Republic have left Paris in order to give a new impulse to National Defence. I have received a mandate to defend Paris against the invader; this mandate I shall carry out to the end" (Sept. 3). Nevertheless more than a third of the population left the city. German aeroplanes flew over Paris daily.

The installation at Bordeaux of the Govt., the foreign missions, the principal departments of state, the most important Paris newspapers, and a multitude of pusillanimous or curious persons was not effected without some disorder at first, and even some scandals. But life in the provisional capital rapidly attained the necessary dignity. On the side of the Govt. it showed great activity. On Sept. 5 M. Delcassé obtained through M. Cambon a declaration signed in London by which the British, French and Russian governments mutually agreed to conclude no separate peace during the existing War, nor, when peace terms came to be discussed, to propose conditions without first coming to an agreement with each of the other Allies.

The victory of the Marne (Sept. 6–10) brought relief, and, indeed, gave rise to exaggerated hopes; but disillusionment was to follow. On Aug. 2 a German-Turkish alliance had been concluded, unknown to the ambassadors of the Triple Entente duped by the triumvirate Talaat-Enver-Djemal; there followed the disaster of Tannenberg, the penetration of the "Goeben" and the "Breslau" into the Sea of Marmara, and Turkey's entry into the War on the side of Germany at the end of October. Munitions became exhausted and the line of trenches now extended continuously from the Vosges to the sea. Paris was no longer in danger, but six departments had been invaded, and none could say when they would be liberated. The situation being thus stabilised, the Govt. was reinstalled in Paris in the latter half of December. The Chambers which had not sat at Bordeaux, although assembly rooms had been reserved for them, met again on Dec. 22. Thenceforward they were to be permanently in session with but few interruptions. The experience of the preceding months had shown that there were serious objections to the suppression of Parliament and of the Press. An outside stimulus was needed to correct the errors of judgment and fatal imprudences that had been committed. In the Chamber the criticisms were many and vigorous; notably these formulated with asperity by Clemenceau in his paper *l'Homme Libre* which, after being suppressed by the censor, reappeared as *l'Homme Enchaîné*. But Viviani was able to curb excessive recriminations in the Chamber and to insist on the maintenance of the *union sacrée*. He consented to the formation of big parliamentary commissions, which were to prove discreet and very useful collaborators of the Government. Certain deputies and senators were sent on missions to the armies.

Annual budgets were dispensed with. All credits were voted by douzièmes described as provisional. As taxes were not coming in well and it was considered impolitic to raise them at a time when the nation's whole resources were being strained to restrict invasion, resort was had to loans. The most successful financial resource was the issue of National Defence bonds, which had been Ribot's idea. These were actually Treasury bonds in the form of coupons bearing a fixed rate of interest, payable in advance, which could be realised at three, six or 12 months and were negotiable at sight.

The Ministry was vigorously attacked on the subject of the men—named *embusqués*—mobilised or liable to be mobilised, who shirked service at the front. In the hurry to produce munitions many factories had to be set working again and authority was given to their directors to recall such of their workpeople or staff as seemed to them indispensable. Similarly, members of the universities and specialists whose technical knowledge was indispensable to different services, had to be allotted to non-combatant corps. As a result the trenches had been held, since the middle of 1915, mainly by peasants and employees. On the itiative of Dalbiez, therefore, the Chamber passed a rigorous w (June 26), which did not however entirely remove the *em*- *ısqués* scandal. In July two under-secretaryships were created: oseph Thierry for supply and Justin Godard for the medical rvices. The discussion aroused by all these complicated ques- ons weakened Millerand's position. In the Senate, Clemenceau, s president of the Army Commission, carried on a ruthless cam- ıign for the adaptation of the services to the needs revealed by ıe War.

The Intervention of Italy.—In the field of foreign politics the ɔring was a period of great promise followed by great disappoint- .ent. In the Dardanelles the naval expedition sent to force the traits failed (March 18) with heavy losses. In May there was y on hearing of Italy's intervention on the side of the Allies. A eaty between the Triple Entente and Italy, of which the tenor mained a secret for the whole of the War, had been signed on pril 26 in London. Although the clauses relating to the pro- ɔsed cession to Italy of territory inhabited by Slavs were not vulged, they were known in substance to the Slav peoples and eated great indignation, thus strengthening Austro-Hungarian sistance. Then, too, in defiance of a formal stipulation in the reaty of London, Sonnino declared war on Austria only. It was ɔt until Aug. of the following year that he declared war on Ger- .any, who benefited meanwhile by Italy's neutrality. Then gain, England and France, who were already providing military ıaterial for Russia, had now to manufacture it for Italy also, though they had not enough for themselves. The crowning umiliation was Rumania's failure to come in till over a year ter instead of with Italy, as the Allies had expected.

The Intervention of Bulgaria.—Yet another intervention was follow, disconcerting the Allied Ministers and precipitating ıe fall of Viviani's Cabinet. When Bulgaria ordered a general obilisation on Sept. 22, the Allies flattered themselves that it as directed against Turkey. For three days Delcassé and Mil- rand denied the evidence. When the truth came out, Delcassé, being questioned in the Chamber, was subjected to such vere criticism that he had to retire. Viviani then took over ıe portfolio of Foreign Affairs (Oct. 13). He was still able to otain a vote of confidence of 372 to 9; but, by the abstention the Socialists and a large number of Radicals, the *union sacrée* as broken. Viviani was a victim of the general uneasiness used by successive disappointments and by the non-success of ıe great offensive in Champagne (Sept. 15). Sensible of the saffection of the majority, who were opposed to the secret ommittees instituted by the Chamber, Viviani handed in his signation on Oct. 28.

Briand rapidly formed a new Cabinet, keeping Foreign Affairs mself. The Ministry of Justice fell to Viviani, War to Gen. alliéni, Navy to Adm. Lacaze, Public Instruction and Invention Painlevé; Ribot retained Finance and Malvy the Interior. ive seats in the Cabinet without portfolio were created for de reycinet, Léon Bourgeois, Combes, Guesde and Denys Cachin, ıd an Under-Secretariat for Munitions for Albert Thomas, the oung Socialist deputy. The Ministry, which embraced political eterans of all parties and some new men in addition, was unusu- ly well received. Briand's speech, taking as its motto: "peace rough victory," was followed by a vote of confidence in the hamber of 516 to 1. The *union sacrée* seemed to be restored in ite of the sympathy shown by a considerable and energetic ocialist minority with the pacifist resolutions passed at the In- rnational Socialist conference at Zimmerwald early in Septem- er. This minority grew gradually bolder. At the second Interna- onal Socialist Conference, held also in Switzerland at Kienthal April 1916, three French deputies presented themselves.

Restrictions and Finance.—In spite of goodwill the Briand abinet had some hard knocks at home and abroad. In the ope of preventing a rise in the price of essential foods and of owing down the increase in the cost of living, the Govt. pro- ded the bakers with flour (at a loss) and fixed maximum prices r certain commodities. They had eventually to proceed to ricter measures and to ration each family for bread, coal and gar. Summer time, introduced in June for the sake of economising coal, was maintained in spite of the dislike of the rural population. The prolongation of the War made it more difficult to enforce extraordinary regulations which had been accepted originally as temporary. The restrictions on the consumption of alcohol, to which the trade raised strong objections, and the prohibitions laid down by the military authorities aroused complaints which reverberated unpleasantly in the Chamber. On Feb. 1, 1916 Galliéni, having been rudely interrupted, left the tribune and even the hall. Although he was brought back it was only to complain, "You force me to do work for which I am not fitted." It was not for long. Galliéni, being exhausted and threatened with appendicitis, resigned on March 16. On May 26 he died as the result of an operation. His funeral was made a national event. He was succeeded by Gen. Roques, who was thus the fourth War Minister in 20 months.

The necessity of providing the Treasury with other resources than those raised by loans compelled the Govt. to demand new sacrifices. A tax on income, passed by the Chamber before the War, but laid aside by the Senate, had already been imposed; but owing to the respite granted to mobilised men only 133,000 were found to have an income over 5,000 fr. (the minimum taxable figure), and as their total income was under three milliards, only half the expected sum was realised. Ribot hoped at least to cover the interest on new loans by the tax. He therefore proposed to double the tax on land, the tax on income, and to increase the duties on tobacco, sugar and alcohol; also to suppress the rights of vineyard proprietors to distil without paying duty on the yield of their vintage. On this latter point in particular Ribot met much opposition, and exemption on 10 litres of pure alcohol per family was conceded. The Senate accepted this condition, though objecting to the distillers' privileges. The doubling of direct taxes was rejected in favour of a tax on war profits, which from this time onward often appeared excessive. The Socialists took advantage of the national unrest to promote their cause, and internationalism made some headway in the National Council of French Socialists. Late in Aug. a vote was passed protesting against the doctrine which denied that a country had the right to defend itself when attacked, and calling for a durable peace based upon reparation of the wrong done in 1871 and the restoration of independence to oppressed nations. But the minority continued to grow and, by Dec. 28, had 1,081 votes against 1,836. Only by 1,637 votes against 1,372 was Thomas authorised by the party to return to Munitions.

Verdun and the Somme.—During the whole of 1916 military interest was concentrated on the siege of Verdun (*q.v.*). By June the general anxiety had reached such a pitch that Viviani consented to let the Chamber sit in secret committee (June 16–22). After animated discussion a resolution was passed, by 440 against 97, expressing at the same time confidence in the Govt. and the Chamber's desire "to exercise effective control of all services engaged in providing for the requirements of the army . . . while strictly abstaining from interference with the conception, direction or execution of military operations." Actually this control was carried out without serious hitches, and the committee continued to sit in secret whenever the situation was felt by the deputies to be too serious to be discussed at a public sitting.

On July 1 a Franco-British massed attack was launched against the line of the Somme. It was a brilliant performance, with heavy losses on both sides, but the result was negative; for after weeks of struggle the Allied line had only advanced some kilometres to the East. On the second anniversary of the War efforts were made to sustain the morale of the army and the population by proclamations from the President of the Republic, the Prime Minister and the army chiefs. The Govt. urged private individuals to put their gold into the Banque de France and place their realisable foreign securities at the disposal of the state. In response to these appeals some three milliards were collected, making it possible to limit depreciation of the franc to 10 or 12%.

The Eastern Campaigns.—But events in the East took a disastrous turn. The second Dardanelles expedition—no more successful than the first—was abandoned in the autumn, and the troops thus released were sent to Salonika and placed under Gen. Sarrail, who had instructions to go to the aid of Serbia. But Sarrail, lacking adequate means and thwarted by the opposition of King Constantine, was unable to get into touch with the Serbs, whose army retreated under terrible conditions across Albania to the Adriatic. In vain did the British and French governments urge Constantine to range himself on the side of the Allies; he dismissed Veniselos and the Chamber, and persisted in an unfriendly neutrality. Briand opened negotiations with the Greek Govt., which produced nothing but irritation and disappointment to France. On Aug. 17 1916 a treaty of alliance with Rumania brought the Allies renewed hopes of an early victory. But after some success there came a fresh disaster. Rumania was attacked by Bulgaria, on whose neutrality she had relied; the Russian contingents promised to her were delayed, the promised offensive by Sarrail's army was not launched and her territory was finally invaded and occupied by the enemy as far as Moldavia. Encouraged by these events and urged on by Berlin, Constantine went so far as to attack some detachments of French marines on the outskirts of Athens and a number of Veniselists in the streets of the city. French residents had to take refuge with the fleet.

Briand and Adm. Dartige du Fourmet, commanding in Greek waters, had been doubtfully advised in their later negotiations with the Cabinet in Athens. They had in fact speculated on Constantine's goodwill. In France, where the Rumanian catastrophe had come as a surprise, these latest events made a painful impression. A secret committee of the Chamber (Nov. 28–Dec. 7) passed a resolution "taking note of the Government's declarations on the reorganisation of the command and approving its resolution to concentrate on the conduct of the War and its economic organisation." Briand thereupon reconstituted his Cabinet. He suppressed the five ministers of state, made Gen. Lyautey War Minister (replacing him in Morocco by Gen. Gouraud), promoted Thomas to be Minister of Munitions, and gave Herriot Supplies. Loucheur was made Under-Secretary of Munitions. A war committee of five ministers was formed and, at the end of the month, the reform of the high command, so long desired by the many who had lost confidence in Joffre's methods, was timidly brought about. Joffre was attached to the War Committee as technical adviser, and was made a Marshal of France. His successor was neither Foch nor Pétain, but Gen. Nivelle, who was appointed commander of the armies of the north and northeast. But Briand's authority was now seriously impaired. In the Chamber he was subjected to wearisome criticism and recrimination, and the deputies refused him the necessary powers to deal by administrative order with questions affecting national defence. Even the Senate's vote of confidence was only passed by 190 votes against 37. With each successive vote his majority decreased while the number of abstentions steadily increased. At last, during a session in which certain deputies demanded a secret committee on military questions, Gen. Lyautey retorted bluntly that there were some things which could not be said even in secret committee. This suggestion of possible indiscretions—there had been leakages—was greeted with angry murmurs, and Lyautey decided to resign. As Painlevé refused to take his place, Briand tendered the resignation of the whole Cabinet on March 17 1917.

Peace Offers.—One of the last acts of the Cabinet had been the rejection of a disputable offer from the four enemy governments "to enter upon peace negotiations." This proposition, couched in grandiloquent phrases and enhanced by sensational addresses from the heads of the governments in Berlin, Vienna and Sofia, lacked precision. As M. Briand said, speaking on Dec. 1 1916, it was a proposition to "*d'avoir a négocier la paix.*" The Russian, Italian and British ministers denounced its insincerity. About the same time, too, a note from Mr. Lansing invited the belligerents in the name of President Wilson to "take soundings." It was a profound shock to France to see all the belligerents—aggressors and victims—put thus on the same footing. Two days later the Swiss Govt. made a similar move. On Dec. 23 the French Senate announced its determination "to carry on the War which has been imposed upon us to a victorious conclusion." The governments of the other Allies expressed their determination with equal force. On Dec. 30 they sent collective and identical notes to the neutral states charged with the protection of their interests in enemy countries, stating that the conclusion of peace was contingent upon the restoration of rights and liberties that had been violated and recognition of the complete independence of the small states. Wilson still pleaded for "peace without victory" at the Senate on Jan. 22; but, Germany having declared for unrestricted submarine warfare, (Feb. 1) he broke off diplomatic relations with that country on Feb. 3.

Paul Deschanel, the president of the Chamber, having declined to undertake to form the new Ministry, it fell to Ribot to accomplish this task in 24 hours. Taking Foreign Affairs himself, he gave War to Painlevé, Labour to Léon Bourgeois, and retained several of the former Ministers—notably Malvy as Minister of the Interior. Lyautey returned to Morocco. The ministerial declaration, of considerable substance and detail, was approved by 440 votes against 61 abstentions. Ribot was confronted with some extremely important problems. The Russian Revolution, the forced abdication of the Tsar, and the installation of the weak provisional Govt.—soon to be succeeded by the Bolsheviks—upset all the military combinations of the Allies on the eve of a great offensive for which minute preparations had been in progress for months. At the same moment (March 17–24) the Germans effected a strategic retreat on the Somme front, leaving a desert behind them. A formidable problem presented itself: should the offensive, prepared in conjunction with the British, be carried out in spite of the modification in the general conditions unfavourable to the Allies? To what extent should the Govt. interfere in the direction of military operations? Intimate discussions took place between the ministers and Gen. Nivelle. The declaration of war on Germany by the United States (April 6) served, it is true, to restore the equilibrium destroyed by the Russian Revolution, but it would be many months before it could have any effect on the military situation. As the Govt. still hesitated Nivelle offered his resignation, but withdrew it on receiving definite assurance that the offensive would take place as arranged. On April 16 the French troops, who had been magnificent in launching their attack, were brought up against insurmountable obstacles and came to a standstill after heavy losses. The depression felt by the army and the public led, among other changes, to the replacement of Nivelle by Pétain, with Foch as chief of the general staff.

Side by side with military operations, secret negotiations were proceeding between Paris and Vienna. In Jan. and Feb. the Emperor Charles I. commissioned his brother-in-law Prince Sixtus of Bourbon to communicate his desire for peace to President Poincaré. After several journeys Prince Sixtus of Bourbon presented Austria's peace conditions (May 5) at the Elysée. They were the conditions of a conqueror, and the alliance with Germany, Bulgaria and Turkey was again affirmed. After another journey to Vienna, Prince Sixtus returned to the Elysée with a personal letter from the Emperor, who expressed his willingness "to forward in every possible way the just claims of France to Alsace-Lorraine and to use his personal influence with his Allies to that end." Although these conditions were unacceptable to the Allies of France, Poincaré and Ribot did not reject them offhand. On April 19 Ribot went to St. Jean-de-Maurienne with Lloyd George, who had been fully informed, to meet Sonnino. Lloyd George offered Sonnino Smyrna if he would give up Trieste; but the Italian Minister insisted that the conditions of the Treaty of London had represented a minimum and that any concession would provoke risings in Italy which would place the Govt. in danger. Subsequent conversations only attested the impotent vacillation of the Austro-Hungarian Government. Other secret proposals were exchanged during the summer at Fribourg in Switzerland between Count Revertera, for Austria, and Count Armand for the French general staff. But these emphasized the inconsistency of proposals which proved abortive.

French Action in Athens.—It was thought that only by force f arms could the enemy be checkmated. Ribot therefore de- ded, after consulting the British Govt. in London, to settle he Greek question by expelling Constantine and freeing the alonika Expeditionary Force from the risk of attack by the ermanophil Greek forces. He gave full powers to Senator Jon- art, appointed High Commissioner of the Allied Powers for the ccasion. Jonnart left for Brindisi on June 2 and appeared before he Piraeus at the head of a fleet on the 5th. In spite of strong rotests from the British, Italian and Russian Ministers at thens, all of whom were opposed to the expulsion of the King, onnart demanded and obtained Constantine's capitulation, fter having had Thessaly and the Isthmus of Corinth occupied y Allied troops. On June 13 King Constantine left Athens with is family. Jonnart then recalled Veniselos, who had consti- uted a provisional government at Salonika, and the King's econd son, Prince Alexander, was called to the throne with the itle of King Alexander I., his elder brother George being passed ver because of his German sympathies.

The Socialist Movement.—This success was warmly approved n Paris inside and outside Parliament. It helped to consolidate he Cabinet, which, however, was soon to be shaken by the ocialist manoeuvres. At a plenary session of the party held in May, the Socialists had decided to attend the International Congress at Stockholm which had been called with the object of topping the War. The Govt. refused their passports, and the hamber, after a secret session, passed a resolution of approval y 467 votes against 52, and with a further resolution on the onditions of peace that:—

> The Chamber, while countersigning the unanimous protest made o the National Assembly in 1871 by the representatives of Alsace- orraine, forcibly torn from France, announces that it expects, as he result of the War imposed upon Europe by the aggression of mperialist Germany, not only the liberation of invaded territory, ut the restoration of Alsace-Lorraine to the mother-country and ust reparation for damages.

The Chamber further declared itself to be "far from any idea f conquest or of the subjection of foreign populations," and efined the goal towards which the armies of the republic were triving as "the laying down of permanent guarantees of peace nd independence for great and little nations by an organisation f which the basis is now being prepared by the League of Na- ions." On June 7 a similar motion was passed unanimously in he Senate, which in addition requested the Govt. to take all ecessary precautions at home and abroad for the safety of the ation, in view of the number of recent strikes of a suspicious ature in which undesirable foreigners had taken part.

These transient troubles, which yielded to firm handling, coincided with a peace move staged in Berlin (*see* EUROPE), and rumours on the subject of a journey to Leningrad (Petrograd) undertaken by Doumergue and Castelnau under the late Ministry. As regards the latter, Ribot stated in the Chamber on July 31 that Doumergue had made a note of the Tsar's promise to support the re-annexation of Alsace-Lorraine to France and "to leave France free to seek guarantees against renewed aggression, not by annexing the territories on the left bank of the Rhine, but by creating if necessary an autonomous state out of these territories, which would protect us, as well as Belgium, from invasion from beyond the Rhine." Meanwhile disturbances stirred up by Teutonic influences with the aim of depressing French opinion and bringing into power in Paris men who would be willing to take the initiative in peace proposals, provoked a governmental crisis. In view of the anti-patriotic propaganda that was being carried on by means of pamphlets and the revolutionary paper *Le Bonnet Rouge*, the Senate held a secret committee (July 19–20). Clemenceau took Malvy, Minister of the Interior, vigorously to task on the matter of his relations with Almereyda, an adventurer who edited *Le Bonnet Rouge*. This episode marks an epoch in the internal history of France during the War, for it created the schism between the Socialists and the Government.

The Senate and the Chamber successively passed votes of confidence, in spite of the resignation of Adm. Lacaze and Denys Cochin. The Socialist group allowed Albert Thomas to remain in the Cabinet; but the rupture took place, following on the action brought against *Le Bonnet Rouge*. Almereyda, who had been arrested on Aug. 6, was found dead in his cell on the 14th. He had been strangled with one of his bootlaces. The official experts gave a verdict of suicide, but such a suicide was at lowest a singular reflection on the supervision exercised, and public opinion was up in arms. Malvy had been away a few days for his health, but he now resumed his functions. Meanwhile it was learnt that a cheque of suspicious origin which had been seized at the frontier from the director of *Le Bonnet Rouge* had been restored to him by the favour of Leymarie, Director of Public Safety, and at the same time director of the bureau of the minister. Leymarie declared he had acted without consulting the minister, and resigned. On Aug. 31 Malvy, accused of having relations with Almereyda, resigned. It was first thought that the Ministry might be simply reconstituted, but the attempt failed, and the Cabinet resigned on Sept. 7. Ribot, charged with the task of forming a new Ministry, failed, because the Socialists refused to collaborate with him, while Painlevé refused to remain in the Cabinet unless the Socialists came back. The Socialists could not forgive Ribot for refusing passports to Stockholm, and Painlevé was being pushed into power by friends who regarded him as the man of the hour.

Thus it fell to Painlevé to form a Cabinet which, by a curious contradiction, did not include a single Socialist. He was his own War Minister; Ribot retained Foreign Affairs, and Loucheur became Minister of Munitions. On Sept. 18 Painlevé secured a vote of confidence, unanimous but for the abstention of the Socialists and some Radicals (among them Caillaux). The Ministerial Declaration contained nothing new in general policy, but promised that justice would take its course, unhesitatingly and without any respect of persons, in the judicial inquiries then proceeding or about to be opened. This promise the Ministry was almost immediately called upon to fulfil. On Oct. 7 Turmel, a deputy, was arrested for having received money of suspicious origin. Then came the Bolo scandal. It was discovered that Bolo—known as Bolo Pasha, that title having been conferred on him by the former Khedive, now dethroned and an instrument of the Central Powers—had received 10,000,000 fr. in the United States from Von Bernstorff, the German ambassador. With this sum he had bought 1,100 shares in the *Journal*, the editor of which, Senator Charles Humbert, had made himself known by a noisy campaign demanding "guns and munitions." Bolo was arrested on Sept. 29. On Oct. 4 Malvy himself appeared in the dock. The former Minister of the Interior was accused of treason by Léon Daudet, editor of the *Action Française*, in a letter addressed to the President of the Republic, which was read out in the Chamber. After a judicial inquiry the Govt. announced, on Oct. 15, that there was no foundation for Daudet's accusations. The Govt. obtained only 246 votes against 89 in the Chamber on an interpellation on the subject. It was shaken; an outside incident brought about its fall.

The Lancken-Briand Incident.—Meanwhile the Berlin Cabinet, itself torn by internal dissensions, was trying to implicate certain Frenchmen in its *défaitist* negotiations. M. de Lancken, German civil commissioner in Brussels, conveyed proposals to Briand by means of Belgian intermediaries—notably Baron Coppée and his son. He told him that William II. was ready to make peace and to send a qualified personage to Switzerland to confer with the former Prime Minister. Briand wrote to inform Ribot, and suggested the conditions under which conversations might be initiated; but Ribot strongly opposed conversations which might be exploited by the Germans. Lancken therefore waited in vain for Briand at Ouchy, and the matter dropped. But a legend grew in the lobbies of the Chamber to the effect that Ribot had turned down peace feelers which held some promise of the return of Alsace-Lorraine to France. On Oct. 12, when Georges Leygues made an interpellation in the Chamber on the personnel and action of the diplomatic body, Ribot took the opportunity to denounce in veiled language Austria's manoeuvre to separate France from Italy and the pitfalls laid by Germany, "who only the other day, caused perfidious suggestions to be whispered in the ear of a man of high standing." The concluding words of this sentence caused a commotion at the Palais Bourbon, and were therefore suppressed in the official records. On the 16th, the Socialist deputy Mayeras moved to discuss the discrepancy between the words spoken in Parliament and the text as printed. The motion was discussed in a stormy secret committee which gave the Govt. a small majority. Briand's friends, displeased with the allusion of Oct. 12, voted with the Socialists, who were still full of resentment over the refusal of the Stockholm passports. The Cabinet were so badly hit that Painlevé contemplated resignation. Poincaré would not accept his resignation, but Ribot and his other colleagues handed in theirs collectively so as to give the Prime Minister a free hand to reconstruct his Cabinet. On Oct. 28 the Ministry was reconstituted, Painlevé contenting himself with replacing Ribot by Barthou; but far from consolidating the Govt. the substitution only weakened it. The ministerial majority, which had stood at 362 on the 12th and 316 on the 19th, fell to 288 after Painlevé's and Barthou's speeches on the 25th.

Nevertheless, Painlevé took the same attitude as Ribot towards Stockholm, and refused passports for the Congress then in progress. He hoped to appease the Socialists by an investigation of the *Action Française* affair, but the Court found no cause to prosecute. Meanwhile *Le Bonnet Rouge* and the *Journal* scandals grew more serious, and Caillaux himself was attacked in *l'Homme Enchaîné* for his conduct when travelling in Italy. Then came the Italian disaster of Caporetto and the advent of the Bolsheviks in Russia, which made it necessary to hold an inter-Allied conference at Rapallo for the co-ordination of military effort.

The Rapallo conference over, a troubled period set in for France. M. Paix-Séailles, who had formerly been attached to Painlevé's bureau, was accused of divulging information from documents dealing with national defence. Caillaux was brought before the juge d'instruction to give an account of his relations with Bolo Pasha, and had an exchange of letters with Clemenceau which caused a sensation. On Nov. 13 Painlevé announced in the Chamber the results of the Rapallo conference. These were, an extension of the British front, Franco-British economic co-operation, the strengthening of the blockade and the creation of an Inter-Allied Supreme War Council. Only 250 votes were recorded in approval against 192, a further diminution of the Government majority. This was speedily transformed into a minority when the Prime Minister demanded the postponement of motions relating to internal order until after the Inter-Allied Conference to be held at the Quai d'Orsay at the end of the month. The Chamber voted against the postponement by 277 against 186, and at the close of the sitting Painlevé handed his resignation to Poincaré: his authority in Parliament was at an end.

The Clemenceau Ministry.—Public opinion indicated Clemenceau as Prime Minister, the Senate supported the choice, and the Chamber was prepared to acquiesce, little as it liked the remorseless controversialist who criticised ministers and even the President of the Republic so fiercely in *l'Homme Enchaîné*. In spite of his 76 years, Clemenceau was universally regarded as the incarnation of the determination to "fight to a finish," to punish weakness or faltering, whatever their origin, and to subordinate everything to the pursuit of final victory. The great majority of Frenchmen felt that such a man was needed at the head of the Government. Ignoring all other considerations, Poincaré therefore called upon Clemenceau (Nov. 15) to form the new Cabinet. Clemenceau accepted, and completed his mission the next day. He took War himself, confiding Foreign Affairs to Pichon, the Interior to Pams, Navy to Leygues, Munitions to Loucheur, Finance to Klotz; and divided the war services between five under-secretaries. The Ministerial Declaration announced the intention—

> to carry on the War, to punish crime and faltering: weakness would be complicity. Accused persons to be tried by court-martial. No more pacifist campaigns, no more German conspiracies; neither treason nor demi-treason; but the War and nothing but the War. Our armies shall not be caught between two fires. Law shall prevail. The country shall know that its defence is sure.

In the debate on the declaration Clemenceau spoke in the same tone. There were to be no more party men, himself not excepted.

> Who has been more of a party man than I? I have been only too much of one, as I see to-day. . . I shared—and perhaps still share—many of your prejudices, but where I differ from you, deputies of the extreme Left, is that you want to introduce purely intellectual conceptions into the domain of realities—and that is impossible.

The vote of confidence was passed by 418 against 65. Clemenceau was as good as his word. Turmel, a deputy, was tried by court-martial on Nov. 22; parliamentary impunity was suspended by the Senate in the case of Humbert; and Malvy asked the Chamber to appoint a commission to inquire into the grounds for his accusation. Although the accusation had no legal basis, and the rules of the Chamber did not prescribe the procedure in such a case, the Chamber, greatly embarrassed, sent him before the Senate, which, having reinstituted a procedure in disuse since 1875, constituted itself a high court and ordered a supplementary inquiry (Jan. 28). On Dec. 22, at the request of Gen. Dubail, military governor of Paris, the Chamber voted for the suspension of parliamentary immunity for Caillaux by 396 against two votes and 100 abstentions. The accusation of intelligence with the enemy and of a criminal attempt against national security was founded on documents seized during the Bolo case, indicating a singular intimacy between Caillaux and Bolo and Almereyda. The official reports of the French naval and military attachés in Rome also drew attention to the attitude and the defeatist proposals of the former Prime Minister.

On Jan. 14 Caillaux was arrested. Inquiry conducted in the United States had revealed relations with the German Legation at Buenos Aires, at the time of his mission in the Argentine; and from various telegrams sent by Von Bernstorff, German ambassador in Washington (deciphered by the State Cryptographic Dept.) it seemed that Caillaux had spoken contemptuously of the members of the Govt.—Briand excepted. When reporting Caillaux's remarks to Berlin, Von Bernstorff asked his Govt. to instruct the German cruisers to take precautions with regard to the ship on which the French statesman was returning. Finally, in the safe of a Florentine bank rented by Caillaux there was found among the securities a packet labelled "Rubicon," which contained the outline of a scheme to be carried out when Caillaux should again become Prime Minister. This scheme resembles the constitution of the consulate.

These events were discussed in the Chamber, together with the royalist escapades of the *Action Française*, and the resolution passed stigmatised "all proceedings, royalist or other, which tend to divide the country in the face of the enemy." The Socialists and Caillautists voted against the words "or other," assuming that they referred to the "Rubicon." Bolo's trial by court-martial (Feb. 4-14) ended in sentence of death for the ex-pasha for his dealings with the enemy, which included relations with the former Khedive, transactions in America with Von Bernstorff and the payment of German moneys intended for the purchase of French newspapers. He was executed at Vincennes on April 17. To all attacks, direct or indirect, by the Socialists, Clemenceau presented an unmoved front, and claims of every kind—economic, financial and military—were met with the same imperturbability. By a bill passed on Dec. 24 the election was postponed on account of the mobilisation of several million electors. A loan of 10 milliards was liberally supported. Very severe restrictions on the consumption of bread were imposed, and the 1919 class was called up prematurely.

The Russian Defection.—This last measure was necessitated by the defection of the Russians and by Austrian arrogance. Count Czernin, in his elation over Caporetto, boasted that he was fighting as much for the defence of Germany as for the Austro-Hungarian frontiers—"We are fighting for Alsace-Lorraine just as Germany fought for Lemberg and Trieste. I make no distinction between Trieste and Strasbourg." At Brest-Litovsk the Bolsheviks concluded an armistice with Germany.

spite of Russia's undertaking, on Sept. 4 1914, not to nego- ite or conclude a separate peace; they also intimated their tention not to honour the financial engagements of the Tsarist vernment. The French Govt. sent a note of protest, stating at "financial engagements entered into previously in the me of Russia were independent of the changes of government hich had occurred since and might occur again in that country, d that, consequently, they were and would continue to be nding upon those by whom Russia was represented." The cialists now asked for passports for Leningrad (Petrograd) to tempt to dissuade Russia from making a separate peace; but emenceau refused them, because he regarded such a step as seless, dangerous and even unseemly. The signing of the reaty of Brest-Litovsk on March 3 definitely broke the Russian liance.

From the end of Jan. 1918 the bombing of Paris by aero- anes ("Gothas," as they were called) recommenced with fresh igour after a long respite. The raid of Jan. 31 took a toll of 45 lled (31 in Paris and 14 in the suburbs) and 207 wounded; that n March 9, carried out by a dozen squadrons, left 13 dead and 0 wounded. Life in Paris was seriously inconvenienced by the recautions imposed—as the reduction of street lighting, closed utters and the warnings given by sirens. But it was quite nother matter when, on March 23, shell, fired from colossal uns more than 100 km. distant, fell direct on Paris, without ere being at first any clue to their place of origin. Monuments tuated in the danger zones had to be protected by sandbags. n March 29 (Good Friday) a shell fell on the church of St. ervais, at 4 P.M., just as a sacred concert was beginning, killing 5 people and wounding 90 others, of whom several afterward ccumbed. Terrible bombardments at Dunkirk, Calais and heims simultaneously drove the inhabitants into the cellars. he motive behind these attacks was that of terrorising the untry at the moment when the German general staff was unching (March 21) a mass offensive against the British front hich was intended to be decisive. But the morale of the coun- ry was not shaken, any more than was the spirit of the high ommand. Although there were days of acute strain in March nd April Clemenceau never faltered. At the end of March he btained consent from the Allies for Foch's nomination as gen- ralissimo of the armies on the Western Front. He then pro- eeded to tighten food restrictions, ordered three meatless days week, reduced the consumption of paper, etc.

The Czernin Incident.—During these troubled times Teutonic trigues followed fast upon each other. The most sensational f these was that launched by Czernin (April 2), when he boldly sserted in a speech delivered to the municipal representatives in ienna that Clemenceau had asked him, shortly before the eginning of the Western offensive, if he were "prepared to nter into negotiations and on what basis." He went on to in- ist on Austria's loyalty to Germany, and vowed "a terrible engeance" upon the enemies of the Central Powers. Clemen- eau's reply was simply, "Count Czernin lied." By way of etort Czernin recalled the *pourparlers* between Count Nicholas evertera and Count Armand in Feb. 1918. On April 8 Clemen- eau exposed Revertera's "attempt to decoy us into a German eace," and announced "another attempt of the same sort by a erson of much higher rank." Czernin in reply accused Clemen- eau of having wrecked this effort by refusing to enter into nego- iations based on the renunciation of the re-annexation of Alsace- orraine. Clemenceau thereupon disclosed the fact that the ustrian Emperor had with his own hand recorded his willing- ess to agree to "the just claims of France on Alsace-Lorraine."

At this point the Emperor Charles himself intervened with a elegram to William II., in which he declared Clemenceau's tatement to be untrue and proclaimed the "perfect solidarity" etween the two Central Empires. An official communiqué from ienna followed, emphasising this denial. On April 12 Clemen- eau published the Emperor Charles' letter to Prince Sixtus. fter some sharp dispute with the Emperor and Empress, zernin announced that the text of the letter, which had been ntirely private and personal, had been published in Paris in a garbled version. He maintained that the Emperor had written: "I would have used all my personal influence in favour of the French claims with respect to Alsace-Lorraine had they been just claims; but this they are not." Clemenceau again stated the facts, and denounced "les consciences pourris." An embarrassed note from the Ballhansplatz on the 15th then declared the incident closed.

The Decisive Days.—A fortnight later the *Bonnet Rouge* trial opened before the court-martial. Although Almereyda, the principal conspirator, was dead, the evidence revealed by the inquiry was sufficiently serious for sentence of death to be passed on Duval—who had received over 1,000,000 fr. from a Mannheim banker named Marx—and for several of his associates to be sent to penal servitude. The Socialist party, of which the anti-war section had won a majority in the national council of the party, agitated in vain for a "white peace"; the threat to refuse military credits left Clemenceau unmoved. Only for an instant at the end of May, when a new offensive brought the Germans up to the Marne from Château-Thierry to Dormans, did he consider the idea of evacuating the Government and a portion of the population from Paris. He had become as military-minded as—if not more so than—the soldiers themselves. Paris was a city like any other, and it seemed to him a wise precaution to abandon the capital as in 1914. But the circumstances were very different. After four years of fierce fighting the occupation of Paris by the enemy would have appeared as a German triumph in the eyes of the world at large, and the consequences, both material and moral, would have been incalculable. The evacuation project, which had been kept secret, was therefore opposed by the President of the Republic and the presidents of both Chambers. In a special council at the Elysée, at which other persons besides ministers were present, it was finally decided that the Govt. should stay in Paris and that the decisive battles should take place in front of and not behind the capital. On June 11 a successful counter-attack by Mangin's army threw back the Germans some kilometres, and, on July 18, Foch opened the great offensive which was to continue until the Armistice. Czechoslovak and Polish legions, formed of deserters and volunteers, fought side by side with French troops.

On July 16, before the Senate, sitting as a high court, Malvy was accused of complicity "in treason which threatened the very existence of the country." The Senate, however, rejected the charge of treason, on Aug. 6, unanimously but for two votes, and that of complicity in communicating with the enemy by 125 votes against 36. Senator Etienne Flandin then made the subsidiary charge: "Is Malvy guilty of having committed the crime of *forfaiture* while residing in the territory of the Republic and during the discharge of his ministerial functions within the last 10 years?" At the following session this accusation was definitely formulated. It was directed against the minister's attitude towards Almereyda and certain other anarchists. On Aug. 6 the Senate declared Malvy guilty of *forfaiture* by 101 votes against 81, and condemned him to five years' banishment, but without civic degradation. There remained the Caillaux affair—by far the most serious. Was Caillaux to come before a court-martial or the High Court? The Govt. decided that if the case were one of intelligence with the enemy the court-martial should deal with it, but if it were that of crime against the security of the state it should come before the High Court. The latter solution was adopted, and the Senate met for the purpose on Oct. 29 and found that there were grounds for instituting an "instruction," the affair being thereby indefinitely adjourned.

The Armistices.—Beaten by the Govt., the Socialists confined themselves to protests. At their National Congress in Oct. the advanced group, headed by Longuet, carried the day by 1,528 votes against 1,212 and 181. Cachin was made editor of *l'Humanité* in place of Renaudel. But the people remained indifferent, being concerned only with the retreat of the German armies, the crumbling of the Bulgarian front, the abdication and flight of the Tsar Ferdinand, the progressive reoccupation of the devastated departments and the entry of the Belgian Army into Bruges. Under these auspices was launched on Oct. 20 the fourth great loan, the Liberation Loan, which realised 22 milliards. On the night of Oct. 30–31 Turkish plenipotentiaries signed an armistice with Adm. Calthrop at Mudros; on Nov. 3 the Austro-Hungarian armies signed an armistice; the break-up of the old Dual Monarchy was already far advanced.

A far-reaching problem now confronted the Allies. Was it wiser to conclude with Germany the Armistice which her desperate Govt. had asked from President Wilson, or to force the German armies to capitulate, and so enter Berlin? French ruling spirits were divided. Foch held that "war is only waged for its results, and, if these results are obtained by the Armistice, no one has the right—the aim being achieved—to cause one more drop of blood to be shed." The generalissimo knowing nothing of the developments of the revolution overshadowing Germany believed that it would still take several months to throw back the enemy across the Rhine. The conditions of the Armistice were therefore discussed, first at Senlis by the military delegates, then in Paris and Versailles among the heads of the Govt. and the foreign ministers of the Allied and Associated Powers, the discussions being based exclusively on military considerations. The statesmen agreed unreservedly to the proposals of the military council at Versailles. Many of them, at that moment, were so far from thinking the proposed conditions too mild that they feared the German plenipotentiaries would refuse certain exceptionally severe clauses, such as the surrender of the fleet and the fortresses of Alsace-Lorraine. The Germans, however, terrified by the prospect of invading enemy armies who would be tempted to avenge themselves for the abominations committed in Belgium and France, signed all the conditions on Nov. 11.

The proclamation of the Armistice, accompanied by the ringing of bells, led to scenes of enthusiasm that day in the streets and in Parliament. The two Chambers proclaimed that "Citizen Clemenceau and Marshal Foch have deserved well of their country." On the following day Foch was elected a member of the Academy of Sciences, and on the 21st the *Académie Française* elected Foch and Clemenceau, having previously elected Joffre (Feb. 14). Clemenceau, a doctor of medicine, was elected a member of the Academy of Medicine on Dec. 3. Finally the *Académie des Sciences Morales* opened its doors to Marshal Pétain, and the Beaux Arts elected Gen. Castelnau. Only the Socialists, while joining in the general rejoicings, professed an interest in the Russian revolution which was hardly justified in view of Russia's behaviour at the end of the War. The motion drawn up by the "Permanent Administrative Commission" of the party was disavowed by members of the minority, who announced their determination not to allow the methods even of revolutionary socialism to be confounded with Bolshevik practices, which did not allow universal suffrage to function. The French authorities now took possession of Alsace-Lorraine. On Nov. 17, in front of the statue of Strasbourg on the Place de La Concorde, from which the emblems of mourning had at last been removed, a magnificent ceremony was staged. At Metz Pétain was presented with his marshal's bâton, and on Nov. 25 the victorious troops entered Strasbourg amid scenes of frenzied enthusiasm. The War was over; it remained to "win the peace."

THE PEACE

The Armistice of Nov. 11 contained no political clause. It was assumed that, as was customary, some of the essential political conditions would be settled in peace preliminaries before the final treaty was signed. Had preliminaries been so arranged as to coincide with one of the three renewals of the Armistice, it should have been possible to take immediate measures for ensuring the position of those regions whose lot was to be changed—notably Poland, Upper Silesia and the Baltic States—where such measures were of the first importance. Certain opinion in France urged that this should be done. But for reasons that are still unexplained, no steps were taken to arrange such preliminaries, which, if arranged a few weeks after the military capitulation—so it was agreed—would have enabled the Allies to insist on all the points that seemed to them advisable. The end of the year was spent in rejoicings. The King of the Belgians and the King of England paid official visits to Paris, and President Wilson, before settling in Paris for the conference, visited England and Italy. When the conference opened on Jan. 18, Germany was more or less reassured, and on vital points Clemenceau was no longer in position to impose his views. He had to consult with President Wilson and Lloyd George. Indeed, in consenting to the form of procedure—Council of Ten, Council of Five, Council of Four, absolute secrecy, rigorous censorhsip of diplomatic indiscretions—he automatically forfeited the support which would have been gladly accorded to him by the representatives of the smaller powers, by Parliament and by influential publicists. Although both the President of the Republic and the presidents of the two Chambers disapproved of these "cellar negotiations," the system was maintained till the end. The conference only met in full open session to register preconcerted decisions. Thus Clemenceau, although he made spasmodic attempts at resistance, saw himself forced to concur in certain solutions that were contrary to his intentions.

This was particularly the case with the Rhine frontier. In common with the military authorities, many university men and several publicists, Clemenceau would have constituted the Rhine France's military frontier and formed the German countries lying between that river and the political frontier into an autonomous state. He was not even able to obtain the restitution of Saarlouis and Landau which had been severed from France by the Allies of 1815, in spite of their formal engagement (signed on March 13 1815, after Napoleon's return from Elba) to preserve intact France's frontiers of May 30 1814. He committed the imprudence of offending President Wilson by scoffing at the projected League of Nations, and prevented M. Bourgeois from bringing forward the plan of a league drawn up by French specialists. Surrounded by colleagues chosen from among his immediate circle, he was not amenable to any advice or suggestion and was neither wise enough to limit his original demands to what might be accepted nor to exact effective compensation for his successive concessions. To crown his misfortunes, he was wounded (Feb. 18) by three shots from a revolver by an anarchist named Cottin. When negotiations were resumed on March 14, after his recovery, decisions, contrary to his wishes, had been taken. France was only to have Alsace-Lorraine; the Inter-Allied military occupation of the left bank of the Rhine was fixed for 5, 10 or 15 years according to the zone; Germany was to renounce all rights in Morocco; power was taken to regulate the zones of Savoy; and Great Britain and the United States were to give a military guarantee against unprovoked German aggression, Britain's guarantee being dependent upon the ratification of that of the United States by the Senate in Washington.

The amount to be exacted for reparations for the terrible damages caused by the enemy was not fixed; a Reparations Committee was set up to settle it and to draw up the conditions of payment. Germany was to pay down on reparations account a sum of 20 milliard gold marks before May 1 1921. It was assumed in France—and Mr. Lloyd George's speeches in England appeared to justify the assumption—that Germany would pay for everything. Clemenceau and Klotz were under that illusion, for they brought in a bill passed on April 17 1919 by which those who had suffered damages were enabled not only to claim the price of their possessions at a pre-War valuation, but also the cost of reinstalment or reconstruction, taking into account the rise in prices since 1914. This arrangement was fated to bring about a financial catastrophe. Some hundred milliards had to be paid out on this score, and (in the event) Germany was to go bankrupt to evade payment. It was the same with similarly lavish promises of demobilisation premiums, pensions and allowances to the military victims of the War and their dependants; these had been made on the conviction that Germany would pay, but they made another deep hole in the budget. Other holes were made by the extravagant decision to y in at the rate of 1·25 fr. all German marks left in Alsace-raine (quoted then at 0·70 fr.) and buy back in dollars a large sum the American war stores which, if sold direct by American stores department, could have been usefully sorbed by the population without involving the Treasury. ese rash measures were to react disastrously on the whole of national life.

The Socialist Movement.—The propaganda carried on by rman Socialists infected their French comrades, who had n roused by the acquittal of the assassin of Jaurès on March 1919 at the assize court of the Seine, and were to be appeased ther by the passing of the Eight-hours' Day bill by both ambers at the end of April nor by the maintenance of the ce of bread below cost price. On May 1 they proclaimed a ike, and proceeded to demonstrations which led to the dis-ssal of several Socialist leaders holding government posts. e disturbances lasted all through the spring. The *confédéra-n Générale du travail* itself was powerless to maintain dis-line among its adherents; it alternately curbed their turbulence d yielded to their demands. When the peace treaty was being cussed with the German plenipotentiaries and the Allied mili-y intervention against the Bolsheviks was proceeding, labour ubles became more marked. But the public faced the situa-n with such firmness that the general strike arranged for ly 21 miscarried. Clemenceau was nevertheless awkwardly uated in the Chamber and had to replace the Food Controller ret by Noulens.

The Versailles Treaty.—After several crises, particularly with spect to the question of the Adriatic and Danzig, the peace nditions, comprising 440 articles and numerous annexes, were remoniously presented to Graf von Brockdorff-Rantzau, the rman plenipotentiary. The counter-proposals made by the rman delegation provoked lively discussion among the Allies, veral important modifications being supported by the British vernment. Towards the middle of June the Allies at last me to an agreement to maintain almost in its integrity the xt of May 7, the only really significant modification being the bstitution of a plebiscite in Upper Silesia for the annexation re and simple of that province to Poland. On June 16 the ial text was submitted to Brockdorff-Rantzau with the warn-g that it must be accepted without reservation within five ys. He resigned, and an extension of two days was granted. the 23rd a new German Cabinet with Gustav Bauer at its ad declared itself willing to sign, and on the 28th—the anni-rsary of the Serajevo murders—MM. Hermann Müller, Bell d von Haniel, the German plenipotentiaries, in the Hall of irrors at Versailles in which the German Empire had been pro-aimed in 1871, signed the treaty of peace which established the rritorial integrity of France, celebrated the triumph of right er might and destroyed Germany's supreme effort to achieve world hegemony. The treaty by which England and the nited States agreed to assist France in case of unprovoked attack as signed by Lloyd George and President Wilson the same day.

The treaties, taken as a whole, certainly were imposing, and arked an epoch in history. All the same, the French nation perienced a shiver when the clauses became known in detail. was realised, as Poincaré said, that the peace was to be *une éation continue.* Many serious problems were left unsettled. everal plebiscites, which would normally have been taken be-een peace preliminaries and the conclusion of the treaty, were ljourned until a time when—the demobilisation of the Allied mies having been effected—there would be no means of en-ring a true ballot. No precise sanctions had been stipulated the event of the non-execution of the treaty by Germany. he League of Nations Covenant, was held by French opinion be vague as to the principal obligations of its members. The rms were drawn in language permitting the contracting Gov-nments to interpret it in favour of evading liabilities. In short, became plain to the French that the Versailles Treaty would be rried out to their advantage only if the Allies, especially reat Britain, wished it. Except for Alsace-Lorraine they had received nothing but promises; their right to exact the fulfilment of Germany's engagements without the assent of all the Allies, was contested. The ratification of the treaty (Aug.-Sept.) therefore aroused violent opposition in the Chamber. Men like Louis Marin and Franklin-Bouillon called for its rejection. To reassure the deputies the Finance Minister announced, on Sept. 5, that Germany would put down a round sum of 450 milliards. In the end the ratification was agreed by only 372 votes against 52, with 73 abstentions. By the Senate, in Oct., it was approved without difficulty. But very soon it became known that the American Senate refused to ratify the Treaty of Versailles and the Treaty of Guarantee, and that, in consequence, the British guarantee disappeared. The most stupefying discovery was, however, that during the peace year of 1919 military expenditure exceeded that of 1918 with its fierce fighting, and that the National Debt had risen during the 12 months of peace from 170 to 218 millards. Under the shock of these affairs the country embarked on the election.

The Elections.—It was indeed time to return to normal constitutional life. All the elective assemblies had to be renewed, having outlived their legal term. The parliamentary elections took place on Nov. 16 according to the system adopted by the Act of July 12 1919: *scrutin de liste* according to department, with proportional representation in cases where none of the lists showed an absolute majority, together with the support of 25% of the electors on the roll. It was at first intended to maintain the political *union sacrée* by including Clemencistes, Liberal, Radical, Radical-Socialist and Moderate Socialist candidates on the same list; but the unified Socialists repudiated the union, and the Moderates—such as Herriot, Viviani, and Painlevé—separated from the Coalition after agreeing to it. Lists were accordingly framed as follows: the *Bloc national* including all moderate candidates—as, for instance, from Millerand to Maurice Barrès in Paris; and lists for the Unified Socialists, Radical Socialists and Independents of different categories.

The *Bloc national* had as its programme Millerand's Paris speech of Nov. 7 at the Ba-ta-clan hall. This speech denounced the class struggles, indicated the need of strengthening the Executive, of adopting a broader basis for the nomination of the President of the Republic, and for the constitution of the Senate. Clemenceau for his part made a great anti-Bolshevist speech at Strasbourg. At that moment, when demobilisation was complete and the opinions of the soldiers an unknown quantity, Bolshevism was thought to be the chief danger. In the beginning of Nov. a general strike was attempted. The newspapers were especially affected and, from Nov. 11, they ceased to appear; but they agreed between themselves to publish one organ in common, the *Presse de Paris*, in which space was reserved for a brief political article from each paper. This expedient was well received by the public. Soon the *Presse de Paris* appeared twice a day, corresponding to the morning and evening issues. The *Bloc* won the elections, and the new Chamber was made up of 56 Unified Socialists, 5 dissenting Socialists, 28 Republican Socialists, 129 Radicals and Radical-Socialists, 114 Republicans of the Left, 138 Progressives, 15 Liberals, 74 Conservatives and 3 adherents of the *Action Française*. The Bolshevist candidates were swept away; even in a suburb of Paris the list containing the names of Longuet and Sadoul was lost.

The municipal elections of Nov. 30 gave the same results. From the outset the Moderate elements carried all before them, not only in Paris but in many towns where they had formerly been in a minority as, for instance, at Toulouse. The check to the revolutionary parties was emphasized by the end of the newspaper strike on the same day. On Dec. 14 *conseils généraux* and *conseils d'arrondissement* were elected. Here the Left was more successful in holding its seats, based as it was on solid local organisations, and was able to recover lost ground on the senatorial elections (Jan 12), in which the prefects exercise considerable influence. Only 26 seats were lost by the Radicals, and Léon Bourgeois was elected president of the Senate by 147 votes against Antonin Dubost (with 125), the retiring president, of much the same political tendency.

The Presidency of the Republic.—Opening on Dec. 8, the Chamber had no important affairs to deal with before proceeding to elect a successor to Poincaré, whose seven years' tenure expired on Feb. 17 1920. The only outstanding event of its short session was the declaration of the Alsace-Lorraine deputies, whose entry into the Palais-Bourbon had been made an impressive ceremony. After recalling the protests of their ancestors against the Treaty of Frankfurt the representatives of the two reannexed provinces recorded the fact that no protest had been raised during the elections against the Treaty of Versailles. "France," they said, "has obtained a unanimous vote at the genuinely plebiscitary elections of Nov. 16."

On the choice of the future President of the Republic opinion was divided. Though he desired election, Clemenceau had not come forward openly. Deschanel stood as candidate. In spite of Clemenceau's disturbing antecedents, his popularity as victor was so great that the choice would have fallen upon him out of gratitude rather than from confidence in his political wisdom, had he not wounded the sensibilities of a large number of the *bloc national*. He had steadily refused them the satisfaction of re-establishing diplomatic relations with the Vatican, although they had pledged themselves to their constituencies to demand it. Moreover, while declaring that he would in no case remain Prime Minister, he showed a marked preference for former ministers ousted by the *bloc*. He also retained among his most intimate colleagues certain men who inspired justifiable suspicion. Unmoved by the insistence of the deputies, who were bent on seeing him rewarded by the supreme magistrature of the state, he refused to make any concession. Indeed, he openly announced his intention of reigning at the Elysée as the head of the Govt. and not as the Constitutional head of the state, and thus alienated many of the electors. On the eve of the Congress at a preliminary meeting, Clemenceau obtained only 389 votes against Deschanel's 408. Consequently he refused to stand, and Deschanel was elected by 734 votes out of 888 (Jan. 17 1920). The Cabinet resigned next day.

As leader of the *bloc national* Millerand was called upon to form the new Cabinet, which was constituted (Jan. 19) as follows: Millerand, Foreign Affairs; Interior, Steeg; Public Works, Le Trocquer; François-Marsal (a banker, not a member of Parliament), Finance. Poincaré was appointed President of the Reparations Commission. On Jan. 22 the Chamber passed a vote of confidence by only 272 votes against 23, half the members having abstained from voting in token of their resentment at having a Radical (Steeg) appointed to the Interior. But the majority rose to 481 against 70 on the 30th, after explanations by the Prime Minister.

Strikes and the Caillaux Case.—The internal situation did not realise the expectations inspired by the happy ending of the War. The *confédération générale du travail*, carried away by the masses it was supposed to control, instigated a strike of railwaymen in the spring, which was followed by miners', dockers' and seamen's strikes. None of these were successful, but they served to aggravate the industrial crisis caused by the rise in prices. That communist ideas were gaining ground in the Labour world was apparent at the Socialist Federal Congress of the Seine (Feb. 22), when the extremist motion put by Loriot, after an exchange of recriminations, was carried by an enormous majority. It looked as if the wave of revolution would sweep all before it. The disturbances coincided, not fortuitously, with the Caillaux case, which took its course before the Senate, constituted a high court, from Feb. 20 to April 23. Caillaux was condemned to three years' imprisonment and ten years' loss of civic rights; for five years his place of residence would be strictly that indicated by the Govt., and he was ordered to pay the costs of the trial. He was found guilty of corresponding with the subjects of an enemy country since the declaration of war, and notably in 1914, 1915, 1916 and 1917, both in France (especially in Paris) and abroad, the said correspondence having furnished the enemies of France with information detrimental to the military or political situation of France or her Allies—(Article 78 of the Penal Code). The high court admitted extenuating circumstances, and dismissed the charge of high treason. A Caillaux had already been detained in preventive arrest for two years and four months, he was released.

Relations with the Vatican.—Relations with the Vatican which had been suspended since 1904, were now re-established in accordance with the wishes of the majority in the Chamber and in the country, by a bill granting the necessary credit for setting up an embassy to the Holy See. Without waiting for the passage of the bill Millerand sent a *chargé d'affaires* to the Vatican to prepare for the resumption of relations (March 1920). The bill was not actually passed until Nov. 30 by the Chamber (379 votes against 109) and not until Dec. 16 1921 by the Senate (174 against 129). The Senate, with its Radical majority and anti-clerical traditions, bristled instinctively at any projects which looked like an infringement of laicisation, and the situation was further complicated by the problem of voluntary parochial corporations (*cultuelles*), which dated from the Act of Separation between Church and State (1905). The Holy See, having refused to acknowledge the separation, had forbidden the creation of *cultuelles*. Even the simple mutual ecclesiastical associations which several of the bishops desired to found as retreats for aged priests came under the ban.

The position of the French Church was therefore ill-defined and precarious, and Benedict XV. was as anxious to put an end to it as was the French Government. Since 1905, however, all the bishops had been nominated in Rome from among candidates intransigent towards the civil power, and the Pope was surprised to find, on the occasion of the Joan of Arc canonisation festival (May 16 1920) when Hanotaux represented the French Govt., that they were strongly opposed to the bill. Those of them who had come to Rome delivered a collective letter to this effect to the Pope. But as Jonnart had been appointed ambassador to the Vatican on May 16 1921, the papacy responded by the appointment of a Nuncio, Mgr. Cerretti, who arrived in Paris on Aug. 6. In spite of all efforts on both sides the question was still unsettled at the time of the Pope's death (Jan. 23 1922). Two years later, Pius XI., his successor, promulgated the Encyclical of Jan. 18 1924, by which permission was given to organise, by way of an experiment, "diocesan" corporations—that being the name chosen in place of *cultuelle*, as placing emphasis on the absolute power of the bishop over the corporation.

Execution of the Versailles Treaty.—The application of the treaty, both at home and abroad, was the chief concern of Millerand's Cabinet. The reconstruction of the devastated regions swallowed up vast sums which Germany—contrary to public expectation—failed to produce. Considerable sums also went in restocking the country with essential materials, above all, coal. The British Govt. exacted payment for British coal at a decidedly higher rate than the home prices. Since 1919, too, it had done away with common accounts. During 1920 France had to borrow nearly 38 milliard francs, thus raising the budget to close on 20 milliard (as against 5 milliards in 1913). These sacrifices were not compensated by other facilities from the Allies. In successive conferences—held in London in Feb., at San Remo in April, at Hythe in May and at Spain in July—Millerand obtained nothing but verbal expressions of sympathy although he gave way on some points of the treaty to the advantage of Germany. At San Remo, in return for the definite abandonment of Mosul, which came into the sphere of French influence as defined by the convention of May 16 1916 (Sykes-Picot Agreement, *see* EUROPE; INTER-ALLIED DIPLOMACY), France was presented with those shares in the Turkish Petroleum Co. (25%), which had formerly belonged to the German Government. Lloyd George felt obliged to devote himself principally to the economic recovery of Germany, which he assumed to be a necessary condition for the development of English markets in that country, and for the maintenance of European peace. Millerand had to fight some hard diplomatic battles on this subject with the Cabinet in London. He found himself in collision with Lloyd George on the Polish question when the Bolsheviks invaded the young republic in August. Lloyd George wanted the Polish Govt. to abandon Warsaw;

llerand retaliated by recognising Gen. Wrangel's government South Russia, and by sending a group of French officers to ırsaw under Gen. Weygand's orders. The friction thus caused s not dispelled by the retreat of the Bolshevik armies, for ile London was pessimistic as to Poland's future, Paris re- ded Poland's independence as the keystone of the new Europe. ance complained that, in taking up her mandate over Syria ording to agreement, she was thwarted by British agents.

A deplorable accident occurred to complicate the situation. the night of May 24, when making an official journey, the sident of the Republic fell from his sleeping-car on to the ıway line. Although not seriously injured he was so badly ıken that he was forced to rest from his work, and resigned on ot. 16, bidding farewell to the Chamber in a moving speech. Sept. 23 Millerand was elected President of the Republic by ; out of 892 votes. In offering himself as a candidate he had ıounced his intention of making more effective use than his decessors had done of the prerogative assigned to the head the state by the constitution. After election he defined his ws with greater emphasis, and, once installed at the Elysée, acted in conformity with his programme.

The Leygues Cabinet.—The changes in the Ministry necessi- ed by Millerand's election as First Magistrate were reduced a minimum. Georges Leygues became president of the Coun- and Minister of Foreign Affairs and the other Ministers re- ned their portfolios. This Cabinet had a brief and troubled . The *Bloc national* adopted an even more exacting and fiant attitude towards it than towards the preceding one. ıdré Lefèvre, Minister of War, resigned on Dec. 6 because he s not allowed a free hand in securing German disarmament. Jan. 12 1921, on the eve of a London conference and in con- uence of an interpellation by Bonnevay, the Chamber over- rew Leygues by 447 votes against 116 on the pretext that it nted no "negotiations in the dark." Nevertheless Leygues s in no way to blame; on the contrary, he had re-established friendly relations with the states of the Little Entente which d been upset by the action of the Quai d'Orsay the year before.

Briand's Cabinet.—Briand now formed a Cabinet in which he ld Foreign Affairs, giving Justice to Bonnevay, War to Bar- ou, Finance to Doumer and the Liberated Provinces to ucheur. He was well received by the Chamber on Jan. 20 d obtained a vote of confidence by 462 votes against 77. The ter-Allied conference for the settlement of reparations, which d been planned in London, was held in Paris on Jan. 24–8. was with difficulty that an agreement was reached; Germany's yments were spread over a period of 42 years, the sanctions be applied in case of non-payment being left vague.

They were to be as those securing German disarmament—*i.e.*, olongation if necessary of the occupation of the Rhineland; e seizure of German customs; the occupation of new territory, cluding the Ruhr; the application in Rhineland of customs ities or others. In any case, as these sanctions were not to nction automatically, negotiations would be necessary each ne they were to be applied. From Feb. 3 to 9 these questions ere discussed by the Chamber which finally approved the overnment's action by 363 against 114. Germany having by is time announced her inability to meet her immediate obliga- ons, a conference was held in London on Feb. 20, as the result which an ultimatum was sent to Germany (March 3) stipulat- g for: the occupation of Duisburg, Ruhrort and Düsseldorf, levy on the sales of German goods in the Allied countries and e establishment of a customs frontier on the Rhine if Germany ould persist in her opposition. These sanctions were to be plied automatically if Germany did not send a favourable ply by March 7. The reply was not forthcoming, and the lied troops proceeded to a joint occupation of the three wns named. These events were discussed in the Chamber on arch 15–7 and a vote of confidence was passed by 490 votes ainst 69. Meanwhile, the vote on the budget of 1921 had at st been taken, on April 30, after four *douzièmes provisoires.* is time the budget exceeded 21 milliard francs.

On April 30 a new conference was called in London to study "the situation created by the total failure of Germany to fulfil the dispositions of the Versailles Treaty as regards disarmament, the punishment of guilty persons and the reparations." The Reparations Commission had fixed Germany's total payment at 132 milliards of gold marks. A sum of 12 milliards was due and could be exacted on May 1. It was not paid. The conference agreed to warn Germany to meet the obligations named by the commission within 12 days, failing which the Ruhr would be occupied. There was nevertheless great opposition to this form of sanction in England; the French Govt., on the contrary, was acting under the pressure of public opinion. It was decided, on May 3, to mobilise the 1919 class, recently authorised, and the *Conseils généraux*, then sitting, voted for the most part in approval of this attitude. On May 5 there appeared the official text of the Allied declaration, which announced the occupation of the Ruhr on the 12th, failing the submission of Germany. But on the 11th Germany capitulated. The Chamber, on its return from recess on May 10, held a debate on this whole affair, the upshot of which was a fresh vote of confidence (390 votes against 162). The governmental majority was even larger on June 3, when a debate was held on the advances made for damages in the liberated regions (457 votes against 67). When the Chambers rose on July 12 the Inter-Allied Conversations were resumed, taking place in Paris (Aug. 16) for the settlement of Belgian priority and the costs of occupation and at Wiesbaden (Aug. 27) on deliveries in kind. The Conversations coincided with important negotiations of another description.

The Angora Convention.—With respect to Turkey, Briand held views which were not shared by observers of the Eastern question. He believed Turkey to be both powerful and sympathetic to France, and instead of endeavouring to consolidate the Treaty of Sèvres (Aug. 10 1920), by which Eastern affairs had been settled with due regard to the just claims of the Christian populations affected, he listened to the Kemalists. Acting under the influence of the Hellenophobes and of the unfavourable impression he had formed of British agents, whether in Syria or the neighbouring provinces, he sent out Franklin Bouillon—a pro-Turk and anti-English deputy—to Angora with instructions to make a special convention designed to put an end to disputes on the Turco-Syrian frontier. On Oct. 20 Bouillon signed an agreement at Angora which made exorbitant territorial and political concessions to the Turks, and contained additional clauses which were even more questionable. The text was kept secret. It leaked out nevertheless that France stood committed by one of the annexed clauses "to endeavour to solve in a friendly spirit (*esprit de cordiale entente*) all questions dealing with the independence and sovereignty of Turkey." Yielding to his Turcophil obsession, Bouillon had concluded something in the nature of an alliance rather than agreement of liquidation. He had even promised the Turks war material, which he requested the high commissioner in Syria to deliver to them; but this called forth such vigorous protests from those who were *au fait* with Eastern affairs in Paris that the material was stopped. Briand hastened to have the Angora agreement ratified by the President of the Republic without submitting it to the Chambers, which had met again on Oct. 18. On Oct. 28 he left for the conference on naval disarmament that was about to open in Washington.

The Washington Conference.—In spite of repeated warnings from well-informed personages, Briand insisted on going himself to Washington as France's representative, his idea being to act as arbitrator between Britain and the United States—assumed to be divided on the question of reducing naval armaments. He made one great public speech which for a moment gave him the illusion of success; but, as might have been foreseen, the British delegation came to an agreement with the American Govt. without considering French interests and even using arguments against them which were strongly challenged.

By the Washington Convention the French Navy, reduced by the War to a position in the third rank, was condemned to be placed on a still lower level. Although the state of her shattered finances prevented France from resuming her former position as a naval power, public opinion was hurt by an agreement which gave an official seal to the naval preponderance of friendly Powers which had profited by circumstances to assert their dominion over the seas. Briand's authority was undermined, and it was not long before another negotiation compromised it still more.

The Cannes Conference.—Returning from Washington in Dec., Briand departed almost immediately for London, where he was to confer with Lloyd George on the subject of the payments due on Jan. 15 and Feb. 15 1922 which Germany declared herself unable to meet in full. But instead of insisting on the settlement of this particular matter he allowed himself to be persuaded into calling a meeting of the Supreme Council at Cannes for Jan. 6. In the interval he found himself placed in an awkward position in the Chamber with regard to the Industrial Bank of China, a concern which was in difficulties and had been guilty of irregular transactions. One of the administrators, Senator André Berthelot, was the brother of Philippe Berthelot, secretary-general of the Ministry for Foreign Affairs. At first Briand tried to exonerate Philippe Berthelot, who was accused of having improperly used his influence to shield the bank; but he finally gave up the attempt and, on Dec. 27 1921, accepted his resignation. On the following day his majority in the Chamber was only 361 against 238.

His fall was brought about by differences over the conference at Cannes. As Premier, Briand was aware that President Millerand, with a majority of the public behind him, was profoundly opposed to the recognition of the Soviet Republic and to the modification of the French claim on Russia for the repayment of loans. But at Cannes, Briand agreed to a European Conference at Genoa, with a wide programme, to which Russian representatives were invited. Simultaneously, he was negotiating with Lloyd George the scheme for a pact designed to replace the stillborn convention of June 28 1919, which had been made void by nonratification in the United States. In Paris, the British guarantee, though almost identical with the former treaty, was regarded with suspicion because first, it contained no military convention, and secondly, it was accompanied by a memorandum which laid down a common policy for Britain and France, so limiting French liberty of action in Europe. Briand was bitterly accused of yielding to Lloyd George's persuasions and his policy was denounced as "cinematographic." The treaty made Great Britain responsible for resisting, with France, any violation by Germany of the military and naval safeguards of the treaty of Versailles but it was held that these guarantees were insufficient. Feeling ran high, in the Senate particularly. The Commission on Foreign Affairs, over which Poincaré presided, dispatched a telegram to Briand, reminding him of the indispensable conditions of an agreement, and the President of the Republic took the further step of requesting his urgent return to Paris. After a conversation at the Elysée and without waiting for a motion by the Chamber, to which he offered vague explanations, he gave in his resignation on Jan. 12 1922.

The Poincaré Ministry

In response to an almost universal public demand President Millerand appealed to Mr. Raymond Poincaré to deal with the crisis. He formed a Ministry on the 15th. He took Foreign Affairs, giving Justice to Barthou, Finance to de Lasteyrie, War to Maginot and Public Works to Le Trocquer. The heads of the Radical party had refused to join the new Ministry. Warmly welcomed by the public, Poincaré gained a vote of 434 against 84 in the Chamber on his ministerial declaration which was unusually firm in tone. He had to take a firm stand at Genoa without delay. He might have stopped the meetings and dissociated himself from the policy agreed upon by his predecessor without the government's consent. This would have meant a quarrel with Lloyd George. He preferred, however, to let the meetings fixed for the 10th April proceed, and went over to Boulogne for a talk with Lloyd George on Feb. 25. The only result of this somewhat chilly interview was a banal communiqué affirming the Entente between the two Governments.

The Genoa Conference.—At Genoa, where Barthou was i charge of the French delegation the Entente was only preserve with difficulty. Lloyd George who had, at the time of the Peac Conference, talked of inviting the Bolshevik delegates to Prinkipo, now made marked advances to them on the pretext tha Russia's collaboration was necessary to the restoration of norma life in Europe. But the inopportune publication of a Russo German treaty, concluded at Rapallo under the very nose of th conference, made it plain to all that the Germans and the Bolsheviks were also concerned with their own interests, whateve the rest of the world might think about it. At the Genera Council of the Meuse, Poincaré, who was president, made speech in which he reiterated his intention to allow no reductio or limitation of the claims and guarantees of France recognise by the Treaty of Versailles. The Genoa Conference, which ha been marked by various tragic-comic incidents, ended its futil existence on May 19. The Chamber signified its approval of th Government by 436 votes against 96. During the Conference th President of the Republic had made an extended tour in Morocc and Algeria.

Meanwhile the Chamber had been working at the reorganisation of military service to meet post-War conditions. Afte lengthy debates a bill was passed (June 29) by 365 votes agains 205, reducing the period of active service to 18 months and prescribing the incorporation of the 20-year-old recruits in two contingents so that there would always be at least two half-classe with the colours. This bill was not passed by the Senate unti the following winter. It came into force on April 1 1923.

The Eastern Conflict and Reparations.—In Aug. a fresh conference held in London failed to reconcile the English view tha Germany should be allowed a moratorium without correspondin compensation, and the French view that this should only b granted in return for a share of 60% in certain German industries, the establishment of customs depôts at the exits from th Ruhr, the collection of taxes in the occupied territories and th exploitation of forests, and of the Ruhr mines. At this momen an Eastern tragedy broke in upon the situation. The reorganise Turkish Army, set free on the Syrian side, broke the exhauste and badly led Greek Army on the Afiun Qarahisar front o Aug. 26, reconquered Asia Minor, took Smyrna on Sept. 8 and advanced on the Straits, occupied at Chanaq by Anglo-French contingents. Poincaré, unwilling to expose the French contingen to conflict with the Turks, gave orders for it to cross to th European side—to the surprise and indignation of many Frenchmen. A sharp crisis with Lloyd George ensued; he had sympathized with the desire of Greece to achieve a national destiny in the near east.

Lord Curzon went to Paris Sept. 19 to smooth the trouble. On Sept. 23 the lines of a new treaty of peace with Turkey were agreed, with the participation of Count Sforza, and after a second visit to Paris by Lord Curzon an armistice was signed a Mudanya (Oct. 11), when it was agreed that the plenipotentiaries authorised to settle the Eastern question should meet a the end of November. But the differences of opinion betwee the Cabinets of Paris and London, both on the measures to b adopted with regard to Turkey and on the subject of reparations persisted in spite of the resignation of Lloyd George and th advent of the Bonar Law Cabinet at the end of October.

French politics were at this time entirely dominated by th question of reparations, that is to say the execution of th "scale of payments" fixed in London in May 1921. Opinio became more and more irritated at seeing Germany devote th sums which she was under obligation to pay to the Reparations Commission to the completion of her industrial equipment, th extension and improvement of her communications, and extravagant domestic expenditure. Poincaré's protests were formally approved by the Chamber (with nearly 500 votes) and by a almost unanimous Senate. In London, on the contrary, th first consideration was that Germany's internal economy shoul not be disturbed. Bonar Law's attitude towards France was more amicable than that of Lloyd George, but the solutions which he proposed were hardly more favourable. In short, he ught rather to pursuade Poincaré to renounce for an indefinite eriod his claim for payment than to force Germany to pay. hen again the old spirit of rivalry between the chancelleries ersisted, diplomacy being untouched by the fraternity of arms. rance's efforts to secure the execution of the peace treaties were t down to imperialism. The London proposals were impreg- ted with distrust of France. Thus, at the Lausanne negotia- ons as in the Paris meetings, friction continued.

The Ruhr.—On Nov. 14 Wirth, the German Chancellor, nounced Germany's inability to pay for an indefinite period, a eclaration repeated by his successor Dr. Cuno. Outrages were ommitted at Stettin, Passau and Ingolstadt against Allied ficers. On Dec. 9 Bonar Law, Poincaré, Theunis and Mussolini et in London to discuss a new note from Cuno, while Lloyd eorge, at the same moment, made a violent attack on France in e United Press. Unable to reach agreement, the Conference oke up, and another meeting was arranged for Jan. 2 in Paris. oincaré secured the approval of the Chamber on Dec. 15 by 52 votes against 76, and of the Senate (carried unanimously) Dec. 21. On the 27th the Reparations Commission[1] took note two intentional defaults by Germany, and notified the Powers oncerned. The Inter-Allied Conference opened at the Quai 'Orsay on Jan. 2 1923 when Bonar Law submitted the following cheme: a four years' moratorium; the Reparations Commission be replaced by a Foreign Council for German finance, a erman Minister presiding; the reduction of deliveries in kind; eduction of the German debt to 30 milliard gold marks; com- ensation for Inter-Allied European debts by allotting to Eng- nd the milliard of French gold and the Italian bonds held as a uarantee by Great Britain; the first series of German bonds to e allotted to France by priority. This somewhat complicated cheme deviated completely from those of France, Belgium and taly. If it abolished Inter-Allied debts it did away with any erious expectation of payments except to Great Britain.

On Jan. 3 after a ministerial council and consultation with heunis and Della Torretta, Poincaré declared Bonar Law's cheme to be quite unacceptable. The conference closed down n the 4th, in view of the impossibility of agreement. While efusing to subscribe to the French propositions, the British elegates declared that the friendly sentiments of the British ovt. and people remained unchanged. On the 9th the Repara- ions Commission, having heard the German delegates, made a tatement (Great Britian dissenting) that Germany had "de- iberately failed" to deliver coke and coal. Poincaré then in- ormed the German Govt. (Jan. 10) of the sanctions which he as going to apply, viz.: control of industrial production in the uhr by French engineers under the protection of an adequate ilitary force. President Ebert protested, and the industrial orkers in the Ruhr refused to carry out the deliveries of coal by rder of their Government. The Franco-Belgian occupation as accordingly established from Essen to Bochum and Dort- und. On the German side passive resistance was organised.

Such were the facts, the consequences of which were to be felt hroughout the year. In proportion as passive resistance became ore stubborn French control became firmer and more extended. ith Poincaré, everything else was subordinated to the success f the undertaking. Disturbing incidents followed in quick uccession. On Jan. 18 for instance, the Chamber passed a reso- ution by 371 votes against 143 for the suspension of parlia- entary immunity for Marcel Cachin who had been charged efore the High Court with conspiring against the security of the tate. But the Senate declined on May 24, and the Cabinet endered its resignation to the President of the Republic, who efused to accept it. On this occasion (June 14) Poincaré fur- ished explanations on his internal policy long awaited by the *loc national*, who supported him consistently without having ny share in the administration. "Leave the extreme parties solated," he said; "republicans who wish to belong to the ajority should not risk their alliances and their friendships mong them." His majority was only 376 against 207, neither adical-Socialists nor Socialists being included in it. Poincaré did not change his methods, however, but relied on the Right for his foreign and on the Left for his home policy. He kept the Chamber busy by devoting over 20 sittings to academical debates on teaching reforms, particularly on the reintroduction of compulsory Latin.

Meanwhile the Lausanne negotiations were concluded. To the great regret of many of their compatriots the French plenipotentiaries missed the opportunity of joining hands with Lord Curzon on the Eastern question. They showed considerable complaisance to the Turks, and sacrificed the interests of Christian populations and of institutions under the traditional protection of France. A portion of the Paris Press expressed disapproval of the treaty, which was finally signed on July 24.

In Aug. a change took place in Germany. In face of the slow but sure effect of the measures taken in the Rhineland, the Cuno Cabinet had to resign and was replaced by a Stresemann Govt. more inclined to submission. On Sept. 24 passive resistance came to an end, announced by President Ebert in a proclamation which called the people to submit, while indulging in violent recriminations against France. At this point Poincaré, under the influence of the more extreme Nationalists, took the serious step of acquiescing in, if not encouraging, a separatist movement in the Rhineland, whereas he had, up till then, proclaimed himself in favour of pure autonomy. German opinion was once more exasperated. Mr. Baldwin, who had been assured of Poincaré's moderate views when visiting Paris on his way from Aix-les-Bains, was taken by surprise, and foreign opinion in general, at first favourably impressed by French success in the Ruhr move, now turned against France. The franc fell, and the cost of living rose. Poincaré then withdrew his support from a movement palpably artificial; but the harm was done. The opportunity of exploiting the Ruhr victory had been lost. The anger of the separatists, the disappointment of the public and the accusations of the extreme Left disturbed opinion. Poincaré now accepted the idea of having a new scale of payments drawn up by outside experts in accordance with Germany's real capacity. On Nov. 30 the Reparations Commission decided to send two committees of experts to seek means of balancing the budget, to decide upon the measures to be taken for stabilising German currency and to "seek means of evaluating and bringing back exported capital." The execution of the Treaty of Versailles had taken a new turning.

THE FINANCIAL AND INTERNAL CRISIS

In vain did Poincaré defend his policy in impassioned speeches on all occasions—and particularly on Sundays; public confidence was shaken, loans became impossible, the exploitation of the franc by speculators had to be countered by a mass manoeuvre in dollars, cost of living increased and the claims of wage-earners and officials grew in proportion. On Jan. 6 1924 one-third of the Senate was replaced, but without any serious change in the composition of that Assembly. On the other hand, the elections in the Chamber, fixed for May 11, became the focus of a fierce struggle. The government scheme for straightening out the financial situation so as to avert the fall of the franc met with decisive opposition from the Left. The augmentation of taxes, particularly the *double décime* was passed with difficulty. The proposal to authorise the Government to proceed by decree with administrative reforms estimated to save a milliard was only adopted by 333 votes against 205 in the Chamber (Feb. 7) and came near being thrown out by the Senate which had approved the general financial scheme by only 151 votes (March 18). The parliamentary horizon was overcast. On March 26 the Cabinet was put in a minority in the Chamber (271 against 264) on the question of pensions, and resigned. Poincaré was charged to re-form the Ministry, which he did by giving François-Marsal Finance, de Selves the Interior, Loucheur Commerce and Henri de Jouvenal Public Instruction. Thus many radical Ministers were replaced by Moderates. The electoral law of 1919 was slightly modified to do away with certain inconsistencies and to reduce the number of deputies to 584. On Jan. 25 Poincaré had signed a Franco-Czechoslovakian alliance with Dr. Beneš.

---

[1] The British member dissenting (Ed. *E.B.*).

The election campaign was a heated one. Millerand's sensational speech at Evreux on Oct. 14 had really been the starting-point. The President of the Republic insisted on the necessity of confining legislative power to its proper function and of strengthening the prerogative of the head of the state. During April Poincaré made several important speeches in which he drew nearer to the *Bloc national*. The Radicals, Radical-Socialists and Socialists formed a Cartel, taking as their motto opposition to financial retrenchment and anti-Poincaréism. In several divisoins the Cartel included the Communists. When May 11 came, more than 9,000,000 voted out of 11,000,000 electors—a proportion never before attained. The results gave 277 seats to the Cartel, 267 to the *Bloc National*, 29 to the Communists and 11 to the candidates who belonged to no group. Of the Cartelist deputies 139 were Radicals and Radical-Socialists, 36 Republican-Socialists and 102 Unified Socialists. Taking the number of votes over the whole country, about half had gone to the *Bloc national*; the Republican Entente group alone accounted for 3,200,000 voters while the whole Cartel had only 3,400,000 to its credit.

Doumergue's Election.—Poincaré handed in his resignation at once, but carried on with current affairs until the opening of the new Chamber. On June 2 the Socialist Congress came to the unanimous decision not to take part in the new government, though supporting the Radical Socialists. Painlevé was elected President by the Chamber on June 4 by 296 votes against Maginot's 209. On the 5th Millerand offered to put Herriot in power, but Herriot refused to form a Cabinet so long as Millerand remained President of the Republic. He and his partisans could not forgive Millerand for having opposed them under the last Legislature. After turning in vain to friends such as Steeg, Millerand had at last to give in. He formed an interim Cabinet on June 8, under François-Marsal, for the purpose of laying before Parliament a memorandum in which he set forth his claim, to the effect that he had always respected the constitution and was still abiding by it in refusing to surrender his office without a definite vote from both Houses. The Senate refused to take action. The Chamber flatly refused to enter into relations with a government "which by reason of its composition, is the negation of parliamentary rights." On June 11 Millerand therefore resigned. The Cartel candidate for the Presidency was Painlevé, but at a preliminary meeting of the Congress 149 votes were given to Doumergue, president of the Senate, and it was he who was elected on June 13, by 515 votes against 309 for Painlevé.

Herriot's Ministry.—Herriot now proceeded to form the new Ministry, which was complete by June 14. Taking Foreign Affairs himself, he entrusted René Renoult with Justice, Clémentel with Finance and filled the remaining departments with other Radicals. The ministerial declaration marked a return to anticlericalism by announcing the suppression of the embassy to the Vatican and the intention of bringing Alsace and Lorraine within the scheme of French legislation as soon as possible, including secular education. The Chamber approved it by 313 votes against 234 (June 19); but on the same day the Senate elected de Selves as president, in place of Doumergue, by 151 votes against 134 for Bienvenu-Martin, the Cartel candidate. The two Assemblies, both Radical, were not of the same school.

The new majority made a point of reversing the work of their predecessors in every point and expressed the intention to secure for their own party "all the appointments, and that at once," as their principal organ the *Quotidien* phrased it. Some measures have therefore a symbolic importance. Gen. Sarrail was recalled for service without age-limit; the review of July 14 at Longchamps was cancelled; university reforms were dismissed with a stroke of the pen; the monopoly on matches was reinstituted; the economic and military evacuation of the Ruhr was brought under consideration; the Moscow Govt. was recognised *de jure* (Oct. 28) without any condition or guarantee for the Russian debt; an amnesty was proposed to be applicable to fiscal offences, events connected with strikes, desertion, cases of intelligence with the enemy and cases of *forfaiture*—the last two named categories including the cases of Caillaux, Malvy and the *Bonnet Rouge*! Not until the end of the year (Dec. 16) did the Senate pass this Act of Amnesty, voted by the Chamber as early as July. The anti-clerical policy of the Government produced considerable agitation. A letter was sent to the president of the council from the French cardinals denouncing the lay laws as "persecuting laws," and a "National Catholic Federation," presided over by Gen. Castelnau, was formed, which had a large following in the west and also in Alsace and Lorraine, where church schools are traditional, whereas French law recognises only lay and neutral schools. A National Republican League on parallel lines was formed by Millerand on Nov. 7 to combat "demagogy, revolution and anarchy."

The Dawes Plan.—Herriot's attitude with regard to Reparations was the reverse of Poincaré's. Instead of merely changing methods of negotiation which were open to criticism, he abandoned without resistance the positions held by his predecessors. On a visit to Ramsay MacDonald at "Chequers," he associated together the three problems, reparations, inter-allied debts and security. As a result, MacDonald felt authorised to issue a programme for the Inter-Allied Conference which allowed for concessions, hitherto regarded as inadmissible, on the part of Germany's creditors. Feeling ran so high in France that Mr. MacDonald hurried over to Paris on July 8 in order to draw up a fresh programme. It was in fact a question of accepting and applying the Dawes Plan which had been put before the Reparations Commission on April 9.

At the London Conference of July 16–Aug. 16, at which German delegates were present from Aug. 5 onward, conditions—very favourable to Germany—were adopted; attenuation of the debt; limitation of the Reparations Commissions powers; a loan of 800,000,000 gold marks; suppression of coercive measures and of Franco-Belgian *régie* in the Rhineland; a promise to evacuate the Ruhr before Aug. 15 1925; while Mr. Ramsay MacDonald undertook to seek a solution of the Inter-Allied debt problem, bearing in mind all these points. On his return to Paris Herriot was vigorously criticised in Parliament. In the Chamber, after six sittings devoted to debate, he obtained a vote of confidence by 336 votes against 204 (Aug. 23). In the Senate on the 26th, he secured 181 votes. His task was not made easier by Ramsay MacDonald's rejection of the Treaty of Mutua Assistance which had been elaborated in agreement with Lord Cecil by a commission appointed by the League of Nations. At the fifth meeting of the League Herriot succeeded, however, in regaining a portion of his prestige, by proposing the principles of "arbitration, security, disarmament," which became the basis of the Geneva Protocol. A few weeks later, on Oct. 30, he was able to settle by arbitration the dispute over the free zones of Savoy with Switzerland (*see* SWITZERLAND).

On the reopening of the Parliament the Radicals and Socialists continued their policy of supporting the Government, with the approval of their party Congresses. The Communists adopted a hostile attitude to the Socialists. On Nov. 23, when the ashes of Jaurès were transferred to the Panthéon, they gave the ceremony the appearance of a *revue* of Communist forces in the streets of Paris, entailing an accusation of weakness against the Government. Great difficulty attached also to the preparation and discussion of the budget in view of the promises made during the election period and the demands of the Socialists. Clémentel, who represented the moderate element in the Cartel, had retained the taxes voted by his predecessors; but no sooner was the equilibrium within sight of accomplishment than it was upset by a new revision of the scale of officials' salaries. From the expected figure of 32,800 millions the budget rose to 36 milliards and the pound sterling, which stood at 70 francs during the elections, was now at 91. The programme of the Socialist Conference at Grenoble in Feb. 1925, the Communist strike (accompanied by bloodshed) at Douarnenez, the fracas on Feb. 8 at Marseilles, which resulted in the death of three and wounding of 20 people at the close of a Catholic meeting—combined to bring discredit to the Government. No less grave and significant was the Quartier Latin affair in March. An immense majority of the students protested against the nomination of an ill-qualified ndidate as lecturer in the faculty of law in Paris. The dean the faculty was suspended by the Ministry for having refused allow the police to enter the premises. The whole Press rang th the consequent disturbances.

The suppression of the embassy to the Vatican and the threat lay-teaching in Alsace and Lorraine threw those two provinces to a state of growing unrest. On April 2 Clémentel resigned account of his bad reception by the Senate. He was replaced Monzie, who demanded of Herriot the retention of the em- ssy to the Vatican; but this patching up could not save the abinet, and on April 10 the Senate, exasperated by an infla- on of four milliards concealed in the balance-sheet of the anque de France in despite of solemn promises, threw the Gov- nment out. In February, following on a German note suggest- g a pact of security in the West, confidential negotiations were ened between the Cabinets concerned. These were continued semi-secrecy until autumn.

The Painlevé Ministry.—This particular crisis was difficult to olve, as the Socialists refused to accept portfolios, but Pain- vé finally succeeded on April 17 1925. He took War and the residency of the council, giving Foreign Affairs to Briand and inance to Caillaux. This last appointment caused a great nsation, but as the public had, after all, faith in Caillaux's chnical ability and desired principally to see the financial roblem settled, his war antecedents were overlooked. The inisterial declaration was manifestly designed to relieve the trained situation. It proclaimed the retention of the embassy t the Vatican in a new form, and reassured Alsace-Lorraine gainst any too precipitate assimilation. The Government had a ajority of 304 against 217 votes. The agitation in the Latin Quarter was allayed by the reinstallation of the dean in the aculty of law. Unfortunately, the Communist agitation ended n the shooting of four partisans of the Youthful Patriots *jeunesses patriotes*) in the rue Damrémont at the close of a meeting. The Prime Minister and the Minister of the Interior attended heir funeral at Notre-Dame. To prevent the recurrence of like ncidents, May Day processions in the open street were forbidden nd May 1 therefore passed in perfect calm. The Government ikewise forbade all street processions on May 10, the fête of oan of Arc, but the usual delegations made their pilgrimage to he statues of the saint, and the Prime Minister deposited a wreath in person. Herriot had been re-elected president of he Chamber by 266 votes only. On April 5 Millerand was lected Senator of the Seine by 520 out of 1,025 votes. The municipal elections (May 3 and 10) showed a slight progress owards the Left as compared with those of 1918, and at the ame time a striking set-back for the Communists.

Abroad the outlook was still uncertain. The Conference of Ambassadors had decided, in conformity with the Versailles Treaty, that the Cologne zone should be evacuated only after Germany had completed her disarmament. An Inter-Allied financial conference, that was held in Paris on Jan. 14, had settled the distribution of payments to be made under the Dawes scheme and that of the profits accruing from the occupation of the Ruhr. The election of Hindenburg to the presidency of the Reich (April 26) on the sudden death of Ebert had aroused great uneasiness among the Allies. In May a considerable financial and military effort was entailed by 'Abdel-Krim's attack on the Moroccan front. Painlevé flew over to Morocco by aeroplane to review the situation. He then sent Malvy to Madrid to arrange a plan for collaborating with Spain, and Marshal Pétain to Morocco to direct the military operations. In October, after the Riffs had been thrown back on their old front, Marshal Lyautey was replaced as Résident-Général by Steeg. Monzie became Minister of Justice and Yvon Delbos took the Ministry of Public Instruction. This first reconstitution of the Ministry had no political significance, but this could not be said for the next.

Dislocation of the Cartel.—July 12 saw a rift in the Cartel. For the first time, on the subject of the budget and the sales tax, the Socialists, Radical-Socialists and a certain number of Radicals voted against the Ministry, which was saved by the votes of the Opposition who were anxious above all to find a way out of the financial predicament. The *Conseils généraux* elections (July 19 and 26) showed a slight leaning to the Left and the intransigeance of the Socialists became more marked. On Aug. 15 the Socialist Congress in Paris began by excluding Deputy Varenne from the party because of his acceptance of the post of Governor-General of Indo-China. A motion was then passed (by 2,210 against 559) against Blum's proposal to censure any support of Painlevé's Cabinet but permitted the support of a Ministry "determined to bring about the reforms demanded by the proletariat." Inclusion in the Ministry remained forbidden in any case. The ever-increasing financial difficulties intensified the dissension. Caillaux failed to justify the hopes reposed in him. Instead of holding fast to a general financial scheme he became involved in party politics. To clear up the situation by the settlement of Inter-Allied debts he left for the United States in September, but only to return in October empty-handed. The consolidated 4% gold loan, which he had launched during the summer and by which he hoped to realise some 20 milliards produced barely six. Confidence was gone. At the end of Oct. misunderstandings in the majority ranks found expression at the Radical Congress at Nice, the speeches of Herriot and Caillaux revealed a fundamental difference, and Painlevé's long speech rather served to add to the confusion. Finally the Congress, unable to decide between the levy on capital and the more practicable taxes, adopted a vague formula recommending a "special contribution payable on all kinds of income and capital."

The Second Painlevé Ministry.—The brief credit enjoyed by the Government on the conclusion of the agreements signed on Oct. 16 at Locarno—for which Briand had paved the way during the 6th meeting of the League of Nations by agreement with Chamberlain, Benes and Skrzynski—did not help them for long. For one thing, French opinion was by no means unanimous in its approval of the agreements which were designed to replace both the Geneva Protocol (never ratified), the Security Pact of June 28 1919 and certain guarantees of the Versailles Treaty. On returning from Nice, Caillaux was unable to secure his colleagues' approval of his financial projects. To get rid of him Painlevé handed in the resignation of the Cabinet collectively on the 28th, and formed a new Ministry in which he took Finance himself. But in the Chamber he obtained a majority of only 221 votes against 189, owing to the abstention of the Socialists. The Socialist National Council, for its part, voted against him by 1,431 against 1,228. At the same time Gen. Sarrail's anticlerical sectarianism, Turkish sympathies, presumption and blunders in Syria brought about sanguinary encounters in the Jebel Druz and later in Damascus, which amounted to local disasters. Painlevé was at last obliged to recall him. When he put his financial schemes—badly conceived and co-ordinated—before the Chamber, he was already discredited. On Nov. 22 he was thrown out by 277 votes against 249. The Treasury was so hard pressed that he had to pass an emergency vote for an advance of 1,500 million francs from the Banque de France.

Another Briand Ministry.—Entrusted with the construction of a new Cabinet, Briand failed at first through the non-collaboration of the Socialists. Doumer, and after him Herriot, met with no greater success. Then, as the Socialists were meditating a *coup de force*, Briand yielded to the pressure of the President of the Republic and tried once more. He succeeded on Nov. 28, taking Foreign Affairs himself, sending Painlevé back to the War Office and, in spite of his objections, gave Finance to Loucheur who imagined he could straighten out the situation. The Ministry was still Cartellist, although Georges Leygues (Navy) and François Jourdain (Pensions) represented the Moderate elements. A change of policy was now perceptible, the developments of which appeared in December. Loucheur's scheme, once published, proved so great a disappointment that the Finance Minister had to resign. After groping a while pursued by the clamour of the extreme Left, Briand replaced Loucheur by Doumer. Several Cartellist ministers talked of resigning, but Briand unmoved stood by Doumer and gained the approval of the entire Cabinet for his schemes. The pound sterling oscillated at about 130 and the dollar at about 26 to 27 francs.

As soon as his Ministry was formed Briand went to London to sign the Locarno agreements (Dec. 1). By the end of the year foreign affairs looked more promising. The Dawes scheme functioned accurately, and the Cologne area was evacuated without incidents. In Morocco the vanquished ʽAbdel-Krim saw himself abandoned by the tribes; in Syria Henry de Jouvenel, appointed high commissioner, began to restore order and confidence; in central Europe, Poland and the Little Entente (*q.v.*) were following a policy parallel to that of France. Relations with England were cordial. The one great remaining problem remained the settlement of Inter-Allied debts, the shadow of which darkened a financial horizon already heavy with clouds. (A. Gn.)

The Locarno treaties were ratified by the French Chamber on Nov. 2 1925. The chief preoccupation of ministers in the new year was the financial crisis, the solution of which was rendered more difficult by the lack of an absolute majority in the Chamber. The Govt. made the tax on payments, M. Doumer's most important proposal, a matter of confidence. They were defeated by 274 votes to 221. Their resignation (March 6) took place two days before the opening of the special session of the Assembly called to arrange for the admission of Germany to the League.

The fall of M. Briand was a calamity at this moment, and, after a fruitless invitation to M. Herriot to form a cabinet, M. Briand assembled a ministry, with M. Raoul Peret at the Finance Ministry. A Finance Bill, providing for new or increased taxation, was passed (April 29), but the franc still fell. At the end of April it stood at 147 to the pound. Money was required for Morocco, where the new offensive was begun early in May. On May 19, on M. Peret's return from London without having settled the debt, the franc fell to 171. In June M. Peret resigned, and then the whole Government. After a delay of a week, during which M. Herriot had failed to form a ministry, M Briand, again took office, with M. Caillaux at the Ministry of Finance, and the latter was faced at once with the problem of protecting the franc. (Ed. *E.B.*)

II. ECONOMIC AND SOCIAL HISTORY

In the course of the negotiations for the payment of France's debts to her Allies it has been persistently said, in particular by Americans, that France is the richest country in Europe, or at least in continental Europe. This opinion, very flattering to the French, is in some respects well founded; for since the fall or the amputation of the great empires of central Europe, France is, after Russia, the most extensive European country. Her soil is fertile. She owns the richest iron deposits in Europe, and, if her coal does not suffice for home consumption, she has by way of compensation more water power than any other European country except Norway. In addition she has a colonial empire, the second in the world and 20 times the size of the mother country. It is true that her population places her fifth in order of countries, but it is by her own choice that its increase is limited.

But the formidable damages inflicted by the War are not taken sufficiently into account. The world still remembers France's rapid recovery after the war of 1870–1, and supposes that this is a similar case. But the two situations are not in any real sense comparable.

If the national wealth of France were evaluated in gold currency or, to be exact, in the currency of 1914 (which is not the same thing, for we know that gold has lost a great deal of its value), we should arrive at a figure far below that of 1914. It is difficult to make a definite statement, but, speaking generally, the accepted pre-War figure was 300 milliard gold fr. whereas the present figure would not, we believe, reach 200 milliards, in spite of the restoration of Alsace-Lorraine.[1]

But leaving aside these general considerations let us examine, in two successive sections: (1) agriculture, mines, industry and commerce, with a comparison under each heading of the present situation with that of 1911–3; (2) the changes that have taken place in respect of workers' legislation, the social movement and population.

Production

Agriculture.—French agriculture suffered cruelly in the War; (*a*) in consequence of the occupation and of the destruction of part of its area; for certain portions of the ground—the part since known as the Red Zone (about 30,000 hectares)—were laid waste by shell to such an extent that they could no longer be cultivated in any way; (*b*) in consequence of scarcity of labour, live stock and manure, which had the effect of bringing cultivation to a standstill or of greatly impoverishing the crops for a long time after the War; (*c*) by the destruction of forests (several hundred thousand hectares) which must take 20 to 50 years or even longer, to grow again.

The area under cultivation is smaller to-day, whether we take the absolute or the relative figures, than it was before the War. From 1904 to 1913 its extent was 23,000,000 hectares (cereals, fodder, leguminous crops, vines, etc.), which represented in relation to France's total area of 52,952,000 hectares 47%. In 1923 it was only 20,432,000 hectares, although the area of France, aggrandised by Alsace-Lorraine, amounts to 54,400,000 hectares. The proportion is therefore now only 37·5%. This reduction of the cultivated areas is explained by the diminution and the high cost of agricultural labour, as the result of which landowners find it more profitable to convert their land into pasture.

It may be argued that the decrease in the areas matters little if there is a compensating increase in yield. Unfortunately this is not the case. There is certainly a general improvement in the yield per hectare, but not enough to compensate for the decrease in area. The result is that production is decreasing in the case of almost all agricultural products. The following are the figures for certain products, taken from a paper by M. Augé Laribé in the *Revue d'Economie politique*, March–April 1925.

		1904–13	1923–4
Cereals	Million quintals	88	76
Potatoes	Million quintals	133	127
Beetroot	Million quintals	58	44
Milk	Million litres	128	117
Wool	Million kilogrammes	34	20

It is only in the case of vines and fodder that production shows a small increase.

The live stock of the country, greatly reduced by the War, is still below pre-War numbers. It is evident from the following figures (*Annuaire statistique de la France*) that the deficit is still very considerable.

	1913	1924	Decrease
			%
Horses, mules, donkeys	3,222,000	2,859,000	11
Oxen and cows	14,788,000	14,025,000	5
Sheep and goats	16,131,000	10,172,000	37
Pigs	7,036,000	5,802,000	18

Nevertheless, in some directions, progress has been made. Manure is being more largely used, thanks to the work of the agricultural syndicates, but France is still far behind other countries in this respect, although she possesses very abundant supplies of phosphates in Northern Africa and, since the restoration of Alsace, a rich deposit of potash also. The employment of electric power, whether derived m waterfalls or from coal, is beginning to spread in country dis-ts owing to the formation of co-operative societies of consumers power. The state has voted a credit of 600,000,000 fr. for this pose. The shortage of labour is being compensated by the im-gration of foreign workers who are mainly Italian and Spanish in south, Polish and Belgian in the north. The southern region ich lies along the Garonne had become a deserted country in con-uence of the decrease in the local population, but is now being tored by the Italians, who come not merely as labourers, farmers métayers, but also to buy land and settle on it. It is undoubtedly anomaly, this colonisation of so ancient a country as France, and results may be dangerous from a national point of view. But n if it be an evil, it is at the same time a remedy for that greater l which has proved fatal to other countries, viz.: desertion of the d for lack of men to work it. The depreciation of the currency has n a blessing in so far as it has enabled most small holders to pay their mortgages and many farmers to buy their farms outright.

---

[1] Mr. Harvey E. Fisk of the Bankers Trust Co., New York, concludes his exhaustive analysis of French public finance (1922) in these terms: "We believe that, notwithstanding the losses occasioned by the War, the wealth of France today, estimated on a specie basis, closely approximates or perhaps equals her pre-War wealth. This is partly due to the repatriation of Alsace and Lorraine, but it is also due to the fact that the War apparently served to intensify the normal saving habits of the people, and thus enabled them to meet the burden which it brought without seriously impairing the pre-War national fortune." (Ed. *E. B.*)

Mines and Water-power.—The invaded regions were the very es richest in mines. They produced half of France's total out-t of coal and three-quarters of that of iron. The coal-mines re systematically destroyed by the Germans; during the War 2 shafts and 1,910 kilometres of galleries were demolished or rnt out, and have had to be not merely repaired, but entirely onstructed. In 1925, by dint of immense efforts, production d been brought back to the pre-War figure, but the output 12 whole years had been lost.

It is true that, through the recovery of the Lorraine mines, ance—already a large producer of iron ores—has come into e front rank among European nations in that capacity. Her oduction of coal, however, was always much below her con-mption, and the restoration of Alsace-Lorraine has not altered is state of things.

The figures of coal production and consumption are as follows:—

Year	Production	Consumption
	tons	tons
911	39,280,000	59,500,000
913	40,844,000	64,800,000
924	44,955,000	76,900,000

At first sight there would seem to have been a considerable crease both in production and consumption, but this is an illu-n. As regards production, of the 45,000,000 tons produced in 24, more than 5,000,000 are from the restored Lorraine region; ducting this amount, it will be seen that from the rest of France e output is slightly below the pre-War figure, so that there s been no progress at all in the 12 years. Similarly, as regards al consumption, Alsace alone consumes 11,000,000 tons, so at in 1924 the consumption of France without that province s only 66,000,000, or about the same as in 1913. The deficit s in fact been augmented, for while in 1911 it amounted to ,000,000 tons only, in 1924 it had risen to 32,000,000 tons. is made up by the import of coal, which comes mainly from e Saar, Germany and England. If the Saar basin were to be-me permanently French, it would go far in redressing the in-fficiency of coal; but this question is to be settled by a plebi-ite in 1935, and it is probable that the decision will be in favour Germany. In that case, however, Germany would have to y France the value of the Saar mines, which has been fixed at 0,000,000 gold marks.

There is, however, a real and considerable increase in the pro-ction of iron and its derivatives; production is in fact nearly ubled, as may be seen from the following figures:—

Year	Iron Ore	Pig Iron	Steel
	tons	tons	tons
1911	16,600,000	4,470,000	3,837,000
1913	22,000,000	5,207,000	4,687,000
1924	29,000,000	7,693,000	6,900,000

Consumption, however, lags far behind production; even be-re the recovery of Lorraine, France was unable to absorb all r production, and is less able to do so now. The reason is that e produces very little coke, and coke is indispensable in the oduction of pig-iron. She has, therefore, no alternative but export her surplus of ore and of manufactured iron, and even is is a matter of difficulty as, since the War, the metallurgic industry has been in a state of depression marked by underselling and falling prices. In the matter of her metallurgical wealth, therefore, France has less cause for satisfaction than is generally supposed.

As to petroleum, France had formerly none at all, but with Alsace she has now acquired a few small wells. An oil-field has just been found in the Mediterranean region (department of Hérault) but it is not yet known what the yield will be.

The insufficiency of coal-mines is to some extent counterbalanced by the abundance of waterfalls which can be used for motor power. With the Pyrenees, the Alps, and the mountains of the centre, France is at least as well equipped as Switzerland and Norway. Before the War the amount of power utilised was valued at no more than 480,000 kilowatts (640,000 H.P.). In 1924 the figure was over 1,000,000 kilowatts. Plans for the utilisation of 4,000,000 additional kilowatts are in progress, and the total utilisable energy is calculated at 8,000,000 or 10,000,000. The increase, however, though extremely rapid after the War, is now tending to diminish owing to the great rise in the cost of installation, so that coal-power once more becomes the cheaper of the two. Nevertheless, France has already found in water-power a source of considerable wealth, for in addition to the amount employed for lighting and for running railways and tramways, a large number of industries, both metallurgical and chemical, have arisen as a consequence of this new motor power.

Industry.—French industry was hit even more directly than agriculture by the War. Those regions which were invaded, and in great part devastated, represented, it is true, only 5% of the total area of France, but they accounted for more than 10% of the population, 14% of the total number of industrial workers, 29% of the textile and 53% of the metallurgical production. They were in short the focus of the nation's industrial activity. Reparation of the damage done has cost the state 84 milliard fr., and 20 milliards have still to be paid. From the financial standpoint the losses are irreparable. We are not, however, concerned here with the financial situation, but with the question of whether, from the industrial point of view, a complete recovery has been made. The answer is yes, and no.

In certain respects undoubtedly, French industry gained through the terrible experience of war. Factories reconstructed in the devastated areas made good use of the enormous indemnities that they received from the state. They are reported to have had the use of extravagant sums, but they justify their case by saying that the money was spent on installing the latest improvements and that those installations would probably not have been made but for the War. In like manner factories have learnt to renew their stock of tools and to adapt themselves to new requirements by manufacturing at home articles for which France had formerly sent abroad, particularly to Germany; these included, for instance, chemical products, dyes, magnetos for motors, Diesel engines, electrical apparatus for wireless telegraphy, optical and photographic lenses and all the industrial requirements of aviation. The motor industry has made immense strides; the pre-War figure of about 100,000 cars in use has been increased to over 450,000 in 1925. Even the oldest industries received a new impetus through the War. In the bakery trade, for instance, only half of the establishments used a mechanical kneader; and after the War it was used by 88%. It must be said that the general adoption of the eight-hour day hastened the introduction of mechanical contrivances but this itself was a result of the War.

But while admitting these points, it is none the less true that French industry, taken as a whole, has not yet recovered from the shock of war. Certainly, the losses among industrial workers —(267,000 killed and about 130,000 disabled)—were less heavy than among agricultural labourers, because the greater number of skilled workmen were withdrawn from the front to work in munition factories. The deficit was more than covered, too, by the immigration of foreign workers. Every year, since 1922 especially, there is a contingent of 200,000 to 300,000 of whom two-thirds are industrial and one-third agricultural workers. In the mines to-day, something like one-third of the personnel is made up of foreigners.

But if there is no diminution in numbers, there is nevertheless diminution of output. Not only does the foreigner, who is often inexperienced in his particular branch of employment, produce less than the Frenchman of earlier days, but the Frenchman himself produces less than before the War. It is difficult to say whether this is the result of a limited working day or of discontent connected with Socialistic ideas; in either case, the facts are incontrovertible. To take one example only, the quantity of coal produced per head in 1913 was about 660 kilogrammes; in 1925 it is 510 kilogrammes. The diminution is rather less if the calculation is based upon the underground workers who extract the coal, but even in their case the quantity extracted shows a diminution of 5%, the present figure being 568 kilogrammes as against the earlier 595.

Then again, although the technical advance in industry has just been demonstrated, the total of horse-power used in industry, excluding transport, has not risen to any great extent (1911, 3,141,000 H.P.; 1913, 3,539,000 H.P.; 1922, 4,800,000 H.P.).

But Alsace-Lorraine accounts for a large share in the last of these figures and, if we deduct that share, the augmentation for pre-War France remains inconsiderable. It is a different matter with water-power, but that we have already discussed.

Taking the principal industries, we shall see that production has diminished, notwithstanding assertions to the contrary. The following are the figures for silk, which is pre-eminently a French industry:—

	Weight of Cocoons	Weight of Silk Yarns	Value of Silk Piece Goods
	kilos	kilos	francs
1911	5,109,000	411,000,000	414,000,000
1922	2,585,000	209,000,000	2,229,000,000
1923	4,180,000		2,812,000,000

It is evident that production has greatly diminished, the quantity produced being almost halved. The third column figures, taken alone, show on the contrary a septuple augmentation; but on what does it rest? Merely on the fact that the price of raw silk has been multiplied by 8, mounting from 35 fr. a kilo in 1911 to 278 fr. in 1923. We have therefore only to divide this nominal figure of 2,812,000,000 by 8 and we have left 350,000,000 gold fr., that is, a figure smaller than that of 1911.

In the case of sugar refineries the diminution amounts to one-third, as these figures show:—

1911–3	average 671,000,000 kilogrammes
1922–4	average 446,000,000 kilogrammes

Lastly, there is the building industry, that industry which supports so many others—as the French proverb has it: "When building goes well, all goes well." In the War years, it was practically non-existent; in 1924 and 1925 it was coming to life again, but only slowly. In Paris in 1911 there were 1,792 applications for permits to build houses, in 1919 only 173—not even one-tenth! But in 1925 building was resumed on a considerable scale in the capital.

Commerce.—Internal commerce has suffered but little, even during the War; it recovered immediately after the War, gaining a fresh impetus from the rise in prices caused by the depreciation of the franc, and profiting also by the influx of foreigners attracted precisely by that depreciation, which set a premium on their dollars, pounds or florins as the case might be. We have an indication of the fluctuation of the internal commerce in the special tax on sales. This tax brings in round figures 4 milliards of paper francs. As it is established at a fixed rate of 1·30%, it assumes an annual sales figure of 300 milliards—one might safely say, 400 to 500 milliards, *i.e.*, about 120 milliards of gold fr. on the basis of the exchange in 1924, for the declarations are assuredly much below the real figures. But unfortunately this tax did not exist before the War and we have therefore no basis of comparison.

Progress on the railways is, however, easier to assess; there is considerable increase in passenger traffic (35%) but less in goods (13%):—

	Goods	Passengers
1911	184,000,000 tons	511,000,000
1923	208,000,000 tons	689,000,000

In spite of a large increase in gross receipts the railway companies are losing money at the rate of 1,000,000,000 fr. a year. This is because the French charges, though they have been frequently raised, are still (on a gold basis) lower than they are in other countries.

The total length of the railway system has not been increased since the War (40,615 km. in 1911; 41,853 km. in 1923; but of these 1,250 were for Alsace), because the cost of construction is so heavy that even the old tracks have to go unrepaired. The system is, however, practically large enough to meet requirements.

In the mercantile marine, there has been a considerable increase: 1911, 1,413,000 tonnage net; 1913, 1,582,000 tonnage net; 1923, 2,145,000 tonnage net.

Sailing vessels account for only 386,000 of the total tonnage of 2,145,000. The increase since 1913 is therefore more than a third (35·6%). France lost nearly half of her merchant fleet during the War (700,000 net tonnage), but Germany was made to hand over to her an equivalent fleet. Besides, the enormous rise in freight after the War (now a thing of the past) was a great incentive t construction.

As regards international commerce, it is generally held tha the position of France is excellent, better indeed than before the War. This is true, but only in part; the figures need more careful inspection. The following are the statistics of values and quantities:—

	Imports		Exports	
	Value in Millions of Francs	Weight in Millions of Quintals	Value in Millions of Francs	Weight in Millions of Quintals
1912	8,231	397	6,712	203
1913	8,421	442	6,880	221
1924	40,132	565	41,454	294
1925	43,980	474	45,413	302

It will be seen that a comparison of the mean of the years 1912 and 1913 with that of the years 1924 and 1925 shows an enormous increase in values, the imports being more than five times, the exports more than six times larger. At the mean rate of exchange in 1924 and 1925 the import figures would be 12 and 11 milliards of gold fr respectively; the export figures 12·2 and 11·2 milliards respectively. The increase in quantities has been less: 24% on the imports, 40% on exports. It is not to be denied, moreover, that this increase is due to the depreciation of the franc to which we just now attributed the influx of foreign visitors, for this is why, despite the rise of prices in France, actual prices (gold prices), costs of production, and wage are lower in France than in foreign countries.

But the greater increase in exports and the smaller increase in imports has in fact served to turn the trade balance in favour of France. For while in 1911 and 1913 the export figures remained lower by nearly 2 millards of fr. than the average import figures, in 1924 on the contrary they exceeded the import figures by more than 1,300,000,000 (300,000,000 gold francs).

It would seem, therefore, that this favourable balance ought to improve the exchange and bring about a rise in the franc, all the more as the unknown, but considerable figure (probably more than 1 milliard gold fr.) of what are called invisible exports—that is, purchases made by passing visitors—may be added. On the other hand it must be remembered that France has almost entirely lost her credits held abroad in the shape of shares debentures and state loans. Of this wealth, which amounted to 40 or 50 milliard gold fr., a large portion was diverted during the War. Another part, comprising Russian, Austrian and Turkish bonds, has practically melted away; and this magnificent holding of foreign credits cannot unfortunately be restored, or at least can only be restored by secret methods, because an unintelligent fiscal policy prohibits or at least handicaps heavily all kinds of investments abroad. The figures of French commerce include those of the trade done between the mother country and her colonies and these can have no effect on the exchange, the currency being the same on both sides.

It is not our intention to discuss the immense question of protection. We will only say that the War, far from having shaken Protectionism, has fortified it, not only because fiscal necessities call for the imposition of duties, but because fear of blockade leads each nation to think that she ought to be self-sufficing; and if, in those countries which appeared to be converted for good to free trade, such as England, Holland, Denmark and Switzerland, protection is gaining ground, with how much more justification will it become rooted in France? The only hope is that the breath of internationalism, which has created the League of Nations, may also bring into being economic unions between several countries. No serious progress has yet been made with those economic understandings between France and Germany which have many times been proposed on both sides of the Rhine.

SOCIAL ECONOMY

Labour Legislation.—During the War, social questions naturally lost their interest for the public. Even the application of laws for the protection of men and women workers was set aside in the interests of national defence. Workers mobilised in muni-n factories, worked day and night without protest, stimulated th by the incredibly enhanced rate of pay and by the fear of ing sent to the front.

Even when the War was over, the opinion of business men and onomists held that this intensive labour should continue, at ast until the day when the ravages of war should have been paired on the ground that the work of restoring the devas- ted areas was no less urgent than that of national defence. ut the workers were deaf to this appeal; indeed they clamoured r the adoption of the eight-hour day awaited for 20 years, d celebrated in anticipation on each May Day. Parliament red not resist this pressure; and the Act of April 19 1919 estab- hed in principle the eight-hour day, leaving, however, the plication of the law to be adapted to the special conditions individual industries by technical commissions. This was a fficult task, not yet satisfactorily solved. So far the eight-hour y is only applied to some 5,000,000 workers distributed among trades. The trades unions protest violently against these lays; but all business men and a fair number of economists rsistently oppose the Act, in which they see one of the principal ctors in the rise of prices. Its partisans argue that in the case a number of industries productivity has been maintained nd even augmented, notwithstanding the eight-hour day.

Several other laws, on the same lines as this general law, ve been promulgated to secure the weekly holiday for trades- ople by compulsory closing of the shops and to forbid night ork in the bakeries. These laws meet with violent opposition the part of small traders or small bakers who, as they employ paid labour, claim the right to work themselves when and w they please. There is also a law of June 10 1915 ensuring a inimum wage to women working at home. This is in imitation the similar law in England. The insurance benefits against cidents, which had only been granted to industrial workers, ere extended to agricultural labourers by a law of Nov. 15 22. Another law of 1916 concerns economic life; it prohibits illicit speculation," that is, the extravagant raising of prices. his law was, it is true, repealed in 1922, but there is an agita- on for its renewal. The question leads to passionate arguments, r it opposes the idea of equitable prices to the classic law of upply and demand. There are numerous laws by which loans state funds are granted to co-operative societies, concerned ith credits, consumption or production; also to societies of tisans employed in small industry and of agricultural workers r the acquisition of land, special advantage being given to dis- led ex-soldiers. We may also mention the creation of a Na- onal Economic Council composed of members elected by all e great national organisations. It has no legislative powers ut aims at enlightening the Government and preparing draft gislation.

In addition there are numerous important measures under onsideration, vigorously demanded by the *Confédération Géné- le du Travail* and by the Socialist party. The following are e principal demands:—

(*a*) The establishment of a *general social insurance*, covering all e risks in life: illness, old age, disablement, unemployment, aternity, etc. This project likewise arouses lively opposition, on count of the enormous charge entailed on industry and on the ational budget at a time when the financial situation is in itself itical. Neither is it favourably regarded by the Mutual Insurance ocieties, corresponding to English Friendly Societies, who depend the voluntary contributions of their members and see themselves danger of being eliminated by a compulsory insurance scheme. evertheless, it is certain that the bill will be passed, in a more or ss modified form, for the Radical Socialist party has declared its tention to side with the Socialist party in supporting it.

(*b*) The establishment of a *contrôle ouvrier* which would authorise e workers—or rather the trades unions—in every factory to inter- ne in all questions of labour organisation, such as the workshop gulations, engagement, dismissals, discipline and so on.

(*c*) The workers' right to claim a certain number of days as olidays: this would give legal sanction to a custom which is becom- g general to-day.

(*d*) The right to receive a minimum wage, increased by allowances roportionate to the number of children. Here again it is a case of gal sanction for a custom of family allowances which, though of cent introduction, is already in use in many establishments. But these allowances are at present paid actually by the employers, and the trades unions will not accept this, seeing in it a means of binding the worker on the pretext of assisting him. They claim family allowances, but on a compulsory basis.

The Social Movement.—As long as the War lasted we had, if not social peace, at least a truce from social strife as from political strife. The middle class and the working class had fraternised in the same trenches. But this truce did not last. The working classes returned from the War disappointed and irritated. They had been laden with laurels for saving their country, promised a new world, and when they had to go into harness again, life seemed harder and the wage system more intolerable than ever. The rise in prices, due to a factor of which for years the public remained ignorant, viz.: depreciation of the currency, increased that irritation. Undoubtedly a rise in wages followed the rise in prices; in the first years of the War it anticipated it indeed, but after the War, the advance in wages fell behind the advance in prices, and adjustment was frequently obtained only through fighting and strikes. The index number of wages which had (almost) caught up with the index number of prices, again lagged behind on account of the fall in the value of the franc at the end of 1925.

The two columns below show the index numbers of retail prices and those of wages at corresponding dates. The parallelism of the two ascending lines would be still clearer if shown in a graph. It should be remembered, however, that index numbers of wages are far more difficult to determine than those of prices. Instead of taking more or less arbitrary averages, we have chosen to take wages in a single industry, that for which the most definite statistics are obtainable, namely the coal-mining industry (taking underground and surface workers together) as indicative of the wage movement in general.

	1914	1920	1921	1924	1925
Retail Prices . .	100	390	352	401	435
Wages . .	100	360	349	423	437

The same parallel movement is found in the salaries of minor employees and officials, but not at all in the case of higher officials whose salaries have often not even been doubled.

It must be admitted that when the worker does obtain wages proportionate to the rise in prices, he is not satisfied, for he does not see why, with his wages quadrupled, he cannot satisfy his requirements better than before the War. He feels that he is being duped and it irritates him. Then, too, the worker's requirements—particularly those of the agricultural worker—are much greater since the War. This is due to the lavish distribution of meat, coffee, tobacco and alcohol to the soldiers, the taste for which has survived and the desire for which is stimulated by the spectacle of the scandalous fortunes that are acquired through the rise in prices and through speculation.

The people's saving-banks have had their deposits greatly augmented, but not in proportion to the rise in prices, as the following figures show:—

	National Savings Bank	Municipal or Private Savings Banks	Total
	Fr.	Fr.	Fr.
1913 . . .	1,818,000,000	4,011,000,000	5,829,000,000
1914 . . .	1,904,000,000	3,909,000,000	5,813,000,000
1924 . . .	3,306,000,000	8,814,000,000	12,120,000,000

If we convert the actual total (12 milliards) to pre-War francs on the basis of the mean exchange in 1924 it becomes less than 3 milliard fr., that is, to a figure below that of 1911. The savings-bank deposits are influenced by the degree of confidence inspired by the national credit at any given time. This applies even to the municipal or private banks, for these also put nearly all their deposits into state funds. Among the lower classes confidence is greatly shaken by the fall in value of state bonds.

It might be supposed that, given the discontent prevailing among the working class, trade unionism would show a great increase, and a study of the official statistics appears to confirm that supposition; 1911, 1,029,000 trade unionists; 1925, 1,846,000 trade unionists.

But these figures are of little value because most of the trade unionists figure only on paper, and also, since the Moscow revolution, trade unionism has been disorganised. Actually it is represented by three organisations more or less hostile to each other.

1. The oldest of all (dating from 1895)—the *Confédération Générale du Travail*, the famous C.G.T., whose secretary Jouhaux is well known. Its effective membership rose from 1,000,000 before the War to nearly 2,000,000 in 1920. As the result of an attempted general strike provoked by unemployment, of which the C.G.T. did not approve, although it dare not disavow it, and especially of the withdrawal of the Communists in 1921 which was inspired from Moscow, the number of its members fell to 400,000. It has recovered since then, mainly through the adhesion of intellectual workers and officials (among whom are 110,000 teachers) and is said to have 700,000 members at the present time. Although it was declared illegal by a legal decision, never put into execution, its programme is reformist rather than revolutionary.

2. In consequence of the schism just mentioned, another *Confédération Générale du Travail* was formed which qualified its title by the additional word *unitaire*, a strange term for dissentients. Its programme is that of Moscow: the dictatorship of the proletariat. This organisation is known as the C.G.T.U. It has not succeeded in rallying more than 200,000 to 300,000 members and will probably return before long to the older organisation.

3. Finally there is the *Fédération des syndicats catholiques* which is not much in the public eye, but is said to be growing since the War.

The co-operative movement, more favourably situated, has grown steadily since the War in France, as indeed in all countries, particularly as regards consumers' co-operation. The reason for this lies not only in the rise in prices, which has forced the middle class as well as the working class to seek means of reducing the cost of living; there is also a psychological reason—reaction against the existing economic organisation. The classic laws of political economy are no longer accepted, and there is therefore a sympathetic public for a new doctrine such as this, which claims to replace competition by co-operation, the law of supply and demand by fair prices, production for profit by production for service, thus abolishing the profiteer.

The following figures show the progress that has been made:—

	Number of Societies	Number of Members	Sales Figures
			fr.
1918	3,280	865,000	317,000,000
1922	4,300	2,330,000	1,747,000,000

It will be seen that the increase in the sales is much less than it appears, for in 1922 the franc had already fallen to 0·27; the 1,747,000,000 therefore represent only 576,000,000 of 1913 francs. But the progress of the movement is shown above all in the development of central organisations and in the growing part which co-operatives play in national and international economic life. The importance of the movement received official acknowledgment at the end of the War in 1918 when the Conseil Supérieur de la Coopération was created and its advice asked on all questions of interest not only to co-operatives, but to consumers generally, just as the Conseil Supérieur du Travail is called in to advise on questions which concern workers.

Agricultural co-operative societies for mutual credit, have also been greatly multiplied:—

1911	3,946 societies	185,000 members
1923	5,212 societies	284,000 members

but their development is to a large extent artificial, being due as it is principally to the loans granted by the state (about 600,000,000 (150,000,000 gold fr.) up to date in 1924). These funds are not taken from the budget, but from the immense profits which the state draws from its partnership in the Banque de France.

As to the industrial producers' societies, the oldest and most typical of all co-operation in France, they comprise within a small ring some 500 societies in all with 30,000 members. The most celebrated, and one which has been visited by co-operators from all countries is the *Familistère de Guise*. The friendly societies, which in their day were the elementary schools of social solidarity, are now rather out of date. Their field of activity, hedged in on the one hand by employers' institutions, on the other by the extension of compulsory state insurance, is becoming more and more limited.

POPULATION

The demographical position of France was already bad before the War, and was bound to be aggravated by a war which robbed the country of the flower of its population. In 1911 the population was 39,605,000; in 1921 it was 39,240,000.

Thus the population has diminished in the course of these 10 years, but the diminution is even greater than it seems; for Alsace and Lorraine, which did not figure in the 1911 returns, are included in the census of 1921. Now these provinces account for 1,719,000 inhabitants, and if we deduct these from the figure of 39,209,518 we are left with a population of 37,521,000 for France as it was before the War. There is therefore a diminution of more than 2,000,000 and this diminution is only too easily explained:—(1) by the number of men killed in the War (1,400,000) and (2) by the fall of the birth-rate during the War.

The sudden rise in the number of births immediately after the War—a familiar phenomenon—was succeeded by a quick drop to the pre-War figure. Fortunately, the death-rate has sensibly diminished, with the result that the annual excess of births over deaths is greater than before the War:—

	Births	Deaths	Excess of Births over Deaths
1911–3 (3 years average)	746,000	724,000	22,000
1922–4 (3 years average)	758,000	679,000	79,000

It is clear that even could this natural increase be maintained over a period, it would take 26 years to replace the 2,000,000 dead or the unborn of the War. The state endeavours to stimulate the birth-rate by grants to families in proportion to the number of children. But it is hard to believe that these premiums will cause many children to be born; they are only a means of giving material aid to the parents of large families.

Happily foreign immigration goes far towards restoring the balance, for the number of immigrants is now far greater than the number of births in excess of deaths. The annual number of immigrants, taking the average over the three years 1922, 1923, 1924 is 290,000. We may suppose then that the coming census of 1926 will give France a population of 40,600,000 inhabitants. This places her fifth among the great European powers. But she has also a population—black, yellow and white—of 50,000,000 to 60,000,000 in her colonies.

III. NATIONAL FINANCE

On the eve of the World War the public finances of France were in a relatively poor condition, a circumstance which has influenced the whole evolution of French finance since Aug. 1914, and was due solely to the indifferent way in which the finances had been handled.

The Budgetary Deficit.—For the three years 1908–10 the national budget showed a total deficit of 147,000,000 francs. In 1911, it is true, there was a surplus of 141,000,000 fr., but in the following year the deficit reappeared. Although the accounts of the year 1912 show an apparent surplus of 112,500,000 fr., this was only obtained by including 153,000,000 fr. which were extraordinary resources of the Treasury arising from the "Compte provisionnel." In reality this apparent surplus masked a deficit of 40,500,000 francs. For 1913 the budget showed the following results:—

	fr.
Receipts	5,066,900,000
Expenditure	5,038,100,000
Surplus	28,800,000

But the receipts included 172,000,000 fr. again coming for the "Compte Provisionnel," so that the real deficit on the budget was 143,000,000 francs. When the budget for 1914 was under discussion the deficit was estimated at 800,000,000 francs. In reality these deficits were even larger, as a number of items of expenditure which should have been included were withdrawn from the budget by accounting devices. A bad example had been set by the law of Feb. 17 1898, which instituted the special Treasury account for the improvement of military equipment.

Jan. 1 1914 there were still 173,000,000 fr. of short-term ıds issued in virtue of this law, of which 11,000,000 fell due in 4, 124,000,000 in 1915 and 38,000,000 in 1916. A subsequent of March 30 1912 created the account for the improvement naval equipment and, although annual sums were allotted m the budget for this purpose, the expenditure over the five rs 1912–6 exceeded the allocation by 139,293,000 francs.

These extra-budget expenditures, which had become to some ent both regular and normal, were not the only ones. The lomatic tension at the time of the Agadir incident in 1911 l drawn the attention of the French Govt. to the inadequacy the military equipment of France, and caused it to embark very considerable expenditure without the formal authorisa- n of Parliament. In 1912, 22,000,000 fr. were spent in this y but in 1913, owing to the passing of the three-year military vice law, the figures rose to 300,000,000 fr., and in 1914, 488,- ,000 fr. extra-budget credits were estimated for the army d 128,000,000 for the navy.

The "Compte Provisionnel."—In order to hide, at least in part, deficit, the "Compte Provisionnel" was created by the law Feb. 20 1912. This was a treasury device which enabled any plus to be carried over from one financial year to the next; us violating the fundamental rule of an annual budget. Dur- the first year, in 1912, a sum of 159,000,000 fr. was paid into "Compte Provisionnel," arising from the anticipated repay- ent by the Compagnie des Chemins de Fer de l'Est of advances ide to it by the state as a guarantee of interest. In the follow- year it was credited with 141,000,000 fr., the surplus of the ancial year 1911 and with a further 31,000,000 fr. from non- urring sources. In 1914 it received 112,500,000 fr., the surplus the financial year 1912.

The Reform of the Tax System.—Treasury expedients of this pe, besides being inadequate, did not provide a solution, which is clear could only be found by voting the necessary taxes, as as demanded by M. Poincaré when Minister of Finance in 1906. iere were two obstacles in the way of this solution: firstly, the ual unwillingness of all politicians to impose new burdens their electors—an unwillingness which from 1904 to 1914 evented the French Parliament from voting more than 6,000,000 fr. of new taxes as against additional expenditure of 777,000,000 fr.; secondly, the political battle which raged round e question of reform of direct taxation. After prolonged con- oversy, which dated from the reform proposals of M. Caillaux 1907, the law of March 29 1914 was passed, which provided r the reorganisation of the tax on property not built over and r the increase of the tax on income from securities. But this did t bring in any additional revenue, because at the same time e former tax was lowered by an amount equivalent to the eld of the new taxes on securities. On the eve of the declara- on of War, however, a decisive step towards fiscal reform was ken by the creation of the general income tax. This was a ghtly progressive supplementary tax on incomes levied on at part of the total income in excess of 5,000 francs. This new tax ly came into force in 1915, and therefore could not help to eet the deficit at the moment it was voted.

The Treasury and the Loan of July 1914.—The whole of the rrent and accumulated deficits were covered by an increase of e floating debt, which amounted to about 2,100,000,000 fr. Dec. 31 1913. While the necessity of issuing a loan to fund rt of the floating debt was realised as early as 1913, the measure as delayed by a controversy over the question whether or no e interest on the new rente should be exempt from taxation. nally, in June 1914, a law was passed authorising the issue of loan of 805,000,000 fr. of 3½% redeemable rente subject to xation and issued at 182 fr. for each 7 fr. of rente. The sub- ribers were only required to pay down 20 fr. on allotment of a minal 200 fr. of loan, the balance being payable in three sub- quent instalments. As a result of this mode of subscription e loan was chiefly subscribed by the banks, who hoped later dispose of the shares at a profit to the public. To sum up, e following was the financial situation in July 1914, on the e of the War: a considerable budget deficit; a relatively large floating debt; a loan recently issued and taken up by the banks but not placed with the public and involving a heavy burden on all credit institutions on the declaration of War.

FRENCH FINANCE DURING THE WAR (1914–8)

The Declaration of War and the Credit Crisis.—The outbreak of War brought with it a very grave credit crisis, of which the first manifestation was a panic on the Stock Exchange in the last days of July 1914. The settlement of future transactions was suspended for the time being, and on Sept. 3 the Bourse was closed. Hence the funds advanced to speculators to support their forward transactions were locked up, and ceased to be available for industry and commerce. The banks were forced to rediscount bills with the Bank of France, whose holdings of commercial bills rose from 1,554,000,000 fr. on July 25 to 4,000,000,000 fr. on Aug. 4. The Bank of France raised its discount rate from 3½ % to 6 %, and its rate for advances from 4½ % to 7 %. On July 31 the settlement of all commercial liabilities was postponed, and on Aug. 1 a moratorium was proclaimed for the deposits of the banks except for small sums not exceeding 250 francs. The Bank of France never refused to rediscount bills; therefore it seems questionable whether the moratorium was really unavoidable for the other banks. The crisis, though very acute during the first weeks of the War, was not of long duration. The Bourse was reopened on Sept. 27 for spot transactions, and, with the aid of a loan of 200,000,000 fr. from the Bank of France, it proved possible by Sept. 30 1915 to liquidate all commitments carried over during the moratorium, including the loan of 805,000,000 fr. of July 1914. The commercial moratorium was of longer duration. Most of the bills of exchange, etc., maturity of which had been prolonged were taken up by the Bank of France, whose holdings of these securities reached their maximum of 3,977,000,000 fr. on Dec. 24 1914. Many of these bills were relatively quickly absorbed, and their total fell to 1,938,000,000 fr. by the end of 1915. Owing to this credit crisis it was necessary to wait till the end of 1915 before the first big consolidated loan could be issued.

War Expenditure.—The following table summarises the growth of French expenditure for the War:—

Expenditure (Millions of Francs)

	Military Charges	Public Debt	Civil Services	Recoverable Expenditure	Special Accounts	Total
1914	6,526	1,360	2,005	372	108	10,371
1915	14,712	1,818	2,479	1,914	1,197	22,120
1916	23,853	3,327	2,817	2,947	3,904	36,848
1917	28,662	4,816	4,119	4,081	2,983	44,661
1918	36,120	7,021	5,443	5,952	2,113	56,649
	109,873	18,342	16,863	15,266	10,305	170,649

The item "recoverable expenditure" covers that expenditure for which Germany was rendered liable by the Treaty of Versailles. The item "special accounts" comprises the deficits of the special services of the Treasury which were created during the War, and which include extra-budget expenditure, advances to Allied Governments, cession of material to foreign Governments, feeding of the civilian population, etc.

Taxation.—The budget revenue raised during the War amounted to 26,200 million fr., or about 15 % of the total expenditure. When France is reproached with not having made a more considerable fiscal effort it must be remembered that she was deprived by invasion of about one-fifth of her tax revenue. Mobilisation caused the greater part of her labour to be called up, and withdrew many of the financial officials. Further, it is untrue to say that fresh taxes were not voted during the War; the general income tax was increased on three occasions, in 1916, 1917 and 1918, and carried from 2 % to 20 %; in 1917 the old direct taxes were replaced by the new system of income-tax schedules; taxes on succession, stamp duties and taxes on insurance were increased; finally, in 1916, an extraordinary tax on exceptional War profits was imposed. Additional taxation brought in about 2,800 million fr. during the War, and tax revenue rose from 4,100 million fr. in 1915 to 6,800 million fr. in 1918.

Advances of the Bank of France.—The following table shows the total of advances authorised to be made by the Bank of France and of advances actually given:—

	Total Advances Authorised (000,000 omitted)	Total Advances Made (000,000 omitted)
	fr.	fr.
Dec. 31 1914	6,000	3,900
Dec. 31 1915	9,000	5,000
Dec. 31 1916	9,000	7,400
Dec. 31 1917	15,000	12,500
Dec. 31 1918	21,000	17,150

To this total 3,750 million fr. must be added for loans granted by the French Govt. to foreign governments.

The French Exchange and Foreign Loans.—Prior to Aug. 1915 the French exchange, in spite of a deficit in the balance of trade amounting for eight months to 1,600 million fr., was kept at or very near par, thanks to the falling due of foreign coupons, to the export of small quantities of gold, to the placing of £12,000,000 of Treasury bills on the London market, and to an American advance of $10,000,000. Between April 1915 and April 1917 the total deficit of the French balance of trade rose to 27,000 million francs. This deficit was covered partly by expenditure incurred by the British Expeditionary Force in France, partly by the sale of a portion of the French holdings of foreign securities, but chiefly by British and American credits. France sent gold to London to the value of 2,840 million fr. and obtained credits in exchange to the value of 9,000 million francs. At the same time she procured credits amounting to $650,500,000 from the United States. By these means the depreciation of the franc was kept within reasonable limits. On March 31 1917 the franc was 11 % below par in relation to the dollar, 13·5 % in relation to the Swiss franc, and 21 % in relation to the peseta and the Swedish krone.

In April 1917 the United States entered the War, and from then onwards its financial assistance was very great. Between April 1 1917 and Dec. 31 1918 the French balance of trade showed a deficit of 32,000 million fr. which was mainly covered by credit operations; £290,000,000 were placed at the disposal of France by the British Treasury, and $2,500 million by the American Treasury. Smaller loans were also contracted in other countries, *e.g.*, 100,000,000 gold pesos in Argentina, 350,000,000 pesetas in Spain, 100,000,000 yen in Japan, etc. As a result of this assistance the French exchange at its worst never fell more than 44·7 % below par in relation to the Swedish kroner and 39·1 % in relation to the peseta, while on Dec. 31 1918 the depreciation was not more than 9·5 % and 7 % respectively.

Internal Loans.—The principal medium for the transfer of funds to the Govt. for War purposes was the National Defence Bills devised by M. Ribot and issued in virtue of the decree of Sept. 13 1914. These bills were Treasury securities with a currency of one year, six months, three months and even one month after April 1918. They were repayable at par, and could be discounted at the Bank of France within three months of maturity. They could be crossed like cheques. In fact, they acted as deposits with the Treasury which could very easily be mobilised. In view of their convenience and elasticity they quickly proved a great success, and the Treasury succeeded by this means in mobilising a considerable part of the available funds of the nation for its requirements. The National Defence Bills had, however, one danger—the abnormal expansion of the floating debt. To retard the increase of the floating debt the French Treasury made successive issues of National Defence Bonds with a currency of 10, 6 and 5 years.

Finally, when the credit crisis referred to above had been overcome, the state decided to issue a series of irredeemable loans—the 5 % loan of 1915 (real rate 5·73 %); the 5 % loan of 1916 (real rate 5·71 %); the 4 % loan of 1917 (real rate 5·83 %); and the 4 % loan of 118 (real rate 5·68 %).

Table Showing Loans Raised by France
(In millions of francs)

	1914	1915	1916	1917	1918
Irredeemable Loans (net yield)	..	6,265	5,425	5,174	7,246

National Defence Bills and Bonds	1,858	10,487	12,955	13,054	16,611
Funds deposited at the Treasury	..	...	53	360	436
Total	2,323	16,752	18,433	18,588	24,293

French Finances from 1919 to 1926

At the end of the War France was faced with three very grave financial problems—the liquidation of the War; the reconstruction of the devastated regions; and the reorganisation of her fiscal system on an entirely new basis. The liquidation of the War involved heavy outgoings in respect of unexpired contracts, extraordinary civil expenditure, the progressive liquidation of the special accounts of the Treasury, etc., which were not completed till the end of 1921, and may be estimated at about 36 or 37,000 million francs. The reconstruction of the devastated regions was regulated by the law of April 17 1919. This law, which was voted at a time when everyone believed that Germany would make good the whole of the damage in accordance with the provisions of the Treaty of Versailles, was conceived in a very liberal spirit. It laid down that all those who had suffered loss were entitled to an indemnity fixed by a special *ad hoc* body, and equivalent to the pre-War value of the property. If, further, the victim undertook to reconstruct his destroyed property he had a right to the refund of additional expenses caused by the rise in prices. The total cost of reparation thus calculated is e mated at 82,000 million francs. In addition to this there must added the permanent increase in expenditure resulting from hi prices and salaries and the service of the debt.

The story of the French financial effort since 1918 falls natura into four periods: (1) the year 1919; (2) 1920–1; (3) 1922–Ju 1924; (4) June 1924–Jan. 1926.

1919 and the Period of Inflation.—The events of the year 19 weigh heavily on the financial destiny of France. At the end Dec. 1918 the English pound stood at 29·97 fr. and the dollar 5·45 francs. At the end of Dec. 1919 the pound sterling was valu at 41·48 fr. and the dollar at 11 francs. This fall was due to t persistent deficit in the balance of trade (24,000 million fr. in 191 The deficit was again met in part, as in previous years, by forei credits. But on Jan. 3 1919 the British Treasury announced that would make no further advances to the French Treasury, and Dec. the American Treasury followed suit. Nevertheless, the ext nal debt of France increased in 1919 by about 11,000 million fran The expenditure of the state, swollen by the accompanying inflati amounted to 54,200 million fr. scarcely less than in the last year the War. This total included 15,500 million fr. of "recoveral expenditure," comprising costs of reconstruction and War pensio Budget revenue, on the other hand only amounted to 11,600 milli francs. The Chamber of Deputies elected in 1914 could not make its mind to impose new and heavy taxes on the eve of a new electio As a result the floating debt increased in 12 months by 27,653 milli francs. The Crédit National, created specially for the finance of t devastated regions, raised a loan at the end of 1919 which brought 3,960 million francs. Finally the Treasury borrowed 8,370 milli fr. from the Bank of France—a larger sum than in any year of t War. It was this wholesale inflation which put the seal on the d preciation of the franc.

During the year 1919, which could and should have been the fir year of financial reconstruction, the financial methods of the W were merely perpetuated, under the direction of the Finan Minister, M. Klotz. Financially the War did not finish till the e of 1919. In six years the Treasury had spent 224,000 million f which were raised in the following way:—

	fr.
Taxation	38,000,000,000
Internal Loans	112,000,000,000
Foreign Loans	44,000,000,000
Advances from the Bank of France	30,000,000,000
Total	224,000,000,000

Deflation (1920–1).—During 1920 and 1921, when MM. Françoi Marsal and Doumer were at the Ministry of Finance, there was a effective reaction against the methods of the preceding years. O Jan. 13 1920 the estimates for the current year were laid before th newly elected Chamber. The estimates provided for 17,861 millio fr. of ordinary and 7,568 million fr. of extraordinary expenditur the former was only covered by normal revenue to the extent 9,368 million fr. and the latter to the extent of 3,000 million f yielded by the sale of War stocks. To this budget deficit of 13,00 million fr. must be added the final deficits of the special accounts the Treasury (which in 1920 amounted to 5,092 million fr.) and further 22,000 million fr. of credits for "recoverable expenditure, which after July 1920 appeared under the heading "Special Budg of Recoverable Expenditure," and continued till 1925. In actu fact the expenditure was greater than had been anticipated, an amounted to 58,100 million francs. In June 1920 additional taxe to bring in 7,752 million fr. were voted to balance the ordinar budget, the normal revenue being thereby increased to 20,10 million francs. There still remained, however, a deficit of 38,00 million fr. which was covered by loans. A 5% long-term loan wa issued in Feb. March 1920, and a 6% loan in Oct.–November. Th total subscriptions to these two loans were 43,000 million fr., o which more than 18,000 million fr. were new money, the rest consisting of conversions of former loans or of floating debt. In 1921 th financial situation was further improved. The total expenditur was reduced from 58,100 million fr. in 1920 to 51,000 million fr., an revenue rose to 23,100 million francs. The deficit fell to 28,00 million francs.

The following table summarises the Treasury operations durin these two years:—

I. *Expenditure*
(In millions of francs)

	Military Charges	Debt	Civil Service	Recoverable Expenditure	Special Accounts	Refunds to Bank	Total
1920	7,600	11,700	11,400	22,300	5,100	..	58,100
1921	6,000	11,100	9,900	21,400	2,700	2,100	53,200

II. *Receipts*
(In millions of francs)

	Budget Revenue	Internal Loans	Advances from the Bank of France	Total
1920 . . .	20,100	38,400	500	59,000
1921 . . .	23,100	29,700	..	52,800

In the years 1920 and 1921, despite the very large deficit, the financial situation was easier. It proved possible not merely to stop inflation, but to inaugurate a systematic policy of deflation. The chief author of this courageous policy was M. François Marsal, who was Minister of Finance in 1920, and who in June 1920 carried through he imposition of 8,000 million fr. of new taxation; in addition he consolidated more than 12,000 million fr. of floating debt, and in Dec. made the agreement with the Bank of France by which he state undertook to repay 2,000 million fr. annually. The exchange also benefited by this policy. The dollar, which had risen to 7 francs in 1920, fell to 12·50 francs in June 1921, and even as low as 11 francs in April 1922. Wholesale prices fell more than 40% as compared with the spring of 1920.

The Budget Deficit and the Exchange Crisis of 1924 (Jan. 1922–May 1924).—Throughout 1922 and 1923 the franc depreciated in value, and at the end of 1923 the dollar was worth more than 19 rancs. This was due to several causes, and undoubtedly questions of foreign policy—the discords amongst the Allies on the subject of reparations and the Franco-Belgian occupation of the Ruhr—played heir part. But the basic reason is to be sought above all in the inancial situation of France herself. State expenditure, which, hough slowly decreasing, remained very large, was divided into hree big groups—the general budget, to be met out of taxation; the special budget of "recoverable expenditure" (pensions and interest on reparations debt), which in theory should be met by Germany; and the costs of reconstruction, which quite properly were covered by loans. The results are shown by the following figures:—

	General Budget (in millions of francs)		Special Budget (in millions of francs)	
	1922	1923	1922	1923
Expenditure . . .	24,688	24,163	9,905	10,382
Revenue	23,382	24,202	160	109
Balance	−1,306	+39	−9,745	−10,273

Hence the total budget deficit amounted in 1922 to 11,051 million fr. and in 1923 to 10,234 million francs. These deficits were covered by loan operations, and the state was even able to reduce the total of the advances from the Bank of France from 24,150 million fr. to 23,100 million francs. It was, however, becoming increasingly difficult to raise long-term loans. The Crédit National was alone in being able to place a loan with the public of 5,000 million francs. The rest of the expenditure was covered by an increase in the floating and short term debt. This situation was soon reflected in the movement of the foreign exchanges. There was a violent crisis at the beginning of 1924, and the pound sterling rose from 85 fr. to 117 fr. and the dollar from 19·60 fr. to 27·20 fr. on March 11. This crisis was the result of intensive speculative selling which developed in continental centres such as Vienna, Berlin, Milan, Basle and Amsterdam, and was in a large measure artificial. None the less it revealed how precarious was the financial situation of France. Under the energetic direction of M. Poincaré, the Prime Minister, a great effort was made to retrieve the position. The Govt. asked Parliament to vote 6,000 million fr. of taxes in order to cover the expenditure of the special as well as of the general budget, and it asked for powers to cut down expenditure by 1,000 million fr. by administrative decree. These measures were voted by the end of March 1924. At the same time exchange credits were raised in London and New York, and on April 20 the pound had fallen to 65 fr. and the dollar to 14·80 francs.

The Elections of May 11 1924 and the Return of Inflation.—The new elections resulted in the victory of the parties of the Left, which had refused to vote the last fiscal measures proposed by M. Poincaré. The Socialist party had a good deal of influence in the new Govt., and its revolutionary programme disquieted the propertied classes of the country. The budgetary equilibrium which had only just been restored was again destroyed, for the new Chamber voted 1,700 million fr. of supplementary credits, and suspended the realisation of the 1,000 million fr. of economies adopted by the preceding Chamber. There was thus a deficit of 3,000 million fr. on the budget of 1924. This deficit was enhanced in 1925 by the increase of 1,405 million fr. in War pensions, by the increase of the salaries of officials, and by expenditure in Morocco and Syria. The situation was aggravated by the falling due of quantities of bills and short-term bonds, of which about 8,000 million fr. had to be paid off in 1925. To this figure must be added the deficit in the subscriptions to the National Defence Bills, the amount of which reached 9,000 million francs. To meet these liabilities the Treasury issued, in Nov.–Dec. 1924, 5% Treasury bills at 150 repayable in 10 years (effective rate 9·20%), and in July–Oct. 1925 an irredeemable 4% loan with an exchange guarantee. These two loans brought into the Treasury a nominal sum of 11,000 million fr., but in fact very much less, because the greater part of the subscriptions only represented the consolidation of the floating debt.

It was under these conditions that France returned in 1925 to the *régime* of inflation, for the first time since 1919. In April 1925 the state asked the Bank of France for 4,000 million fr. of new advances, in June for a further 6,000 million fr., in Nov. for 1,500 million fr., and in Dec. 1925 for 6,000 million francs. All these credits were not in fact exhausted. Nevertheless, at the beginning of 1926 the advances from the bank to the state had risen from 22,000 to 36,000 million fr., and the total of notes in circulation from 40,500 to 52,000 million francs. Parallel with this the French exchange continued to fall, and the pound sterling, which was worth 88 fr. in Dec. 1924, exceeded 130 fr. in Dec. 1925. At the beginning of 1926 the position was as follows. The budget, with a total expenditure of 37,200 million fr. (the general budget and the special budget were amalgamated in 1925), shows a deficit of 4,500 million francs. Part of this deficit was covered by 3,000 million fr. of new exceptional revenue voted on Dec. 4 1925. All parties were agreed as to the necessity of creating a sinking fund to consolidate the floating debt. Successive Ministers of Finance, M. Doumer and M. Raoul Péret, proposed new taxes amounting to nearly 5,000 million francs.[1]

The French Debt and the Work of Reconstruction.—To have a sound understanding of the financial situation and its handling since 1918 it is desirable to relate the debt to the effort made for the reconstruction of the devastated regions. The two following tables show—(1) the situation of the French internal debt on April 30 1925; (2) the expenses devoted to the reparation of War damage to Dec. 31 1924.

I. *French Internal Debt*

	Annual Charge	Capital Debt
Perpetual and Long-term Debt	7,451,232,802	155,252,268,681
Short-term **Debt**	2,692,869,140	44,274,769,000
Floating **Debt**	2,762,584,000	86,646,656,500
Total	12,906,685,942	286,173,694,181

II. *Expenses Resulting from Reparation of War Damage*
(In millions of francs)

Damage to Persons	Private Property	Railways, Public Property, and Costs of Administration	Interest paid on Indemnities	Interest on Loans Contracted	Total
36,436	59,283	12,760	2,594	19,000	130,073

In conclusion, 45% of the internal debt of France comes from expenditure for the reparation of War damage, and one-sixth of the French budget was devoted in 1926 to the service of this debt.

BIBLIOGRAPHY.—Reports of the Rapporteurs of the Finance Committees of the Chambre des Députés and of the Sénat, published as supplements to the *Journal Officiel; Reports on the Economic and Industral Conditions in France* (annual, Stationery Office, London). *Effect of the War upon French Economic Life*, ed. C. Gidé, (Carnegie Endowment for International Peace, 1923). (E. MI.)

---

[1] The crisis in the franc was due to a loss of confidence, which showed itself in a reluctance on the part of the public to invest in the floating debt. M. Loucheur, while Minister of Finance in Dec. 1925, obtained a measure imposing a special additional income tax (non-recurrent); and steps were taken to hasten the collection of the ordinary income tax. The "heavy revenue collections" thus obtained were sufficient to meet all needs in the opening months of 1926. The At last, M. Raoul Péret, procured the passage of a budget which balanced at 37½ milliards, with a surplus of 250 millions, additional taxation to the amount of 4¼ milliards being imposed.

But meanwhile the exceptional revenue receipts of Dec. and Jan. could not continue, and a further block of three milliards of maturing bonds had to be met early in May. The exchange began to give way and rose above 140. The outbreak of the general strike in England at the beginning of May was the signal for something like an exchange panic, and after wild fluctuations, in the course of which the exchange reached 176, the French Govt. intervened with support, and brought it back for the moment almost to 140. At the beginning of June M. Péret appointed a committee of French financial experts to make recommendations for the future. (Ed. *E.B.*)

IV. DEFENCE

National defence in France underwent some material modifications after the World War. The reforms were based on the somewhat conflicting demands of national economy and of national security against aggression. In practice they resolved themselves as follows:—

(1) army and navy, in time of peace, to be limited strictly to the scale necessary for covering national mobilisation in case of aggression and allowing that mobilisation to be carried out at a speed compatible with that of the said aggression; the colonies and the communications with overseas possessions to be safeguarded; and

(2) the general organisation of the nation in war time to be minutely worked out.

Conscription.—Compulsory personal service was therefore maintained, but the duration was reduced to 18 months (Act of April 1 1923). The following tables show the effectives and the budgets of 1925 compared with those of the preceding years:—

	Aug. 1 1914 Pre-War	Aug. 15 1914 after Mobilisation	Nov. 1918 Armistice	1925
Army				
Effectives (French and Colonial)	947,000	3,850,000	4,200,000	695,000
Inf. Divs	44	87	112	32
Cav. Divs	10	10	6	5
Field Guns	2,800	4,044	5,000	1,350
Heavy Guns	250	308	5,100	1,000
Air Force				
Number of Aeroplanes	120	120	4,700	1,850
Navy				
Effectives	69,000	100,000	174,000	56,000
Battleships	26	26	10	9
Cruisers	31	31	15	18
Aeroplane-carriers	..	..	..	1
Destroyers	..	..	2	8
Torpedo-boats	83	83	51	63
Submarines	72	72	33	66

National Defence budgets (including gendarmerie, military, naval and colonial aviation, and certain expenses connected with public works undertaken in the interests of the army):—

In Millions of Gold Francs

Year	Army	Navy	Colonies	Total
1914	1,720	513	92	2,325
1925	955	308	50	1,313

General Organisation of National Defence.—The lessons of the War showed the necessity of a general organisation of the nation in readiness for war-time, the object of which should be to prepare in advance the mobilisation of civil and military forces alike to organise the nation's entire economic and industrial resources, etc. A bill to this effect was laid before Parliament on July 7 1925.

The general direction of a war devolves upon the Government. To assist the Govt. in their task, consultative and research bodies are placed at their disposal in war-time and also, for the purpose of advising upon the necessary precautions to be taken in peacetime. These are: the *Conseil Supérieur de la Défense Nationale,* composed of the appropriate ministers; the *Commission d'Études* of that council (composed of the highest functionaries of the various ministries), and the General Permanent Secretariat. The actual conduct of operations remains the exclusive province of the commanders-in-chief of the military and naval forces.

The Army

The army proper is formed by calling up the reserves. The permanent army is but the nucleus; its functions are: to train contingents as they are called up; to protect overseas possessions; to prepare for mobilisation and, in case of aggression, to protect the frontier while mobilisation is proceeding.

The recruiting Act of April 1 1923 provides for:—

(1) an active army, formed by:—

the calling-up of recruits, all young men who have reached the age of 20 being obliged to serve for 18 months; half of the contingent is called up in May, half in November;

voluntary enlistment (engagements, re-engagements, commissions) by which lower professional cadres, necessary both in peace and in war, are formed; and

auxiliary or reserve cadres.

(2) a first reinforcement (*disponibilité*) in which the citizen is reckoned for a period of two years following his term of active service; in case of need he is liable to be recalled;

(3) a first reserve, for use also on active service in which the citizen serves 16½ years, and a second reserve to which he is posted for 8 years; this reserve is designed for local services and work in industrial mobilisation.

The duration of service is reduced to one year for eldest sons of large families (minimum of 5 children). Special advantages are accorded to prospective reserve officers who have followed the military training course with success.

The 695,000 men of the fighting troops (France, countries of occupation, colonies) which constitute the army are thus distributed:—

French (1½ contingents of conscripts and professional soldiers)	457,000
Foreign Legion	14,000
North-African natives	97,000
Native colonials	62,000
Irregulars and auxiliaries	16,000
Gendarmerie and Republican Guard	29,000
	695,000

Out of this total of 695,000 men, only 395,000 are serving in France; the remainder—some 300,000 men—are engaged on the Rhine, in Algeria, Morocco, the Levant and the various colonies.

Organisation of the Army.—The Act dealing with the constitution of cadres and strengths which had passed the Chamber of Deputies but has not, at the end of 1925, been discussed by the Senate, distributed these effectives between the various arms and services. Pending the final passing of the Act, the Minister of War was authorised to proceed with re-groupings by which the army was reconstituted as follows:—

Large Units, 32 divisions of infantry of which 5 are on the Rhine; 5 divisions of cavalry of which 1 is on the Rhine.

Redistribution of Troops.—The following table gives the proportionate distribution between the various arms on mobilisation in 1914, at the Armistice, and in the army of today:—

Arms and Services	Aug. 1 1914	Nov. 1918	1925
	%	%	%
Infantry	65·6	43·7	53·8
Tanks	·0	0·6	1·8
Cavalry	9·0	3·5	8·0
Artillery	16·1	27·4	16·6
Engineers	3·0	8·0	5·2
Air Force	0·3	3·3	4·1
Transport	1·3	7·7	3·4
Administrative Services	2·3	5·2	3·0
Gendarmerie	2·4	0·6	4·1

This table shows the extent to which those arms employing principally mechanical weapons (tanks, artillery) have developed.

In accordance with the experience gained from the War, the army is being organised and trained on the basis of an increase in all arms of fire-power.

The Navy

During the War.—While hostilities were proceeding, the French Navy underwent a considerable reduction, both on account of War losses and of the obligation under which it stood to devote the greater number of its arsenals and private workshops to satisfying the needs of the army.

The tonnage of 1914 and that of 1919 are as follows: 1914, 816,000; 1919, 590,000.

The falling-off is therefore considerable and it becomes more striking if the heavy wear of the ships still in service—particularly the small vessels—be taken into account.

ince the War.—From the end of the War up to 1921 the French ry has had to pay for a great many special expenses of its , inevitably arising out of War-time necessities. Thus bur- ed, its budget rose to 1,962,000,000 gold francs in 1919 as nst 515,000,000 in 1914 and a yearly average of 813,000,000 ng the War. As it was impossible to put any further strain he exchequer, the reconstruction of the fleet, which continued lecline in tonnage (falling, in 1924, to 394,000), had to be yed. At Washington, in 1922, France consented to the pro- d reductions, according to which the total tonnage of her tal ships might not exceed 175,000 tons.

'he building of battleships was postponed. With a view to ecting the country's vital communications, particularly in Mediterranean and the North Atlantic, the French Navy ied its attention to the use of submarines, aeroplanes and t vessels with protected bases. Light cruisers and submarines e laid down as follows: in 1922, 3 cruisers of 8,000 tons, 6 royers, 12 torpedo-boats, 12 submarines, 1 aeroplane-carrier se units are nearly ready); in 1923, 9 submarines; in 1924, 2 sers of 10,000 tons, 6 torpedo-boats, 2 submarines; 1 cruiser o,000 tons, 3 destroyers, 4 torpedo-boats, 9 submarines (of ch two are mine-layers), 1 surface mine-layer and 1 aircraft sport are to be proceeded with at once. This represents an emely modest effort; the naval budget has not exceeded a l of 330,000,000 gold francs on an average, from 1921 925.

'he Future.—The schemes for the future of the French Navy e been dealt with in three bills which are still (1926) under sideration. The high-seas fleet, exclusive of special vessels, ld consist of: battleships up to 175,000 tonnage, aeroplane- rying vessels up to 60,000 tonnage, in conformity with the shington Treaty; in addition, 360,000 tons of light vessels isers, destroyers and torpedo-boats) and 90,000 tons of sub- rines. Age-limit: battleships and aeroplane-carriers 20 years; isers 17 years; destroyers and torpedo-boats 15 years; sub- rines 12 years. The naval air force would be composed of 50 hts of aeroplanes, of which 35 are fully equipped and aircraft various kinds (dirigibles, captive balloons, etc.) varying in nber.

'or coast defence there would be coast flotillas of submarines, st patrols, mine-sweepers, mine-layers, etc.; artillery, obstacles, ection systems, aeroplane service and, finally, troops and er means, controlled by the War Office, which will be placed the disposal of the navy. Although no term has been fixed the execution of this programme, the Dept. of Marine intends nave it completed within 20 years.

THE AIR FORCE

There is in France no organisation analogous to the British Ministry. A certain amount of centralisation has been ieved however as regards technical research, which is under authority of the Under-Secretary of State, who is also respon- le for preparing the mobilisation of aircraft industries.

A comparison of the numbers in 1914 and in 1918 shows the effort that was made in the War. During the 4 years 40,000 new aeroplanes and 92,000 engines were constructed.

Evolution of the Air Force, 1914–25

eronautic Section	Aug. 1 1914		Nov. 1918		1925			
	Army	Navy	Army	Navy	Army	Navy	Colonies	Civil Aviation
viation								
No. of flights	23	0	322	0	130	11	3	
No. of machines	120	8	3,430	1,264	1,500	389	30	700[1]
alloon Service								
o. of captive balloons	12	0	77	190	18	21	..	..
o. of dirigibles	8	0	0	37	..	13	..	..

200 are for training purposes.

The increase in the total of the four budgets (military, naval, colonial and civil), which rises from 367,000,000 fr. in 1920 to 791,000,000 fr. in 1925, may be put down to the necessity for replacing *matériel* (some of which dates back to the War) and above all to the expenses connected with building and preparation of the aerodromes and landing grounds. This budget would, if expressed in pounds (at 120 francs) amount to £6,600,000.

Organisation of Military Air Force.—The 130 squadrons of the military air force are distributed in 14 regiments and five autonomous groups. Two regiments of the balloon service deal with captive balloons. Nine of those regiments are formed in division and constitute the two air divisions.

Organisation of the Naval Air Force.—The naval air force, a War creation, is undergoing reorganisation. Its final status is defined by a bill which was still under consideration at the end of 1925. The 11 squadrons of the naval air force were at that time distributed between different centres (Cherbourg, Brest, Saint-Raphaël, etc.).

France was spending, in 1925, 44%[1] less on national defence than in 1914. The national defence budget, in which certain expenses figure, which in many countries fall upon budgets other than those of the army and navy, represented in 1914 44% of the general budget; in 1925 it represented only 17% of it. In her deep desire for peace France reduced her military expenses to the utmost extent and only hopes to effect still greater reductions. In that spirit she has made every effort to assure safety by putting into practice the pact of the League of Nations and furthering the development of arbitration and ideas of international solidarity. See *Armaments Year Book* (League of Nations, 1926) where the references to decrees on national defence are given. (B. S.)

V. INVADED REGIONS

In 1917 and 1918 when French ministers visited the Front they often wondered if it would ever prove possible to repair the dreadful ruin accumulated under their eyes. At Lens, for instance, the magnitude of the disaster was overwhelming. Not a house standing, 101 great pithead super-structures overthrown, their iron carcasses lying twisted on the ground, everywhere a terrible confusion of bricks, tiles, remnants of furniture—in one word, chaos. In the coal-mines, all the galleries flooded, the apparatus removed, the efforts of three generations completely annihilated. To-day there is hardly a trace of ruin, Lens is a city of wide streets and comfortable houses, the new arrangements of its mines are excellent; and the production of coal is equal to and even greater than that before the War. How could all this be brought about?

Extent of the Losses.—First, a few figures. When the damage was catalogued at the time of the Armistice, it was discovered that 289,000 houses had been completely destroyed and over 400,000 more or less damaged. Nearly 2,000,000 hectares of land had to be restored for cultivation. More than 6,000 factories had been destroyed or emptied of their machinery. The monetary value of these losses was about £1½ milliard; to reconstruct them (assuming the work to cost 3 times as much as before the War) 110 milliard gold francs would be required. Immediately after hostilities had ceased, M. Clemenceau abolished the Ministry of Munitions, replacing it by the Ministry of Reconstruction, of which the present writer was in charge. The new ministry first dealt as quickly as possible with those factories where the buildings and part of the machinery still remained and hastened to equip them to employ the industrial population. There were 500,000 unemployed; a year later unemployment had practically disappeared; the workmen had restored the factories, which had been hurriedly got going and were clearing away ruins and beginning reconstruction. The industrial districts thus received the first attention. This is one of the matters for which the Government has been most severely criticised; but it was the logical course, and as events showed, the right one.

---

[1] This figure is based on the changed value of the franc.

In restoring the soil itself, in rebuilding the farms and enabling those fertile lands to resume the production of the wheat urgently required by the rest of France, the inhabitants themselves assisted in an amazing degree. The French peasant is deeply attached to the soil; he returned to it as soon as he could. He found it covered with shells, with strands of barbed wire, with block-houses. He found his home and farm buildings in ruins. Not for a moment did he lose heart. He set to work at once, surrounded by difficulties which would have daunted many a brave heart, even by grave dangers; so many unexploded shells remained that between 1919–24 more than one person a day, on an average, was killed in unearthing them. Nothing could stop the French peasant. The state helped by granting him little by little, as needed, financial assistance—the sums necessary to rebuild his dwelling and his farm buildings—and found him labour to clear his fields.

A year later, some 90% of the Département du Nord had been restored to cultivation, and in 1923 France's production of wheat had reached its pre-War figures, and of sugar very nearly so. The industrialists too, faced with empty or ruined factories, went bravely to work; but the farmers whose efforts saved France were even more admirable. To-day at least 90% of the farms have been reconstructed. Everywhere, thanks to the good harvests of recent years, prosperity has returned, and the zones where the havoc has so far defied restoration are growing daily smaller, and we may hope that, with rare exceptions, they will disappear altogether. Some reservation is necessary: the surroundings of Verdun are a frightful example of what is meant. As Minister of the Liberated Regions the present writer had to sign the act recording the final disappearance off the map of France of 11 villages of which nothing, hardly a heap of stones, remained. On every square metre there were so many fragments of shells that the whole of this territory might really have been exploited as an iron-mine, but it was useless to think of putting it under the plough. The signature of the act consecrated to death beyond repeal these villages where so many generations had lived, in whose defence so many good men had died.

Building Reconstruction.—The rebuilding of dwellings was a much longer task. Dr. Rathenau, with whom the reparations question was discussed at Wiesbaden, was surprised that the Ministry had not decided to rebuild the towns, not on the old sites, but near by, on virgin fields, constructing regular rows of houses and laying out the plans in the American style. Dr. Rathenau displayed ignorance of the French spirit in supposing that Frenchmen, with their profound individualism, could have adapted themselves to such a system. Each man has chosen the site of his house, he wishes to keep it, to rebuild it in its old place, different in size and shape from that of his neighbours, on his own plan, in his own style. To-day the city of Rheims, which was so completely ruined, is almost entirely restored. It has retained the mark of its old architecture, the houses are on the same spots as before. Some districts, however, of the devastated regions wanted to follow the ideas explained by Dr. Rathenau. The experiment was unsuccessful. Thus there are some large villages with roads which are too straight and too broad, which have not re-assumed their pre-War life. It is a grievous error to attempt to do violence to the psychology of a nation. The reconstruction of landed property is far advanced. In each village so-called "reconstruction co-operative societies" have been established, through which a few devoted men have set themselves to restore the homes of their fellow-citizens. They have lacked means, the parsimony of the last three annual budgets has complicated their task, but little by little, assisted by local loans, their efforts have made headway.

Finance of Reconstruction.—How has all this been paid for? From 1919–22 by loans from the state; but after 1922, financial difficulties grew more pressing and the sufferers from the devastation have been paid to a large extent by state loans redeemable in 10 years, which they have had to get taken up as they could; this has resulted in a serious fall of these bonds. To-day, since the Dawes plan has come into force, it has been possible to spread out the effort over three or four years, and should be about completed by the end of 1928. In 1926 a s equal to about £100,000,000 still remained to be spent. T sum was not large in comparison with what had been spent to date, but it represented a great effort.

Such are the broad outlines of the work of reconstruction the liberated districts. It was successful, thanks above all the united effort of French citizens and thanks to the fact th for several years the whole of France consented to burden h self in order to pay unassisted for the restoration of her rui for it must be admitted with regret—except in a few individ instances, France and France alone has had to shoulder expenditure. The writer does not forget the assistance grant by various British municipalities. In many French villages a towns one may see public rooms or fountains paid for by generosity of British towns. (L. L.)

VI. THE COLONIAL EMPIRE

Description.—The French colonial domain appears at fi sight extremely various and scattered, since there is no contin in which France cannot count her colonies. In fact, it consi of two very different parts. First the remains of the old coloni Saint Pierre and Miquelon, on the Canadian coast; Martiniq and Gaudeloupe in the West Indies, near New Orleans; Guia in South America; five enclaves in British East India, Pon cherry being the most important; Réunion I. in the Indian Oce near Mauritius, a relic of the match between Bougainville a Cook; a series of islands, of which the most important are N Caledonia, Tahiti and the New Hebrides, held in common wi Great Britain. These are, if one likes to call them so, the arist cratic colonies. The American and Indian colonies and Réuni have their deputies and senators in the French Parliame They are united with France by old bonds of affection. Th have given her scholars, administrators and great men of l ters. In certain cases they derive special importance from th situation on the great international routes, or their great r sources. But, above all, their value for France is sentiment and historic; they are the outline of the first empire lost in t 18th century. The colonies of the 19th century on the oth hand, form a homogeneous system. They are divided into t groups, African and Asiatic, both closely concentrated—wi the exception in Africa of Jibuti and Madagascar.

The following table shows the respective importance of t three groups:—

Colony	Area in sq. km.	Population census 1920 1
I. America and Australasia (group of old colonies)	129,491	652,300
II. African group	11,516,224	35,919,405
III. Asiatic group	879,355	22,250,333
	12,525,070	58,822,038
France (for comparison)	550,985	40,000,000

The African group consists of Northern Africa (Alger Tunisia, Morocco); French West Africa (Senegal, Guinea, t Ivory Coast, Dahomey, Niger); French Central Africa, whi stretches from the Congo to Lake Chad and the Nile Basi Madagascar, the third largest island in the world; and the Fren Somali Coast, at the mouth of the Red Sea. In addition, Fran has mandates in Togo and Cameroons. This group, by i proximity, seems specially destined to act as an extension of t mother-country. It is naturally commanded by Northe Africa, which is only 750 km. distant from France, 20 hour journey by sea, or six hours by air. From Northern Africa t railroads and aerial routes spread out towards the tropical a equatorial territories; it links the mother-country and the oth African colonies. Algeria, lying as it does between Morocco a Tunisia, is the pivot of this system, and is rightly consider he key position, whether judged by the number of French hich inhabit it (600,000 out of 800,000 Europeans, against ,000,000 natives) or by the loyalty of its population and their eady acceptance of French culture. Owing to its Mediterranean ituation, Syria, administered by France under mandate, may also be included in this group, although lying in Asia. The Governor of Algeria and the Residents-General in Morocco and Tunisia meet every year in conference in one of the hree capitals in Northern Africa alternately. In 1926, for the first time, the Governor of French West Africa attended this meeting.

The Asiatic group consists of French Indo-China, or the Indo-Chinese Union, including six colonies or protectorates—Cochin-China, Cambodia, Annam, Tongking, Laos and the territory of Kwangchow. This union was organised in 1887. A series of reaties with Siam (the most recent dated 1926) and with China have now regularised its relations with all its neighbours. Indo-China has become the base of French policy in the Far East.

Administration.—The administrative ties which unite these French colonies with the mother-country are very various. There is no central colonial body in Paris. The Conseil Supérieur des Colonies, which consists of a number of persons distinguished in politics, commerce and the arts who are competent o speak on colonial affairs, is merely an advisory body. Plans for uniting under the control of a single body all the different colonies of North Africa, or of Indo-China and the Australasian possessions, have not been realised. Algeria is administered by the Ministry of the Interior; it is divided into departments administered by prefects and sub-prefects appointed by this Ministry and belonging to the home civil service. The protectorates of Tunisia and Morocco and the mandated territory of Syria are under the Ministry of Foreign Affairs, which appoints to them sub-agents from the diplomatic or consular lists, or from a service special to these three countries. The Colonial Ministry is in charge of the other colonies, and the École Coloniale in Paris furnishes their administrators and colonial governors. In fact, even the countries directly subordinate to the Colonial Ministry enjoy a degree of autonomy, and the governors have very full discretionary powers. The reason for this liberal system of administration lies as much in the conditions under which the French colonial empire grew up as in the French temperament. At the moment when explorers or soldiers conquered these domains for France, France did not need them. She had no surplus population requiring an outlet. Agriculturally, she was self-sufficing; industrially, her commerce, which was principally one of luxury articles, found its market in the more highly developed countries. The colonies were therefore subjected to no exploitation, and were often administered by soldiers—that is to say, by the class of ruler who is least interested in economic production. The relations between the administration and the natives were consequently marked by a particularly liberal character. Moreover, the colonies were granted financial autonomy as early as possible. The French colonial estimates have always been meagre—in 1925 only 270,000,000 francs. The financial administration of the colonies did not, therefore, concern French political life, which is essentially parliamentary. Nor was there any rivalry between the careers of the Frenchman—as soldier, official or great landowner or merchant—and the native. Things were different, for example, in Tunis, where the Italian and the native compete with one another. The colonial governors, apt, like all Frenchmen, to apply parliamentary formulae to life, and often themselves parliamentarians, were anxious to develop local councils and local assemblies, even with the power of voting taxes, in the countries which they were charged to administer. Finally, the Frenchman has little race or colour prejudice. All this contributes to give French colonisation the aspect of a friendly collaboration not dissimilar from the method of mandates.

French emigration is not due to the need for economic expansion or to divert a surplus population, but to the need of moral expansion. Missionaries, professors and soldiers form the largest contingent of emigrants. The colonies replace for them fields of action closed to them in Europe or America. Whether in India, China, Madagascar, Tunisia or Morocco, even in the Sudan, the effort of the French administrator has awakened national sentiment in these countries, after putting an end to the civil wars with which they were all torn. Certain races—for example, those of Cambodia—have been saved from a fatal torpor. Archaeologists, painters, and men of letters constitute a relatively high proportion of the French element, and in Indo-China and Morocco, for example, the artistic and intellectual regeneration of the colonised people cannot but strengthen their vitality. The colonial exhibition at Marseilles in 1922 illustrated this method. These considerations explain why France has sometimes been reproached with not having thoroughly exploited her colonial possessions.

Resources in Men and Wealth.—The War led French statesmen to take account of colonial resources in men and material wealth. First, it supported the theories of those who considered that France's military expenses might be reduced by enlisting native troops. The colonies contributed 545,000 combatant soldiers to the French Army. The strength (about 180,000) of the colonial army in 1925 rested mainly on native recruiting. The colonies are also a reservoir for the manual labour in which France is deficient. Many of the 183,928 colonial workmen brought to France during the War remained, and this immigration continues.

The various plans for exploiting colonial resources, the most complete being that put forward in the Chamber of Deputies by M. Albert Sarraut in 1921, have been inspired by a desire to lessen the dependence by France on foreign countries for raw materials. The French colonies are especially rich in minerals (phosphates, iron, coal). The production of phosphates in North Africa reached 2,600,000 tons in 1922; that of iron ore 1,800,000; Indo-China supplied Southern China with coal (900,000 tons); New Caledonia is the greatest producer of nickel after Canada, and her deposits of chrome are second only to those of Rhodesia. As regards agriculture, the production of cereals in Northern Africa in 1922 was 19,400,000 quintals of wheat, 19,200,000 quintals of barley; the production of wine was 10,900,000 hectolitres. There are 28,000,000 olive trees in Algeria and Tunisia alone; the exportation of fruits exceeded 300,000 quintals in 1922; that of early vegetables, 400,000 quintals. The live stock includes 17,650,000 sheep and 475,000 horses. French West Africa exported 153,000,000 fr. worth of ground nuts in 1922. Indo-China is the second exporting country in the world in rice—1,440,000 tons in 1922. The live stock comprises 4,000,000 oxen and buffaloes. The total area of colonial forests is 600,000,000 hectares, that is, about twice the total surface of France.

The private capital invested by France in colonial enterprises, exclusive of banks and railways, and of the milliards of francs spent by the state to pacify, organise and protect the colonies, exceeded 2,000 million fr. in 1924. The trade which France did with her colonies was 9,366 million fr. out of a total trade of 81,600 million francs. The public debt of the colonies is only three milliards. The colonies contribute a share to the central budget; in 1925 they paid 33,000,000 fr. as a contribution to military expenses, upkeep of the Ecole Coloniale, the Institute of Colonial Agriculture, the general agency of the colonies and the colonial air service. This share is very small, but shows the assistance which they can render France.

Such are the general characteristics of this colonial domain, the possession of which has had its effect on the traditional aspect of French policy. The French colonies have 15,086 km. of railways, 49,968 km. of roads, which are excellent in Northern Africa and Indo-China; and, although the Empire has not yet found its Kipling, French imagination has succumbed to that rosary of names, so exotically appealing to the tourists, Tunis, Algeria, Fez, Marrakesh, Damas, Angkor or Timgad, which envelop with a magnetic circle the central core of France. The French mercantile marine has found its true base in the colonies. The quickest routes between South America and Europe, will eventually lie across French Africa. This is mainly due to the railway between Algeria and Dakar, which has already been traced, and the air routes or motor roads already in use. French statesmen, thanks to this fact and also to the fact that many of them have already occupied high posts as governors in Africa or Asia, are gradually recovering the habit of thinking not merely nationally but geographically, and while the first place in their watchful eye is always the security of France, they have been led to play a practical part in world problems, where their predecessors confined themselves to theory.

VII. RAILWAYS

In 1911 the French railways consisted of five great private-owned and one state-owned line, with a combined mileage open to public traffic of 40,615 km. and a capital value of about 17 milliard francs. After the War acquisition of the Alsace-Lorraine lines, with mileage of 2,255 km., brought the total mileage up to 42,870 km., while owing to this increase and the large amount of reconstruction effected after the War on the Nord and Est lines, their total capital value rose to about 39 milliard francs.

In 1911 the French railways carried 511,000,000 passengers, in 1924, 776,000,000; the mean annual increase has risen from 3 % to 6 %. In 1911 184,000,000 tons were carried by goods train; in 1924, 265,000,000, an increase of 37 % in three years.

The commercial development of the railways was arrested by the War; not so their technical activity. Between 1914–8 they bore 41 % more traffic than in peace time—the lines near the front, 200 %. 15,400 trains were used during the period of mobilisation and concentration; between Sept. 1914 and Nov. 1918 about 100,000 troop trains carried some 6,000,000 men; besides returning empties, rations trains, munitions trains, leave trains, ambulances and a daily average of 200 trains carrying engineering material. Between March 21 and Nov. 11 1918, when traffic was densest, 50,000 military trains of all sorts were moved; counting returning empties, the traffic on the Nord system reached about 900 trains in 24 hours.

Most of this traffic fell on those parts of the Nord and Est lines not in enemy occupation; here important works had to be carried out during the campaigns. In Sept. 1914 bridges, etc., destroyed during the retreat from Belgium were reconstructed and lines and stations adapted to permit the extension of the Allied front to the Belgian coast, an operation which required 2,169 trains for the movement of troops alone. During the subsequent period of stationary warfare, single lines were doubled, railheads constructed, engineers and munitions dumps formed, whole new lines built; 13,500 km. of line were built, nearly 6,000 being behind the British front, and 28,000,000 cu. m. of embankment erected. These works, serving purely military purposes, were generally dismantled after the War.

The German Army in its retreat destroyed 2,047 km. of line (about half being double line), 600 stations, 1,100 bridges, 24 tunnels and all workshops and watering stations in its area. When these lines were reconstructed, the opportunity was seized to enlarge and improve the stations, lay the permanent way more rationally and introduce the latest electric, pneumatic or hydraulic points and signals. Especial attention was paid to the great goods yards in view of their importance for the reconstruction of the devastated areas. Lille-Délivrance station, for example, which dominates the goods traffic of Northern France, was constructed to clear 4,500 trucks daily. Its tracks are so arranged that it functions by the force of gravity, and requires only a small staff; it acts like a filter, all traffic, being passed in the same direction.

Locomotives and rolling-stock have increased in numbers and power, especially on the Nord and Est systems. There were 20,383 locomotives in 1924, compared with 13,434 in 1911; the load of the fastest passenger trains rose from 400 tons to 550 tons. Between 1920–4 the number of passenger carriages increased by 11 %, of goods trucks by 20 %; they are also much stronger and of increased capacity. The new all-steel one-piece carriages on the Nord line deserve especial mention. Examples of the carriages used on other lines were shown at the Exhibition of Modern Decorative Arts in 1925. Most goods trucks before the War carried a maximum load of 10 tons, few of over 20 tons. In 1925, of 525,000 goods trucks, 254,500 carried 10–20 tons; 227,000, 20–30 tons; 41,000, 30–40 tons; 2,500, 40 tons or over. The average carrying capacity of trains, especially on the main lines, has greatly increased. Many take 80 trucks, and 1,500 tons.

In the devastated areas, the railways were reconstructed earlier than the dwellings; so that the companies had to provide accommodation for their workmen on a large scale. The Nord built 11,141 houses of modern types, sometimes constructing regular towns, besides providing their employees with 6,300 other dwellings.

The problem of electrification only became urgent after the War when the altered economic conditions compelled France to utilise all her natural resources. A scheme was drawn up involving an expenditure of five milliard francs on the construction of power stations and the electrification of about 9,000 km., including 3,350 km., or nearly half, of the Paris-Orléans line; 2,300 km., or a quarter, of the P.L.M. line, and 3,200, or over three-quarters, of the Midi line.

An agreement between the state and the railway companies, made on June 28 1921, established a close financial and technical connection between the state lines of the Etat and Alsace-Lorraine and the group of the five great private companies. After satisfaction of the claims of shareholders and personnel, all proceeds are pooled; a deficit on one line is thus compensated by a surplus on another, the tariffs are fixed high enough to avoid a general deficit. Tariffs are uniform and common throughout France; rolling-stock is pooled; important purchases, as those of rails, sleepers, etc., are made in common; common are all arrangements regarding pay, promotion, employment, etc., of the 500,000 employees. All important questions of management are discussed in a committee composed of the Presidents and Directors of the seven lines; all matters affecting the employees or national interests are discussed in the Conseil Supérieur des Chemins de Fer, in which the above committee is reinforced by elected representatives of all grades of the personnel, the presidents of Chambers of Commerce and representatives of the principal national industries and of the state. The workings of this innovation have proved most satisfactory. See *Statistiques des Chemins de* *français* (annuel). (P. J.

FRANCHET D'ESPEREY, LOUIS (1856–), French soldi was born at Mostaganem in Algeria May 25 1856. Comm sioned to the infantry in 1876, he early saw active service Tunisia, Tongking and N. China. In 1908 he became gene of brigade, and the same year a tour of the Balkans and published studies thereon worked the beginning of an inter in that region which was to have important results. In 19 as general of division, he carried out a vigorous campaign Morocco, after which he was appointed to the I. Army Corps Lille. This corps he commanded during the battle of the Fr tiers, Aug. 1914, and on the eve of the battle of the Marne succeeded Gen. Lanrezac as commander of the V. Army. March 1916 he was advanced to command the eastern group armies, and later the northern group. On the recall of Gu laumat in June 1918, Franchet d'Esperey was sent out to repla him as Commander-in-chief at Salonika. Adopting and dev oping his predecessor's plan for an offensive in the Balka Franchet d'Esperey ensured the success of his break-through the skill with which he denuded the rest of the front to conce trate an overwhelming preponderence on the narrow Sok Dobropolye sector, west of the Vardar. Success beyond anti pation crowned the stroke; with their reserves pinned down vigorous pressure elsewhere the Bulgarians were unable to rep the breach, and as the Serbian spearhead drove in deeper, whole Bulgarian front collapsed, and on Sept. 29 Bulgaria c pitulated—the first defection among the Central Powers. If owed much to his predecessor, to Franchet d'Esperey was glory of execution and realisation. Exploiting this victory, cleared Serbia of the Austrian troops and later, on Jan. 5 19 took prisoner the German Marshal von Mackensen, in Hungar He afterwards commanded the Allied forces in Turkey un Nov. 1920 and was created a marshal of France on Feb. 21 19

FRANCIS FERDINAND (1863–1914), Archduke of Austri was born at Graz Dec. 18 1863. The eldest son of the Archduk Charles Louis and a nephew of the Emperor Francis Joseph, became, after the death of the Crown Prince Rudolph, the heir the Austro-Hungarian monarchy. In 1875 he took the title Archduke of Austria-Este, as heir to his uncle the Duke Modena, with whose death the male line of this branch of th house became extinct, and to his possessions in Austria-Hunga and Italy.

Until the death on Jan. 30 1889 of the Crown Prince Rudolp Francis Ferdinand was only known in limited circles and eve then he was not invited by the Emperor Francis Joseph to tak part in state affairs, although the Emperor frequently commis sioned him to represent him abroad. On July 1 1900 he marrie Countess Sophie Chotek (1868–1914), after having overcome, b tenacious persistence, the obstacle due to the fact that the la was not of royal family, and renounced a few days before th ceremony the succession rights of any children of the union. Thi renunciation was not only inscribed in the records of the imperia family, but ratified in the Austrian and Hungarian Parliament and sanctioned by a law of Dec. 4 1900.

After that time the Emperor gradually allotted to him respon sibilities of his own, not only in military matters but occasionally in questions of domestic politics. The difference of outlook o the two men, however, became more and more marked; for with advancing age Francis Joseph was less and less willing to consid far-reaching reforms, was anxious to avoid any conflict with the nationalities, and preferred advisers who knew how to untie a knot gently instead of hacking through it. Francis Ferdinan was convinced that the Magyar preponderance in the affairs o the dual monarchy must be broken in the interests of the monarchy and the dynasty. For some time he held that Federalism was the best solution. At another period he inclined to "Trial ism." Later, influenced by the Hungarian minister Kristoffy, he inclined to strengthen unity by changing the Delegations into a Central Parliament and attaching the annexed provinces Bosnia and Hercegovina, with a state organisation of their own, to the Empire. The opposition which he met on all sides from the ruling

y in Hungary strengthened his conviction that here lay the
ntial obstacle to the healthy recovery of the monarchy. In
severe conflicts between the Magyars and the Crown from the
nning of the 20th century onwards he, therefore, maintained
opinion that no concession must be made, and that there
ıld be no shrinking even from the use of armed force for the
nce of the rights of the monarchy and the dynasty.

he zeal with which he sought the solution of domestic politi-
problems by strengthening the central power is explained by
firm conviction that this was the indispensable condition of
monarchy as a Great Power, which he desired to maintain
to increase. Francis Ferdinand was not an unconditional
erent of the group which thought his aim would only be at-
ed by force of arms. But he was firmly determined to tread
path if it was the only one by which the goal could be reached.
considered that friendly relations with Great Britain were
rable, but towards France, and still more towards Italy, his
tude was cool and negative. He was convinced that there
st inevitably be a day of reckoning between the monarchy and
y. He never adopted an anti-Slav policy. He wished to
id conflicts with the principal representatives of the Slav
ionalities, and recognised in the Tsar of Russia the strongest
port against revolutionary movements in monarchical states.
the same time he expressed the decided opinion that the en-
achments of the Greater Serbia movement of Austro-Hun-
ian soil should be resisted with all the forces of the monarchy.
stood by Germany, yet was determined that the monarchy
uld not fall into dependence on her powerful ally.

rancis Ferdinand was a man of more than average ability.
would immediately recognise the essential point in any busi-
s in which he was engaged. What he lacked was knowledge
nen and calmness and constancy in his relations with the men
had been placed in high offices of state by his influence. He
ed from the citizens of the monarchy not affection, but sub-
sion to the will of the ruler. To him the state was identified
h the divinely appointed person of the monarch. He was shot
ıe 28 1914, with his wife, by Bosnians of Serbian nationality at
ajevo. (*See* EUROPE.)

Sturm. Erinnerungen an Erzherzog Franz Ferdinand (1925).

RANCIS JOSEPH I. (1830–1916), Emperor of Austria and
ng of Hungary (*see* 10.942).—In the last years of his reign
ncis Joseph continued to strive to preserve peace for his realm,
ile maintaining the prestige of Austria-Hungary and her
ition as a Great Power. Perceiving that this aim was threat-
ed by the confusion reigning in the Balkans, he agreed to the
n of his Foreign Minister, Aehrenthal, to take advantage of
Young Turk movement to annex the territories of Bosnia
l Hercegovina occupied in 1878, and to embody them per-
nently in the monarchy. During the serious crisis following
the annexation Francis Joseph backed Aehrenthal with the
ole weight of his influence, and subsequently supported him in
endeavours to restore friendly relations with the Great
wers which had been signally disturbed by the annexation,
l to put an end to the risk of international conflicts. By his
sonal intervention he in fact repeatedly succeeded during the
rs 1908 to 1914 in averting dangers threatening the peace of
rope. When in 1912 the Balkan wars, which he had untiringly
unsuccessfully striven to avert, began, he thought they were
gale before the hurricane, and when, in Aug. 1913, the Peace
Bucharest provided a provisional settlement he expressed the
nion that this peace was only the breathing space before a
sh war.

The behaviour of the Serbs filled him with the greatest
iety. When the murder of the heir to the throne, the Arch-
ke Francis Ferdinand (June 28 1914), led the Vienna Govt. to take energetic measures against Serbia, Francis Joseph hesitated to follow, and it was with a heavy heart that he gave his consent to the dispatch of the severe ultimatum to Serbia, and, after its rejection, to the declaration of war. He did not believe that the war could be localised, as he would have wished it to be, and was pessimistic about the chances of a world war. Even then he was of the opinion that "war is beyond our strength," and said he would be glad if the monarchy escaped "with a black eye." The attitude of the rulers of Italy and Rumania offended him deeply, and strengthened his doubt of a favourable outcome of a war against an ever-increasing number of adversaries. Francis Joseph stood immovably by the alliance with Germany, to whose ruler he was bound by a friendship based on reciprocal liking; it never occurred to him to separate from his ally. He would never have agreed to a separate peace; yet he favoured and supported every endeavour to put an end to the War by a peace which should safeguard the interests of all his allies and the position of Austria-Hungary as a Great Power.

In all questions affecting the constitution of the monarchy, and in particular the relations between Austria and Hungary, Francis Joseph continued in the later years of his reign to stand by the principles of the *Ausgleich* of 1867. He would not consider the federalisation of the Empire, but stood unmoved on the basis of dualism. He went a long way to meet the efforts of the Hungarian Govt. for independence, but refused energetically during this period demands tending towards the severing of the remaining bonds between the two halves of the monarchy, especially that of the united army. In the increasingly violent conflicts between the different nationalities inhabiting the Cis-Leithan territories Francis Joseph stood above party. This was all the easier for him on account of his indifference towards all the nationalities of his vast realm, even towards the Germans, although to the end of his life he felt himself to be a German prince. As in the earlier part of his reign, so in the last decade, the separate nationalities were favoured or neglected, but always played off one against the other. The meaning of *viribus unitis* for Francis Joseph was to use all in the interests of the dynasty.

But national consciousness had grown so strong that this policy had no success. The concessions which he granted in the years just before the War to the Slav peoples increased their self-confidence, and led them to make ever greater demands, the non-fulfilment of which caused a weakening of their sentiment for the dynasty. As the differences between the national parties represented in the Austrian Parliament became in the course of years so great that there was no prospect of effective co-operation, Francis Joseph ignored parliamentary activity from 1914 onwards. Experience of the World War led the old Emperor to recognise that he had done the Austrian-Germans an injustice; but isolated attempts to alter the trend of affairs had no lasting effect, and in the end he let things take their course. When he died, severe inroads had been made on the affection of the Austrian peoples; what remained was only just sufficient to disguise the disappearance of loyalty to the dynasty.

As years went on the Emperor became more and more lonely. His son had committed suicide in 1889, his wife had been murdered in 1898; of his brothers only the youngest was still alive, and he resided at a distance and in the strictest seclusion. There had never been any cordial relationship with the heir to the throne, Francis Ferdinand; and with the years, especially after Francis Ferdinand had married Countess Sophie Chotek, the estrangement between the two men increased, so that personal intercourse became rare. Among the remaining members of the Imperial House Francis Joseph only cared to frequent the circles of his two daughters, Gisela and Marie Valerie, and their children. He was bound by ties of true friendship to Katharina Schratt, formerly an actress at the Burgtheater, and in her society he spent his sparingly measured hours of recreation. The summer he usually spent at the watering place of Ischl, and there he devoted himself to the chase, the only pleasure for which he cared passionately to the end of his life.

The Emperor had long enjoyed excellent health. It was not until he had passed his 75th year that disease of the respiratory organs began. In 1911 this became so serious that a catastrophe was feared. All the preparations for Francis Ferdinand's accession were made. But the old Emperor recovered; and his physical as well as his mental energy improved from year to year, so that he was able in the first two years of the World War to transact fully all the business of government. It was only in the year 1916 that his faculties began to fail. He died peacefully of a fresh attack of his old malady on Nov. 21 1916.

Francis Joseph was not one of those of whom contemporaries, especially those at a distance, form any definite impression. The reserve which he observed even towards the great majority of his advisers made it more difficult to penetrate his real nature. He had a deep sense of his exalted position as a ruler. To the end of his days he remained profoundly convinced that the Empire over which he ruled was *his* empire, and the peoples *his* peoples. This conception of the majesty of the office bestowed on him by God found expression in his bearing. He always maintained a regal attitude. He showed kindliness and winning courtesy to everyone. Nothing was farther from him than posing, and no one ever heard him utter sonorous phrases; but he avoided any kind of intimacy even in his intercourse with members of the Imperial House, and, even with them, knew how to maintain his distance. His intellectual gifts were not remarkable, but he possessed sound common sense and wit. He had a strikingly good memory for persons and events. As a ruler he was a model of the sense of duty. From early morning to evening he attended to business with clocklike regularity, and dealt with all the documents laid before him with the greatest punctuality. This industry and his exact memory made him one of the best authorities in all Government affairs. He sometimes startled his ministers by his intimate knowledge of the details of the business in hand, and occasionally embarrassed them. But he went no further than details, and lacked the power of surveying the whole.

The Emperor also lacked, especially in his later years, the ability to take the initiative in important questions, to form independent resolutions and to carry them to their logical conclusions. In an ever-increasing degree he left the decision to his responsible ministers. He was not without skill in the choice of his advisers, but had an instinctive dislike for men whom he felt to be his intellectual superiors. He also disliked people of proud and upright character, and even within the family circle he preferred those who were more subservient. He was essentially cold in temperament, with great self-control increased by practice. Among the European rulers he enjoyed, during the last decades of his reign, great respect, which he owed to his age, experience, personal amiability, blameless conduct, and above all the fact that his word could always be relied upon. He was a faithful son of the Catholic Church, and looked up with reverence to the Holy Father; but, quite in the spirit of the traditions of his House, he guarded the rights of the dynasty and of the State with the utmost tenacity, even against the Pope. He took no interest in the arts and sciences, being in this respect more of a Lorrainer than a Habsburg; but whenever he expressed an opinion on these subjects, he showed a decided aversion from the modern tendencies. (A. F. Pr.)

Friedjung, "Kaiser Franz Josef I," *Historische Aufsätze*, p. 493 ff. (1919); Schneider, Kaiser Franz Josef und sein Hof (1921); A. A. V. Margutti, *Vom alten Kaiser* (1921) new edition (1925); Oswald Redlich, "Kaiser Franz Josef," *Neue Oesterreichische Biographie*, Band I, (1923).

FRANKFORT-ON-MAIN, GERMANY (*see* 11.17), has changed little outwardly since 1910, though the area of the city is now 33,277 ac., and the population according to the census of 1919 is 433,002. The life of the place still centres in the ancient and picturesque city, though in recent years blocks of old buildings round the cathedral have been swept away, and garden cities have arisen on the outskirts.

Frankfort is now an important inland port; heavy barges can navigate the Main as far as Aschaffenburg, and canalisation is being carried as far as Würzburg. The Rhine-Main-Danube canal is under construction, and a scheme has been prepared for a waterway to the Weser, which will link Frankfort with Bremen. Considering the difficulties of the process, the famous ban houses weathered the period of inflation well, and have lec way to the restoration of Germany's economic position in world. The metal, chemical and electrical industries of district are improving, and the old trade fair was revive 1919. In 1914 a university was founded, and in connection it is an academy of labour, designed to provide a new cla leaders for the labour movement. During the World War Fr fort was several times bombed, and it was occupied for a s time by the French in 1920 during the invasion of the Ruhr by German militarists.

FRASER, ALEXANDER CAMPBELL (1819–1914), Br philosopher (*see* 11.38), died at Edinburgh, Dec. 2 1914.

FRASER, CLAUD LOVAT (1890–1921), British artist and signer, was born in London, May 15 1890, and was educate Brighton and Charterhouse. He began to follow his fatl profession as a solicitor in 1908, but abandoned this three y later for art. After working with Walter Sickert for a tim exhibited in 1913, being responsible in the same year for decoration of the *Flying Fame* chapbooks and broadsheets served in France with the Durham Light Infantry during 191 but was gassed and invalided home. His gift for spirited de and lively colour, based to a great extent on 18th century ventions, developed rapidly, and he not only illustrated suc fully many books, but exercised a rejuvenating influence on lish stage designs by his production of *The Beggar's Opera* (1 *As You Like It* (1920) and *If* (1921). A career of great pro was cut short by his death, June 18 1921, at Sandgate, K See John Drinkwater and Albert Rutherston, *Claud L Fraser* (1923).

FRAZER, SIR JAMES GEORGE (1854–   ), British ant pologist, was born at Glasgow, Jan. 1 1854. Educated at Hel burgh, Glasgow University and Trinity College, Cambridge was elected a fellow of the latter college in 1879 and called to Bar in the same year. He was knighted in 1914, received O.M. in 1925 and became Commander of the Legion of Ho in 1926. A prolific writer, he is famous as the author of *Golden Bough*, first published in 1890 and re-issued in 12 volu under seven titles between 1907 and 1915. In 1922 appeare abridged edition under the original title. This work is an el rate study of ancient cults and folk lore and covers a vast of anthropological research. In 1926 he issued vol. 1 of *Worship of Nature*, dealing with the worship of the sky an the earth. Among his many other publications are: *Totem* (1887); *Adonis, Attis, Osiris, Studies in the History of Ori Religion* (1906, 2nd ed. 1907, 3rd ed. 1914); *Totemism Exogamy* (1910).

FREDERICK VIII. (1843–1912), king of Denmark (*see* 11. died at Hamburg May 14 1912.

FREEMASONRY (*see* 11.78).—The total membership has least doubled since 1910 and, according to the Masonic Book, Chicago, is (1926) about 3,922,318. In addition there at least 1,000,000 "unrecognised" masons, the most import group being the "Negro" masons of the United States America. Of the "regular" masons, all save 208,388 belong to various Grand Lodges of the U.S.A. and of the British Emp which indicates that freemasonry is essentially an Anglo-Sa institution.

Social Work.—In the U.S.A. and Holland the most notice change has been a tendency to take an active part in the so betterment of the nation. While avoiding controversial politi questions, the aim is to increase the interest of members in well-being of their fellow citizens outside the door of the lod This tendency is less marked in the British Grand Lodges, ow to their anxiety to avoid any appearance of interfering *as Mas* in politics, although in the field of charity they are particula active.

Anthropological School of Research.—Among British masons one the most notable changes has been the rise of a new school masonic research, which aims at tracing the history of Freemaso anterior to 1717. Faced by the paucity of documentary eviden due to the nature of the obligations taken by medieval masons, school has adopted the principles used in the study of anthropol and of comparative religions. It has discovered that figures carv or painted, by medieval masons, are often depicted making certain signs still known to Freemasons, and that in the scenes represented these clearly convey the same inner meaning as to-day.

Examples of such secret messages have been found in medieval and Comacine work and also in that done by members of the Roman Collegia. There also exists documentary evidence connecting these three groups of builders. A similar use of signs in Ancient Egypt, in the Hung Society of China and among savage races when initiating a boy into manhood, has also been demonstrated. On the basis of these facts, which are unquestionable, the theory is being developed that Speculative Freemasonry is descended via the Comacines, the Roman Collegia and the Mysteries from primitive rites, once universal in the dawn of history, survivals of which are to be found to this day in Central Africa and Australia. Concurrent with this work has been the careful study of the modern rituals, and the comparison of certain peculiar features in them with similar incidents in the ancient mysteries and in savage rites. The facts so far disclosed suggest that in modern freemasonry we may have an intellectualised survival of the cult of the Dying God and of the Fertility rites. Although this school has produced much interesting data, its conclusions are not yet universally accepted by the older or "documentary" school, the members of which consider that coincidence may explain the similarities to which their attention has been directed. If, however, the views of the Anthropological School are ultimately accepted, the result will be that the origin of freemasonry will be pushed back thousands of years.

The Mystical School.—Quite as important has been the rise of a distinctly spiritual school of thought, which endeavours to interpret the meaning of the ceremonies, and considers that in the rituals of the various degrees we have an allegory of the quest of the soul after mystic union with the Supreme Being. While often differing in detail, since they approach the subject from different angles, all the exponents of this school agree in the main principles, although in historical research they are often sharply divided, some belonging to the documentary school and others to the anthropological. Perhaps, however, the most important fact is the ever increasing interest among the rank and file in a subject which, even a few years ago, would have been treated with complete indifference.

Masonic Relations.—Since 1910 events have proved that the breach between Latin and Anglo-Saxon masonry was based on a fundamental divergence of opinion as to the basic principles on which the order rests, and this breach tends to grow wider year by year. The disastrous results of interfering in politics has been shown by the fact that the Italian and Hungarian Govts. have declared Freemasonry to be a danger to the State, and have suppressed it within their jurisdictions. In France opposition to the political activities of the Grand Orient culminated in 1914 in the formation of a new body, "Grande Loge Nationale Indépendante et Regulière pour la France," which avoids politics, and insists on belief in God. This body, which has increased rapidly in numbers, is recognised by the Grand Lodge of England. At the same time, one by one, most of the American Grand Lodges which were still in fraternal relations with the Grand Orient have felt compelled to sever relations.

United States.—Since 1920 freemasonry in the United States has grown with amazing rapidity, and in 1926 had a membership of nearly 4,000,000 men, organised in 50 grand lodges. While in many ways gratifying, the influx of new members raised many problems, to meet which two movements were started.

First, the National Masonic Research Society was organised in 1914, under the sanction of the Grand Lodge of Iowa, to encourage the education of Freemasons in the history, symbolism and philosophy of freemasonry. Its headquarters are in St. Louis, where its journal, *The Builder*, is edited. Second, the Masonic Service Assn. of the United States organised in 1919 more than 30 grand lodges—the first great co-operative movement in American freemasonry. It grew out of the service of the fraternity in the War, and had two objects, as stated in its constitution; firstly relief in time of nation-wide calamity, whether it be war, pestilence or other disaster; secondly education—the teaching of freemasonry as it has to do with the daily lives of citizens and the problems of the nation.

The educational programme of the association is based upon the doctrines of the fatherhood of God and the brotherhood of man, under five heads: religious liberty, equality before the law, equality of opportunity, the dignity of labour and charity. Its work is carried on by means of short talk bulletins read in the lodges of member jurisdictions, speaker's bulletins, lectures illustrated by films and moving pictures, books, and its journal *The Master Mason*, edited from its headquarters in Washington. The association is managed by an executive commission, composed of one member from each group of states into which the country is divided. As a result of these movements a better kind of masonic literature has been created, at once more accurate and more popular—a national masonic library of nine volumes, and a little masonic library of 20 volumes. The whole intent of the movement is to know more about freemasonry and to do more with freemasonry for the service of mankind.

Recent years have witnessed the building of great temples of freemasonry in many of the chief cities of the country, and also a remarkable growth of philanthropic activity—the building of homes for the aged and indigent, orphanages and hospitals and the organisation of the national masonic tubercular sanitoria association. Since the World War there have been tentative attempts to form an International Masonic Assn. but they have been largely abortive, so far as American freemasons are concerned, owing to the refusal of freemasons in the United States to affiliate with foreign bodies which remove the Bible from the lodge and do not require faith in a supreme being as a requisite of membership.

FRÉMIET, EMMANUEL (1824–1910), French sculptor (*see* 11.96), died Sept. 11 1910.

FRENCH, DANIEL CHESTER (1850–), American sculptor (*see* 11.98), numbers among his more notable recent works the four groups representing Europe, America, Asia and Africa for the New York Custom House; the Melvin Memorial at Concord, Mass. (1916); the 1st Division War Memorial, Washington, D.C. (1924), and the statue "Memory" (1911), which was purchased by Henry Walters and given to the Metropolitan Museum of Art. His statue of Abraham Lincoln, executed for the Lincoln Memorial, Washington, D.C. (1920), portraying Lincoln seated and in a meditative mood, occupies a superb though simple setting and is considered the crowning work of French's life.

FRENCH AFRICAN LITERATURE.—The enormous continent, of Africa on account of its geographical configuration, is apt to appear as a single unit. But this could only be if all negroes were of the same race; whereas, ethnically speaking, owing to the intermingling of blood and the differences of latitude and longitude, there are as many races of negroes as there are African tribes. An Englishman differs less from a Russian than an Ourlaf from a Haoussa, and a Haoussa from a Kaffir.

The outbreak of the World War brought home to France her need for man power, and she then began to turn her attention towards a race which sent her its men by thousands. In the midst of the madness and destruction that overwhelmed Europe, she realised that she had to do with men who were like children and whose virgin minds required cultivation. She was forced to recognise that, in spite of solid, imposing and well-documented volumes, the theories with regard to the natural superiority of the Aryan races, set forth by Count Gobineau in his *Essai sur l'inégalité des races humaines* (1853–5), had received an unpleasant shock. Moreover, the ideas which Dr. Cureau, a former Governor of French Equatorial Africa, and a follower of Gobineau, expressed in his learned and interesting *Sociétés primitives de l'Afrique equatoriale* (1912) have, after much discussion, been strongly attacked, first by Jean Finot, whose work *Le préjugé des races* (1905) has attained world circulation, and later by Doctor Huot, in "L'âme noire."[1]

The soul of the negro, as compared with that of the white man, is emotional, unstable, variable and incomprehensible. It cannot be fathomed either in the tales of the old navigators—they dealt too much in fable and fantasy—or in the journals of contemporary explorers. Those who have lived long enough with the negro have learned to hold him in affection, which, according to Stendhal, is nothing but the crystallisation of feelings and inclinations.

We cannot number among the initiated either Pierre Loti, impassioned admirer of the exotic—the poet and magician who was inclined to bewitch himself with his own incantations—or even Fromentin, whose *Un été dans le Sahara* (1874) and *Une année dans le Sahel* (1859) conjure up before us burning sand and blinding light; but we must include Isabelle Eberhardt, the *bonne nomade*, whose whole work is a glorification of Islam; and a group of other writers of whom the most outstanding are Robert Randau, whose novels *Les Colons* (1907), *Les Algérianistes* (1912) and *Cassard le Berbère* are powerful and vivid; F. Duchene with *Au pas lent des caravanes* (1922), *Thamil'la* (1923) and *Le roman du Meddah* (1924); Maximilienne Heller with *La mer rouge* (1923) and many others. These works, however, have been inspired less by the influence of Africa than by that of the Mediterranean. In spite of such works as *Terres de soleil et de sommeil* (1916) and *Le voyage du centurion* (1916) by Lucien Psichari, *Visions congolaises* by Louis de Raulin and *Les explorateurs* (1909) and *Le commandant et les Foulbé* (1910) by Robert Randau the true African influence has only prevailed since 1919.

Since that time there has been a harvest of such literature, including the remarkable *Visage de la Brousse* by Pierre Bonardi (1920) and *l'isolement* by Dominique Combatte, which exude the stifling atmosphere of a tropical forest. *Des inconnus chez moi* (1920), by Lucie Cousturier, is a work profoundly true, profoundly human as well as infinitely pathetic. *Batouala* by René Maran (1921), *La randonnée de Samba Diouf* (1922) by the brothers Tharaud, *Koffi* (1922) by Gaston Joseph, *Diato*, a mine of Mandingo folk-lore, by André Demaison (1923), *Métempsycose* by Madeleine de Valcombe (1923), *Pellobellé, gentilhomme soudanais*, by Oswald Durand, *Ulyse, cafre* (1924) by the brothers Marius-Ary Lebland, *Les Chansons de Kou-Singa* by Jean Marville have also contributed to the researches of such men as Delafosse, Bruel and missionaries of all classes, lay, military, commercial and religious. These works may not perhaps have the lyric character which runs through *A travers l'Afrique* (1910) by Captain Baratier, nor the humour of that caustic adventurer to whom Pierre Mille, the French Kipling, has given the name Barnavaux. They are, however, a valuable contribution to the study of the negro mind, and as such increase our knowledge of humanity. (R. MA.*)

FRENCH LITERATURE (*see* 11.110)—The 15 years between 1911 and 1925 were overshadowed historically by the events which preceded the War of 1914, by the War itself and by post-War preoccupations and difficulties. If the course of literature was not entirely determined by this concurrence of great events, it at least responded to them, and bears deep traces of their influence. These marks can be found in the writings of practically all those who were at work during this period. Two literary generations occupied these 15 years; one, the older, that of the writers who belonged to the preceding period, already famous or recognised in 1911, who were only continuing their work; the other, a younger generation, that of the writers who made their first appearance in 1914 or after 1918.

I. THE PRE-WAR GENERATION

The most important writers of 1911 and succeeding years have already been accounted for in the preceding period. It will suffice here then merely to recall their names and the books which they published after 1911. It will be more interesting to note the general tendency of literature at this point.

The peculiar characteristic of French literature in 1911 in the fact that the great movement of reaction against the cesses of naturalism which had started 20 years before reached its culmination, and with entire success. About 18 the doctrine of naturalism was still triumphant, and had i posed a general conception of things which was affirmed by t scientific spirit. It was material, subject to reason, in no w sentimental. It had invaded the novel with Zola, the theat and even made its way into philosophy. It claimed to make u of the discoveries of savants, of Berthelot in chemistry a Darwin in biology. It was fatalistic, pessimistic, setting its against religious beliefs and even against the tradition of t things of the spirit. It claimed to reduce all life, even the life the soul itself, to a mechanism of causes and effects, to a pure physiological basis.

It was about the year 1889 that new tendencies were ma fested simultaneously in poetry, in philosophy, in criticism a in the novel. While keeping as a fundamental principle t recognition of the fact, that is to say the method of observatio the newcomers insisted upon their observation being complet upon its taking into account the whole of reality, not mere facts, but also all the stuff of feeling, aspiration, of the impuls of the soul, of spiritual energy. As a result of all this, thoug became re-invigorated, took a new lease of life. Such was t accomplishment of men very different in their inspiration a their convictions. Paul Bourget and Barrès among the novelist Henri de Régnier among the poets, Rémy de Gourmont, Charl Maurras and André Gide among the critics, played a great pa in this change. Groups like those of the *Mercure de France*, t *Nouvelle Revue Française*, the *Cahiers de la Quinzaine*, under t leadership of Charles Péguy, did their capable share.

It may be said that in 1911 the distinction had been clearl made between science, which establishes laws and fundament causes and sets them forth in abstract terms, and art, whic manifests these causes sympathetically by appealing at one a the same time to the reason, the heart and the senses. Th works of a mathematician of genius, like Jules Henri Poincar had made for the development of a more exact conception science and the scientific method. The books of Henri Bergso especially the one which appeared in 1907 (*L'évolution créatric* had created a new spiritual awakening. Everything thus co tributed towards liberating the spirit from the narrow boun aries of naturalism. A literary outburst was the result, th main characteristic of which is that each work reflects the te perament and the tastes of the author, without dependence any school. Certain writers remain faithful to their concepti of the novel (Gustave Geffroy, *Cécile Pommier*, 1922), and th Académie Goncourt continue the tradition of objectivity an naturalism. But the brilliant group of psychological writer that followed Paul Bourget and Maurice Barrès goes back t Benjamin Constant and Stendhal, indeed even invokes Balzac and attempts to make of the novel a complete representation life, of the spiritual life as well as the social and material.

During the 15 years (1910–25) there appeared a brilliant serie of psychological studies. Writers already famous continue their work. Paul Bourget produced *Le Démon de Midi* (1914) *Némésis* (1918). Maurice Barrès wrote *Greco, ou Le secret d Tolède* (1912), *La colline inspirée* (1913), and just before hi death published that *Enquête aux pays du Levant* (1923), whic unites in itself all his peculiar qualities of thought and expressio and which remains one of his finest books. René Bazin (*Le nouveaux Oberlé*, 1919); Henry Bordeaux (*La maison*, 1913, and *La résurrection de la chair*, 1920); René Boylesve (*Tu n'es plus rien*, 1914, *Elise*, 1921); Louis Bertrand (*Jean Serbal*, 1924); Edouard Estaunié (*Les choses voient*, 1913, *L'ascension de M. Baslèvre*, 1920), attest the vitality of a *genre* which was trie with success also by Emile Clermont (1878–1915), author o *Laure* (1913); Louis Codet (1877–1918), author of *La petite Chiquette* (1911), *César Capéran* (1918), *La fortune de Bécot* (1919); and Roger Martin du Gard, of a more philosophical turn (*Jean Barois*, 1914, and *Les Thibault*, 1922).

The analytic and descriptive novel of manners continued with enri Lavedan, *Irène Olette, Le chemin du salut*, 1920–3); Abel ermant *Les Renards* (1912), *L'aube ardente* (1919), *La journée ève* (1920); with Gaston Chérau (*La prison de verre*, 1912, *monstre*, 1913). Jérôme and Jean Tharaud (*L'ombre de la oix*, 1917, and *Un royaume de Dieu*, 1920); Gilbert de Voisins *'enfant qui prit peur*, 1912); the tales of Henri Duvernois *e veau gras*, 1912, *Edgar*, 1912); Edmond Jaloux, Marcel oulenger, Eugène Montfort, Claude Anet, Charles Géniaux. n offshoot of the symbolist movement, the poetic novel of ntasy has its most illustrious exponents in the poet Henri de égnier (*La pêcheresse*, 1920, *Le divertissement provincial*, 1923); the poet Francis Jammes (*M. le Curé d'Ozeron*, 1918, *Le poète stique*, 1920); and in the young Alain Fournier (1886–1914), atched away too soon from letters by the War, whose book *grand Meaulnes* (1914) remains a charming and impressive ork. Finally, exotic literature, dominated by the great name Pierre Loti, finds brilliant expression in Claude Farrère *a Bataille*, 1911, *Dix-sept histoires de Marins*, 1914); Jérôme d Jean Tharaud (*La fête Arabe*, 1912); Pierre Mille, Marius-ry Leblond, and in the posthumous book of Louis Hémon on anada, *Maria Chapdelaine* (1916), which had a prodigious ccess.

---

[1] *Mercure de France* (Sept. 1921).

Women have always excelled in the literature of imagination. hree writers occupy the first rank in this respect—Colette, who s added to her already famous list of works *La vagabonde* 910), *L'entrave* (1914), *Chéri* (1920), *La maison de Claudine* 922) and *La fin de Chéri* (1926); Gérard d'Houville, daughter the great poet J. M. de Heredia, wife of Henri de Régnier, ho has a rare poetic gift and who tells in the most fluid style rose stories of charming and often profound imagination, *e séducteur*, 1914, *Jeune fille*, 1916, *Tant pis pour toi*, 1920), nd who has written in *L'enfant* (1926) a little masterpiece; and omtesse de Noailles, a poet of passionate and inspired quality well, who in 1923 under the title of *Les innocentes* published series of novelettes and meditations in which lyricism is made e vehicle of a daring frankness. Mme. Marcelle Tinayre pub-shed in 1920 *Perséphone* and in 1922 *Priscille Séverac*. Mme. ucie Delarue-Mardrus, a very gifted story-teller, observant nd poetic, wrote *L'âme aux trois visages* in 1919 and *Graine au nt* in 1925. Mme. Andrée Corthés received in 1920 the novel rize of the Académie française for her book entitled *Pour moi ule*.

At the theatre that most personal of writers, François de urel, produced *Terre inhumaine* (1923), *La viveuse* and *e moribond* (1925). G. de Porto-Riche pursued his vigourous udies of passion with *Le vieil homme* (1911) and *Le marchand 'Estampes* (1918). Maurice Donnay, so charming, and, at the me time, so melancholy and whimsical, has continued his social udies in *Les éclaireuses* (1913) and *La chasse à l'homme* (1920). lfred Capus, a lucid realist, ironical and with a gift for natural ialogue, produced *Hélène Ardouin* in 1913 and *L'institut de auté* in 1914. Henry Bataille (1872–1922), hypersensitive, ightly involved and exotic, brought out *Le Phalène* in 1914 and *'homme à la rose* in 1922. Henry Bernstein after a series of ramatic and violent plays (*L'assaut*, 1922), brought out *Le cret* (1917), in which his effects are drawn from psychology nd character. Comedy has owed its greatest successes to obert de Flers (*L'habit vert*, 1913, *M. Brotanneau*, 1914, *es nouveaux messieurs*, 1925); to Tristan Bernard (*Les etites curieuses*, 1920); to Francis de Croisset (*Le coeur dispose*, 912); and to Sacha Guitry, whose vivacity and wit find trium-hant expression in *Le veilleur de nuit* (1911), *L'illusionniste* 921) and *L'amour masqué* (1924). The most interesting tempts in the way of original work have been made by Fran-ois Porché, who in *Les butors et la Finette* (1918) and *Le Cheva-er de Colomb* (1922) combines in a curious way the relics of ncient traditions with an entirely modern feeling for symbolism; nd by P. Claudel, author of *L'otage* (1911), *L'annonce faite à arie* (1912), *Le père humilié* (1920) and *Le pain dur* (1918), orks sometimes obscure, but freighted with purpose of an in-ontestable quality, and with austere emotion.

In the domain of poetry all the squabbles of the schools had already been silenced by 1911. Symbolism had done its work. Its most illustrious representative, Henri de Régnier, had returned to traditional forms. Master of rhythm and of rhyme, connoisseur of language, sumptuous and self-contained, he has amplitude and richness. Cultured, a great reader of history and old books, he knows the past. He has at his command all the images supplied by legend, history, nature and art. The outcome of this is a magnificent and lordly poetry which is the mirror of the passions, the adventures, the glories and all the multiple forms of human destiny (*Poésies*, 1907, *Vestigia Flammae*, 1921). Much nearer symbolism, Francis Vielé-Griffin has studied the ancient myths and has attempted to interpret their eternal significance (*Voix d'Ionie*, 1914). Francis Jammes is the poet of nature and divinity. He knows the country well, and he speaks of it with a charming simplicity and freshness (*Les Géorgiques chrétiennes*, 1911–2). He shows the same ingenuousness, the same healthy realism, the same humility in his poetry of religious inspirations; he has in him something at once bucolic and Christian (*La Vierge et les sonnets*, 1919). Comtesse de Noailles is on the contrary pantheistic and pagan. Impetuous and consciously unrestrained, heavy with doom like a priestess of old time, she has sung in eloquent and remarkably rhythmical verse of youth, love, the beauty of the universe, and also of human unhappiness, implacable destiny and death (*Les vivants et les morts*, 1913, *Les forces éternelles*, 1920). In her last verses (*Poème de l'amour*, 1924) she has adopted a deliberately simple and bare style, in which is traceable a growing melancholy, a strange lassitude in her ardent work, and, by way of substitute for resignation, a courage full of serenity. Paul Claudel, a vigorous personality, penetrated by a faith which, unlike the tenderness of Francis Jammes, is austere and sometimes sombre, and has written poems (*La cantate à trois voix*, 1914, *Trois poèmes de guerre*, 1915, *La messe là-bas*, 1919), which present a mixture of rather obscure metaphysics, rather self-conscious simplicity, and vivid and powerful imagery.

Charles Péguy, ardent, sophisticated and simple, Socialist and patriot, has shown in his poems *Le mystère de la Charité de Jeanne d'Arc* (1910), *Le mystère des Saints Innocents* (1912), *Eve* (1914) a fluency which is slightly wearing because of his repetition of the same themes, but at the same time a real power due to sincerity, tenderness and the human need for faith and piety. Finally, Paul Valéry, who had made his appearance between 1889 and 1898 in reviews of poetry and letters, *La Conque* and *Le Centaure*, after having kept silence for a long while, published in 1917 *Le jeune Parque*, and in 1922 *Charmes*. These two extremely slender collections contained much substance under an unpretentious form, and established his reputation. Mathematician and philosopher, a subtle and experienced artist, a disciple of Mallarmé, to whom he owes much, he gives expression to an abstract and intellectual life which though slightly arid is still passionate, and his work has a deep full note. The tendency to return to simple, pure and classical sources is found also with Paul Fort, whose *Ballades françaises* are full of colour and imagination; with J. P. Toulet, Fernand Gregh, Abel Bonnard, Franc-Nohain, whose *Fables* (1921) are delightfully humorous; with Alfred Droin and Pierre Camo; while symbolistic description is the more natural vehicle for Jean Royère.

If one were obliged, in spite of this diversity of temperaments, to characterise the period between 1911 and 1914, one might make two observations. One is that in matters of form pre-War writers went back almost without exception to classical traditions, to proportion, simplicity, clearness. The other is, that as far as guiding principles went they were for the most part occupied with furnishing a moral discipline to their contemporaries, and that in the wake of dilettantism and naturalistic pessimism they laboured to restore notions of order, of decorum, of hierarchy, which to them seemed useful to the national life. Whatever may have been the glory of Anatole France, it was not he who was then a leader, and who exercised an influence over men's souls; it was Paul Bourget and Maurice Barrès. There appeared at the approach of that danger constituted by the War a phenomenon worthy of remark by historians of the future. The grandson of Renan, Ernest Psichari, wrote in 1913 *L'appel des armes*, and shortly afterwards *Le voyage du centurion* (1916). Political crises and intellectual visionings had brought about a state of uncertainty that might prove a cause of weakness. Under the pressure of national exigencies that were apparent to all thoughtful minds, French literature in 1911 was mainly inspired by the attempt, which has been justified by the facts, to assure the future of the threatened country, to make readers acquainted with the strenuous life and the fundamental principles of the social and moral worlds.

II. THE POST-WAR GENERATION

The War abruptly ended the literary careers of many young men, who were killed on the field of battle, men who in all branches of literary activity gave high promise—novelists like Alain Fournier and Emile Clermont, poets like Paul Drouot and J. M. Bernard, essayists like Dufresnoy and Pierre Gilbert. But with those who survived it and had passed through its fires it only stimulated the desire for expression. During the course of the War there appeared a series of brilliant books of diverse character, but sincere and passionate, retracing the heroic years. It is impossible to mention all, but we must at least set down here *Le songe* (1922), by Henry de Montherlant; *Les croix de bois* (1919), by Roland Dorgelès; *Le feu* (1916), by Henri Barbusse; *La flamme au poing* (1917), by H. Malherbe; *Gaspard* (1916), by René Benjamin; *Civilisation* (1918) and *La vie des martyrs* (1917), by Georges Duhamel; *Sous Verdun* (1916), by Maurice Genevoix; *La guerre à vingt ans* (1924), by Philippe Barrès; *Fond de Cantine* (1920), by Pierre Drieu la Rochelle, and *Les récits de guerre dits à une femme*, by Camille Mayran. None of these books pretends to give a summary or to describe the whole of the War. It will be a long time before these great events will find their poet to synthesise and express them; Bonaparte had to wait for Victor Hugo. But all these works powerfully represent direct impressions and strong emotions; they have a meaning, and our grandchildren will find in them one day a sincerely moving record of a period that was shaken by a terrible storm.

This interesting and noble outburst necessarily faded as the events moved further away. The current of life which had been interrupted for four years took up its course again. All countries had to repair the consequences of the conflict. New problems arose. Difficulties mounted. The combined effect of all these causes was that there was no longer a collective effort. Everyone returned to his own preoccupations, to the world of his own imagination and fancy. More or less indifferent to the heritage of their elders, the young writers appeared to be under the impression of existing in a new world where they had to recreate everything. But nevertheless they remained under the influence of the past, sometimes without suspecting it themselves. They discovered, by the very fact that they lived in a predetermined epoch, the result of the labours of their elders. Tendencies, varieties of talent and aspirations are very diverse. There is little unity in the literature of the younger generation. Everyone follows the inclinations of his own temperament. The situation viewed as a whole gives the impression of a melting pot in which everything is in a state of fusion but out of which one day something new and unforeseen will spring. Let us try, in so far as we can to-day, to discern what this may be.

The dominating form in modern literature is always the novel, and it will serve as a type. It is not distinctively, in spite of the definition, a narrative representing life, but often consists of recollections like a book of memoirs or of reflections like a book of essays. The strongest influence to appear has been that of Marcel Proust (1873–1923). According to the date of his birth he belongs to the pre-War generation; but one finds that his work appeared almost entirely during or since the War. Only the first volume of his great novel *A la recherche du temps perdu*, namely *Du côté de Chez Swann*, had appeared by the end of the year 1913. All the others appeared in sequence down to 1925. Marcel Proust is remarkable for the depth and daring
of his analysis. Gifted with an acute, morbid sensitivity,
probed deeply into the motives of the heart and soul. W
an extraordinary delicacy and detail, he succeeded in expr
ing new and original nuances of thought in sinuous and o
interminable sentences. The bold analysis of the emotion
French literature had begun some years before Marcel Pro
by Anatole France but with discretion, and later with m
freedom by the female writers; but Marcel Proust has g
much further. He has carried the taste and feeling for in
spection to the extreme limits. By this one can say he
enlarged the scope of the novel, and that is the reason for
great prestige and influence among post-War writers.

This preoccupation with analysis is found in a series of w
the most characteristic of which are: Jacques Rivière's *A*
(1921), Jacques de Lacretelle's *Silbermann* (1922) and
Bonifas (1925), and Drieu la Rochelle's *Etat civil* (1921).

Chabaneix). The novelists do the same; M. Pierre Benoît
master of the novel of adventure; he knows how to const
he knows how to tell a story; and addressing himself to a p
which, as after every period of upheaval, is in need of dis
tion, he has been able to captivate the attention in a seri
well-made novels (*Koenigsmark*, 1918; *L'Atlantide*, 1919;
de la Ferté, 1923; *Le puits de Jacob*, 1924)—in which he sho
remarkable facility in employing imaginary or historical e
and in keeping the reader breathless with suspense over
turns of his stories.

It is only necessary to recall *Le kilomètre 83*, by Henry
guerches (1913), to show that since before the War the tas
the novel of adventure had been revived. The influen
Anglo-Saxon literature, and particularly that of Kipling,
been a powerful stimulant in this development. The
naturally only accentuated this tendency. A proof of th

nd in the books of Pierre MacOrlan (*La cavalière Elsa*, 1921), Louis Chadourne (*Terre de Chanaan*, 1921) of Jean d'Esmé *s Barbères*, 1925), of Roland Dorgelès (*Le reveil des morts*, 3), of René Bizet (*La sirène hurle*, 1921) and of J. Kessil *Steppe rouge*, 1922, *L'Equipage*, 1924). All of these appeared ween 1918 and 1925. Actually, however, it does not seem t this form of literature is capable of much further develop- nt, except in the case of the exotic, historical or colonial el. French literature is traditionally psychological. It is racteristic that the best book of Pierre Benoît, the most ular writer of novels of adventure, is a novel of manners, *v. de la Ferté* (1923).

rancis Careo is a painter of the lower depths of society, of world of the apaches and of the outer boulevards. He deals, did Francois Villon in his day, with the world of thieves. Has handled this difficult subject with a great deal of tact *s innocents*, 1916, *L'homme traqué*, 1922, *Perversités*). Francis rco is a true artist with a quick sensitivity. He has made a dy of those who take no count of laws nor of social conven- ns; he has caught human beings with all their passions and their energies. He has shown how they live beyond the law l current morality; how they have made their own laws, ated their own code of honour and conventions. There are his work many amusing, picturesque and curious scenes, but re is more. He has analysed, often with profound sympathy, se creatures of an outcast world and their imagination, ams and miseries.

ean Giraudoux is also a subtle analyst. He has a capricious agination and a very individual, if somewhat complicated, tic manner, which makes him difficult reading; but he is pro- cative. There is in him much humour, often of an unexpected d, difficult to understand. The world of images has no secrets m him. Unusual comparisons and strange associations of as abound in his books. The most successful of these is *anne et le Pacifique* (1921), the story of a shipwrecked young l who lives alone on a desert island. She has to reorganise her , and by a series of chances and deductions she discovers that War, of which she knew nothing when she left, is going on. ychology in this book takes precedence over adventure, for author primarily wished to portray the reactions of an iso- ed human being in face of the vast world.

Henry de Montherlant is one of the most gifted among the ung writers. He has a sense of style, and is capable of vigorous ntal activity. After *Le Songe* (1922) he wrote about Verdun, d about sports (*Les onze devant la porte dorée*, 1924), books ich disclose his national and moral preoccupations. He is erested in the disciplines which make a human being master himself, permit him to live under the best conditions, and e the greatest possible value to his acts. He is very modern, d at the same time deeply attached to tradition; his works filled with youthful ardour, strength of will, and an impetu- ty which express themselves in vivid and poetic language.

François Mauriac is a harsh and powerful novelist. His books *e baiser au lépreux*, 1922, *Genitrix*, 1923, *Le désert de l'amour*, 25) have placed him among the most notable writers of his neration. Brought up in the Catholic tradition and attached his faith, François Mauriac is aware both of the demands posed by a Christian life and of the weaknesses of most man beings. All his work, which incidentally is open-minded, ems dominated by the idea of sin, by the necessary artifices in ich egotism and passion entangle human beings, by the thingness of their desires and the need for discipline. He mbines realism, austerity and even daring. Just as in cathe- als, where bold sculpture representing vice and demoniac in- irations are adjacent to sacred architectural motives, so he s put into his work scenes that are sordid enough, side by side th aspirations towards purity.

André Maurois, who during the War was interpreter with the itish Army, made his début with an impressionistic book, titled *Les silences du Colonel Bramble* (1918), which had a eat success. He published in 1923 *Ariel, ou la vie de Shelley*, ich had great charm, and *Des dialogues sur le Commandement* (1924). He is less a novelist than an essayist. He has a penetrating, highly cultivated mind and loves the play of ideas; he excels in delicate analyses, in the nuances of the emotions and in psychological insight.

Valéry Larbaud is interested in the manifestations of the international mind, and has written fascinating novels. *Fermina Marquez* is an original study of the life of young people in South American schools. *Le journal d'A.O. Barnabooth*, which followed, is a novel in which satire is mingled with poetic fancy. In it he amuses himself with drawing the life of a millionaire who can see everything, buy everything, and almost do what he pleases, and yet is stifled with boredom and doubt, finding pleasure only in doing everything that runs counter to the conventions of his social position. This story of the weariness of one of the inheritors of the earth is written with a vivacity which is one of the most curious characteristics of modern art.

Paul Morand represents the impressionist school at its acme of success. His short stories *Ouvert la nuit* (1922), and his novel *Lewis et Irène* (1924) are certainly among the most entertaining studies of the present time. Paul Morand has a keen feeling for the feverishness and instability of contemporary life. He is also keenly aware of the international aspect of post-War cities—the mingling in all countries in the same places, restaurants and hotels of people belonging to every race and nation. He has caught finally the elementary flashes which these cosmopolitans have in common by way of certain instincts and manifestations. His pictures are alive and chaotic. The author contents himself with incisive characterisations and brief formulas. He is full of verbal coinages. He reduces the recital to the bare essential. There is something acrobatic and artificial in this art, but the feat is always successful and entertaining.

A great number of other writers and books should be added to this summary. There is much diversity of literary activity. Works like *Les métiers blessés* (1919), by Pierre Hamp, and *Les entretiens dans le tumulte* (1919) and *La confession de minuit* (1920), by G. Duhamel, are a combination of social study and meditation; others, like those of Jean Rostand (*De la Vanité*), revive the tradition of the writers of maxims and of the moralists; others, like those of Alexandre Arnoux (*La nuit de Saint Barnabé*), constitute in the form of a narrative an interesting attempt to represent material civilisation and to give a picture of the modern industrial and mechanical world.

The attempts at a revival of the theatre, undertaken by the "Théâtre du Vieux Colombier," are continued chiefly by the "Atelier." While plays with Deval and Natanson were rather psychological, with Zimmer rather sombre, with Marcel Achard rather fantastic, with Géraldy rather sentimental, the modern play is sketchy, containing little action, and above all else designed to portray character. So it at least appears among the last comers, J. J. Bernard, Obey, Amiel, Steve Passeur. The construction is loose, without complications. The young dramatic authors seem to desire chiefly directness; they have no ambition to uphold theses, and wish only to amuse and to provoke reflection.

This article does not pretend to give a complete survey of present-day literature. It is being made, and there is no history at present. All that is possible is to indicate general characteristics; the appearance of men of talent may change everything to-morrow; the appearance of a genius may accentuate current tendencies or transform them. If one wished to summarise the various comments which have been made, one might say that literature in 1926 is still dominated by pre-War writers After the activity which showed itself in the years 1918–20, it seems there should have been a sort of fruition. Many talents with a certain ingenuity have been revealed, many young writers with distinctive personal qualities have published their books. But no single work dominates recent years or seems capable of exercising a determining influence.

It is then towards the masters of yesterday, who are still living to-day (except Barrès and Marcel Proust) and who are still exercising their influence, that little by little the younger men are turning their attention. The names of Paul Bourget, Maurice Barrès and Henri de Régnier, and those of Colette, Marcel Proust and Charles Maurras are dominating our period. Even when they know them only slightly or when they try to free themselves from them, the newcomers live in a society the ideas of which have in some way been fashioned by their elders. They breathe in air which is that of their time. One notices that the psychological analysis of Marcel Proust has strongly influenced some, that the impressionistic realism of Colette has attracted others, while the disciplines formulated by Bourget and Barrès form the mainstay of a great number. It is significant that a young writer like Drieu la Rochelle should leave his particular set and return to the Barrès tradition, and that after years of charming unconformity Jean Cocteau should entitle a book of essays, *Rappel à l'ordre.*

Thus after a detour of 10 years, violently disturbed by the War and its aftermaths, one can say that in 1925 French literature again took up the road which was foreshadowed in 1914. All the schools, after their trials and struggles, have achieved their work and have transmitted the best that was in them. The quarrels between romanticism and naturalism, between the Parnassians and the Symbolists have come to an end. The opposition between scientific rationalism and the world of the spirit has become less acute. It was a long struggle, bearing witness to the vitality of literature; of all the doctrines nothing is left but the trace of whatever in them was useful and true. Present-day French literature seems to be going in the direction of a classic revival in which certain other elements are mingled.

FREUD, SIGMUND (1856–), Austrian physician and psychoanalyst, was born on May 6 1856, at Freiburg in Moravia, and studied medicine and psychology at Vienna, being strongly influenced by Brücke in the latter subject. After working in Paris under Charcot from 1885–6, he devoted himself, in co-operation with the Viennese physician, Josef Breuer, to the study of nerve cases. The results of their joint investigations were published in 1895 as *Studien über Hysterie*, expounding a new treatment, the so-called *catharsis.* This consisted in putting the patient in a hypnotic state, and the examination by the physician, while under this condition, of the forgotten original circumstances under which the symptoms first appeared. Subsequently Freud pursued a path of his own, and developed a special technique (*see* PSYCHO ANALYSIS). The technique and the results of this research work are explained in Freud's most important works: *Die Traumdeutung*, 6th ed. (1921); *Zur Psychopathologie des Alltagslebens*, 7th ed. (1920); *Drei Abhandlungen zur Sexualtheorie*, 4th ed. (1920). Freud's shorter works were collected in four volumes under the title, *Kleinere Beiträge zur Neurosenlehre.*

Freud also published two general sketches of his theory: a shorter one, *Fünf Vorlesungen über Psychoanalyse* (delivered at Worcester, Mass., in 1909) and a comprehensive one in *Vorlesungen zur Einführung in die Psychoanalyse* (1917). These medical-psychological studies yielded surprising results in relation to other subjects, and in the possibilities of their adaptation in other branches of knowledge, *e.g.*, mythology and the history of religion, civilisation and literature. The principal works in this connection are *Totem und Tabu*, 2nd ed. (1920); *Der Witz*, 3rd ed. (1921); *Eine Kindheitserinnerung: Leonardo da Vinci* (1916); *Jenseits des Lustprinzips* (1920); *Massenpsychologie und Ichanalyse* (1921). Freud's works have been translated into English.

FRIEDJUNG, HEINRICH (1851–1920), Austrian historian,
born at Roštìn, Moravia, Jan. 18 1851 of Jewish parents. Fri
jung spent much of his career in political journalism; he wa
pronounced German nationalist, and the chief author of
nationalist *Unser Programme* of 1885. At the same time
devoted himself to historical research, especially over the per
1848–66, which he covered brilliantly and exhaustively
the three works *Oesterreich von 1849–60* (1908–12); *Der K*
krieg und die oesterreichische Politik (1907); and *Der Kampf*
die Vorherrschaft in Deutschland, 10th ed. (1917). His o
chief works are the volume *Historische Aufsätze* (1919) and
monumental review of modern times *Das Zeitalter des Imper*
ismus (1919–22), which was finished by Professor A. F. Přibr
after Friedjung's death in 1920.

Friedjung was a conscientious and an attractive histori
whose works cover all aspects of life during the period w
which they deal. The point of view expressed in them is, ho
ever, pronouncedly liberal, patriotic and anti-Catholic, a
shows little sympathy for the Slav and Magyar nationa
movements in the Dual Monarchy. His last excursion into p
itics was most unlucky, and undeservedly clouded his name;
March 24 1909 when the conflict between Austria-Hungary a
Serbia over the annexation of Bosnia-Herzegovina was at
height, he published an article in the *Neue Freie Presse*, accusi
the Serbo-Croat politicians in the Monarchy of treasonable pr
tices with the Government of Serbia, and violently attacki
conditions in Serbia. Fifty-two deputies of the Croato-Se
coalition and their leader Supilo separately, sued Friedjung
libel. It was disclosed that Friedjung had received the doc
ments on which his article was based from the Austro-Hungari
Foreign Office, that he had accepted them in good faith
after most insufficient scrutiny and that some at least w
blatant forgeries. The affair ended at last in a compromise,
not until it had assumed the proportions of a European *ca*
célèbre. Friedjung died in Vienna July 14 1920.

See Dr. R. W. Seton-Watson, *The Southern Slav Question and*
Habsburg Monarchy (London, 1911).

FRIEDRICH, JOHANN (1836–1917), German theologian
11.216), died in Munich, Aug. 19 1917.

FROHMAN, CHARLES (1860–1915), American theatri
manager, was born at Sandusky, O., June 17 1860. At the a
of 12 he started to work at night in the office of *The New Y*

ibune, attending school by day. In 1874 he began work for *e Daily Graphic*. In 1877 he entered the theatrical business, ng for a time associated with his brother Daniel in managing Madison Square Theatre, New York. In 1890 he organised Charles Frohman Stock Company. On Jan. 25 1893 he ened his Empire Theatre, New York. Other New York thea- s with which he was at various times connected were the terion, Garrick, Knickerbocker, Lyceum and Savoy. He was adept in developing talent. Among his successful players re Maude Adams, Ethel Barrymore, Blanche Bates, Billie rke, William Gillette and Otis Skinner. During 1905–6 presented E. H. Sothern and Julia Marlowe in Shakespearean ys. He was one of the organisers of the syndicate which for eral years controlled the American theatres. Beginning in 97 he presented many plays in London, leasing at different nes such houses as the Duke of York's, Globe, Comedy, Vaudele and Adelphi. He perished when the "Lusitania" was sunk a German submarine May 7 1915.

FRONTIERS, BATTLES OF THE.—The generic name of " bat- s of the frontiers " covers the whole of the actions fought at e opening of the World War in Aug. 1914, on or near the French ntiers. For convenience these are here divided into six sec- ns, each of which deals with a more or less distinct part of the ies of operations. These are: I. Early operations in Upper sace; II. First battles in Lorraine; III. Battle of the Ardennes; . Charleroi and Mons; V. Le Cateau; and VI. Guise.

I. EARLY OPERATIONS IN UPPER ALSACE

At the beginning of the World War the French higher com- nd was governed by two ideas. One was to avoid posing as the gressors, and consequently the covering troops were with- awn 10 km. behind the frontier. The other idea was to plant e flag in the lost provinces as quickly as possible. Not only, erefore, were strategy and politics not in harmony, but politics ntained a double element, the one pacific, the other aggressive.

First French Advance.—Immediately on the order for mobilisa- n, an advance on Mulhouse was ordered. The offensive began the morning of Aug. 7. Its start was promising. Mulhouse is reached and occupied in the evening of the 8th. The news the approach of large German forces then became known. e French commander feared being caught in a trap, and after eight-hour occupation the town was evacuated, a position rear being occupied. During the evening of Aug. 9, the Ger- ns attacked with superior force and drove back the French. e success was not followed up, since German supreme head- arters had prepared for a massed attack on Luxembourg and lgium, which postulated a strict defensive in the south.

The retreat from Mulhouse was likely to have a prejudicial ect upon the French. To counteract it Joffre formed a special my of Alsace. Early on Aug. 19 the Germans in front of Mul- use were attacked and defeated, and at 4 P.M., for the second ne in a fortnight, the victorious French entered the town. t though fortune seemed here for the moment to smile upon e French, reverses elsewhere extended their influence to Alsace. ders were issued for the break-up of the Army of Alsace and e dispersion of its units. Mulhouse was again evacuated on ig. 25. The fortress of Belfort was thus exposed and open to stile attack.

Belfort and Dannemarie.—Belfort had two rôles to play, the e permanent and foreseen, the other thrust upon it very early the War. In the first place, the fortress was designed to close e gap existing between the Vosges and the Jura. It was a tally important rôle, for if the Germans secured the gap they ight penetrate into the heart of France. The other rôle was to rm a pivot for the bending back of the whole French line, from e Swiss frontier to Belgium. A vast amount of work had been ne during the preceding 40 years to convert the small fortress 1870 into the immense stronghold of 1914. Much, however, mained to be completed. The completion of the task was nec- sarily impeded by the fighting in which part of the garrison is engaged during August. Nevertheless, by the time that the my of Alsace was broken up the enormous undertaking was achieved. The armament of the forts had been completed; numerous batteries had been constructed and armed; centres of resistance had been organised; and inundations in front had strengthened the zone of defence.

On the other hand, the German heavy artillery had introduced a new factor into war. The crushing of the resistance of Liége and Namur was disconcerting. By Aug. 25 there could be no possible doubt that if the Germans were allowed to plant their guns 8 km. from the forts the heart of the place would be bombarded and the forts themselves smashed before the artillery of the defence could fire a shot. Furthermore, by Aug. 25 the Allies were withdrawing all along the line. Clearly the Germans might make a special effort to seize the pivot on which this withdrawal hinged.

In these circumstances, and knowing that he had only his own resources to count upon, Gen. Thévenet, Governor of Belfort, decided not to await the enemy's attack, but at once to assume the offensive. The plan was quickly put into operation. The offensive reconnaissances in front of the fortress began on Aug. 28, and from that date were pursued without interruption. So successful was the operation that by Sept. 10 the advanced guards were over the frontier and 11 m. from the fortress. Eight days later the headquarters of the 57th Div., whose daily reconnaissances had been carried on uninterruptedly in advance of its front, was transferred from Foussemagne to Dannemarie. This transfer made a great impression in France, as also in Alsace, and had all the importance of a victory. It was indeed a considerable success, for the occupation of Dannemarie had been carried out with such precision and solidity that it had now to become definite. From Sept. 18 1914 onward, the French flag never ceased to fly over the little Alsatian town thus reconquered.

II. FIRST BATTLES IN LORRAINE

The first French plan (General Instructions No. 1 of Aug. 8 1914) was purely offensive. It proposed to seek action with all forces united with the right on the Rhine. The two armies of Lorraine (I. and II.) were to lead, the I. in the direction of Saarburg, after having thrown back the German VII. Army towards Strasbourg and lower Alsace, while an isolated corps, the VII., would make a diversion to the east of the Vosges. The II. Army, covering itself from Metz, was to attack in the direction of Saarbrück, pivoting on the I. in the neighbourhood of Étangs. The two left corps were situated to the west of the Moselle, with a view to their eventual employment in the north.

Disposition of Forces.—In front of the I. and II. Armies the Germans had approximately equal strength (VI. and VII. Armies). They would at first keep to the defensive, acting as a pivot to the huge wheel being made by their centre and right. The rapidity of the invasion of Belgium determined the French to hasten the operations in the east in order to make a diversion. On Aug. 13, the I. Army had two corps on the Meurthe (VIII. and XIII.). Gen. Dubail, commanding the I. army, counted besides on the co-operation of the two right corps of the II. Army and on that of the XXI. Corps descending from the Vosges on his right. On Aug. 16 the II. Cavalry Corps was placed under his orders. The final concentration of the complete fighting force, however, could not be complete until the 18th. Nevertheless, the XIII. and VIII. Corps moved on the 14th, and on the 15th entered Cirey and Blamont, pushing back the I. Bavarian Corps, which retired toward Saarburg.

By the evening of the 17th the two French corps had reached the line Vasperveiller-Aspach-St. Georges, and the XXI. extended the line toward the Vosges. The II. Cavalry Corps had orders to go ahead on the 18th towards Saarburg, which was entered after a skirmish. The XXI. Corps pushed to the northeast as far as Walscheid; the XIII. held the heights north and east of Saarburg; the VIII., marching on Heming, seized the passage of the Marne-Rhine Canal and entered Saarburg. The II. Cavalry Corps bivouacked toward Diane-Capelle, in liaison with the II. Army, which had reached the line Bisping-Château Salins. The Germans held entrenched positions on a front of 40 m., from the neighbourhood of Dobbenheim to Biberkirch.

French Offensives.—It was decided that the I. Army should attack with its left northwest of Saarburg, its centre and right standing fast to repulse an eventual counter-attack in the Vosges. The II. Cavalry Corps was to move on Saar-Union in order to operate south of the Saar. On Aug. 19 the VIII. Corps commenced the attack before dawn, gained the terrain northwest of Saarburg and repulsed a counter-attack. On the 20th it resumed the offensive, but during the morning it became evident that it was incapable of opening a passage for the Cavalry Corps; indeed it was necessary to bring back a division on the canal with heavy losses. In the centre and on the right the French were more fortunate. The XXI. Corps met no resistance on the 19th, and the XIII. had not yet been engaged.

On Aug. 20, the XXI. Corps, attacked by the German XIV. Corps, inflicted on it a serious check near Walscheid; the XIII. Corps, coming into line, attacked to the northeast of Saarburg, disengaging the right of the VIII. Corps, which held the town till nightfall. Dubail's intention was to entrench on the front Kerprich-Soldatenkopf, and to undertake afterwards a methodical advance; but the check to the II. Army led Joffre to direct a retreat in Lorraine. On the morning of Aug. 21 the I. Army retired slowly towards Blamont. Afterwards it was necessary to accelerate the movement on account of the rapidity of the retreat of the II. Army. On the evening of the 23rd, the I. Army extended from Dames-aux-Bois to the Col du Bonhomme. It had suffered heavy losses, the casualties in the VIII. Corps amounting to more than 50 per cent.

The offensive of the II. Army (de Castelnau) had been still less fortunate. On Aug. 14 the XVI. and XV. Corps moved in the direction of Avricourt, with the bulk of the XX., the remainder covering the front to the north. In the evening, it faced to the northeast on the high ground at Gondrexon, the XV. Corps alone having been stopped by the enemy at Moncourt. On the 15th the advance was still checked by the condition of the XV. Corps, which had suffered heavily; the XVI. Corps reached Igney-Avricourt, the XX. Bezauge-la-Petite and Xanrey. The IX. Corps remained on the Grande Couronne east of Nancy and sent out detachments toward the northeast.

On Aug. 16 the Germans continued their retreat and the French followed rapidly as far as Morhange, northwest of Donnelay. On the 17th the army was to swing round to the northwest toward Delme-Chateau Salins-Dieuze. The XVI. Corps progressed without difficulty; the XV. occupied Marsal, but could not bring its main body beyond the Seille; the XX. Corps, in possession of Château Salins, reconnoitred toward the north. Rearguard fights only were expected, but on the 18th the XVI. Corps from the early morning met the enemy in strength. The German artillery held the XV. Corps in the valley of the Seille and prevented it from occupying Dieuze. The XVI. Corps had to fall back on Angviller, and only the XX. advanced to the north of Morville-les-Vic and Château Salins. In spite of the loss of the IX. Corps, sent to the IV. Army on Aug. 18, de Castelnau ordered for the 19th the continuation of the offensive in the direction of Loudrefing, Bensdorf and Morhange.

French Retreat: Aug. 19–20.—From the morning of Aug. 19 the XVI. Corps was stopped on the Salines canal; the XV. could not pass Zommange and Vergaville; and only the XX. could make a real advance, pushing a brigade as far as Morhange. The 68th Res. Div., which had relieved the IX. Corps, insufficiently covered the left of the XX. Corps. De Castelnau ordered for Aug. 20 a combined attack by the two other corps on the line Cutting-Dommon-Bassing; the XX. was to consolidate its positions, ready to march to the north or northeast. On the 20th the corps on the right, instead of progressing, was attacked and even thrown back. The XX. having attacked and not having improved its positions was stopped by de Castelnau, but the Germans, taking the offensive, threw the left back on Château Salins. The right followed this movement on Lidrequin and the 68th Div. resumed its position of the previous day. At 4 P.M. the general ordered a retirement, which began during the night and co tinued through Aug. 21 under the protection of the XX. Cor and the 68th Division. In spite of the arrival of two new reser divisions and the II. Cavalry Corps, the II. Army had to ret to the west of the Meurthe, the left to St. Nicholas. To the nort three divisions held the Grande Couronne.

French I. Army Action.—On Aug. 23, the I. Army commenc a three weeks' battle destined to stop the enemy and support t strongly attacked II. Army. To effect this, it took the offensi on the 24th and 25th, while the II. Army threw back the G mans to the northeast. From the 28th to the 31st the Germ stopped the advance of the I. Army, and their VI. and V Armies even aimed at forcing "the gap of Charmes," in such manner as to carry out an enveloping movement to the west the Vosges. This action was helped by ordering the XXI. Cor to take part in the battle of the Marne.

From these circumstances there resulted a series of very co fused fights extending over a large front between the Grande Co ronne and the Vosges. On Sept. 6, the German VII. Army, faci Dubail, was broken up, divided between the VI. Army and t German right then engaged on the Ourcq against Gen. Ma oury. But Dubail's army was also enfeebled by the remova the XIII. Corps to the west of the Oise; and at the same time t II. Army lost to the west the 18th Div. and the XV. Cor Evidently both sides had given up the idea of striking serious in Lorraine. After having gloriously held its positions to the e of Nancy and on the Meurthe, the II. Army was itself to broken up, to be reconstituted on the left of the French Armi in the "race to the sea."

Thus, after checks resulting from an inopportune offensiv the I. and II. Armies had been first able to stop the Germ progress; then to throw the enemy back to the frontier. M over, their merit was all the greater since they had been c stantly weakened by the withdrawal of their best units. Du ing the battle of the Marne they provided the unshakable pi of the vast movement undertaken by the Allies. It was than to their efforts that that movement succeeded. But they h paid the price. A single reserve division between Aug. 24 a Sept. 12 lost 140 officers and more than 5,000 men.

(B. E. P.)

III. BATTLE OF THE ARDENNES

On the outbreak of the World War, the III., IV. and French Armies concentrated towards the frontier, west of Meuse, covered by the VI. Corps in front of Verdun, and the Corps in front of Stenay. On hearing of the German attack Liége, Gen. Joffre decided to post the V. Army (Gen. Lanrez toward the Sambre and to direct the IV. Army, which he h grouped between Vitry-le-Français and Sainte-Menehould, the region of Stenay. The concentration, which had scarc begun on Aug. 8, was nearly finished on the 14th. Until t commander-in-chief had all his forces at hand, no one w allowed to be drawn into an important action.

The German high command had made a similar decisio hence the battle of the Ardennes was the "battle of the t blind men." However, on Aug. 10, a German mixed brig arrived near Mangiennes and was launched into a mad front attack against the advanced posts of the IV. Corps (III. Arm While all its attention was taken up with the attack in front brigade of the II. Corps (under Gen. Cordonnier, IV. Arm took it in the rear, and the German brigade was destroyed. Af this adventure, no German force made any further attem against the French covering troops.

French Plan of Attack.—The German plan of operatio placed the V. Army between Thionville and Tintigny, the IV between Tintigny and the Meuse de Dinant,[1] the III. Army b tween Dinant and the Sambre, the II. on the Sambre and the in the neighbourhood of Mons. The III. Army was still in th

[1] Name given to the Meuse between Mezières and Namur.

ennes behind the IV. and the I. Army was hastening towards ssels and Antwerp, when on Aug. 22 Joffre decided to attack. was certainly a strategic success to bring about a battle with is forces in the Ardennes, while the German III. Army was ble to take part in it. Joffre had disposed his III. and IV. ies in échelon, the left in front, so that he could face the h or east as he wished. On Aug. 16 he decided to attack to- ds the north with these two armies forming a rigid block, e the 7th Cavalry Div. reconnoitred towards Thionville, and 4th and 9th Cavalry Divs. to the north towards the Meuse. result was that in front, and almost everywhere, the Army ps had only weak and insufficient cavalry for reconnoitring poses. The liaison between the two armies was to be kept on axis Marville-Virton-Étalle.

uring the night of Aug. 20-1 the whole block moved for- d. The only instructions given by G.H.Q. were “ to attack enemy wherever met.” G.H.Q. estimated that the IV. y would have almost nothing in front of it, and yet it was isely there that the Germans had their IV. and III. Armies, III. being behind the IV. The Lorraine Army, which con- ed of the reserve divisions, groups under Gens. Pol Durand de Lamaze, was placed under the command of Gen. Maun- y with orders to defend the Hauts de Meuse, or eventually, he event of the advance of the III. Army, to besiege Metz Thionville. These reserve divisions were mobilised after active forces, the men were elderly, they had few officers, their staffs were inexperienced, so that the III. Army could little help from them.

n the evening of Aug. 21, after a long period, during which patrols had been encountered, the block arrived on the line a-Lagranville (VI. Corps), Tellancourt (V. Corps), Virton . Corps). At Virton the IV. Corps tried to get in touch the II., which formed the right of the IV. Army. The line of le continued by Villers-la-Loue (II. Corps), Geronville lonial Corps), Florenville (XII. Corps) and the Semoy (XVII. XI. Corps). The IX Corps had just arrived from the neigh- rhood of Nancy with the 17th Div. (Dumas); the Morocean . (Humbert) was not yet in line. The IV. Army (de Langle de y) was to push on towards the north, while the III. Army was over the right of the IV. Army against any attack coming n the north or east. Everywhere the advance was made in sions, except in the case of the II. Corps, which marched re on a single road.

n Aug. 22, all the columns started in a fog at a very early r for a long march with the idea of “ attacking the enemy erever met.” To march quickly rather than to take precautions the order of the day and almost everywhere the presence of Germans was only discovered by receiving shell fire. In the Army, the V. Corps sent its infantry to the attack without support of artillery, and it suffered such terrible losses that leaders became completely unnerved, and Gen. Grossetti, ef of the staff, had to intervene to prevent a precipitate re- at. In the IV. Army the Colonial Corps exposed a division in umn-of-route to the German guns. The XVII. Corps also ered from a sanguinary surprise. But the most serious danger se on the right wing of the IV. Army, uncovered by the pre- ture check of the IV. Corps at Virton; and on the right wing the III. Army, which was not covered either by the 7th valry Div. or the Pol Durand group of divisions.

ortunately the II. Corps was in a single column so that the division was able to make up for the absence of the IV. ps. On the right of the III. Army there was a leader, Gen. che, who with his heroic division gained the necessary time the other divisions to fall back. The Germans did not exploit r tactical success, but remained practically stationary in r positions. This battle of the Ardennes taught the French necessity for co-operation of all arms in the field of battle.

attle of the Meuse.—On Aug. 23, 24 and 25 the III. and IV. ies retired slowly without being disturbed. On the evening ug. 23 the front of the IV. Army was the line Montherme euse)-Montmédy; and that of the III. Army Montmédy- ncourt. On Aug. 24 they were a little farther to the rear, but not pushed by the Germans. A German staff commander, killed in his motor in front of Avioth, was found to have on him the orders given to the German IV. Army for the forcing of the Chiers and Meuse crossings on Aug. 26 and 27. The III. Army had obtained in a similar way information to the effect that the German 33rd Div. was to leave Metz and attack at Étain. A trap was set, but the Lorraine Army (reserve troops) was not equal to the task and the Germans escaped.

Lorraine Army Dissolved.—On the morning of Aug. 25, the right of the IV. Army retired between the Chiers and the Meuse; the III. Army also approached the Meuse facing eastwards. Thus the two armies practically became one, and it is regrettable that from this time they were not placed under one leader. On the same day, the IV. Corps (III. Army) suffered a severe check at Marville and they feared they would lose their corps artillery, but the II. Corps came to their assistance and convoyed this artillery to Stenay, where they crossed the Meuse. This shows how intimate was the co-operation between the two armies. It was on Aug. 25 also that Joffre gave the first orders which contained the real beginnings of the battle of the Marne. He decided to reinforce the left of the Allied Armies and to lose ground in order to gain the necessary time for his strategic plans. The Lorraine Army was dissolved; the Pol Durand group was to defend the Hauts-de-Meuse; Verdun and Toul were to have their respective mobile forces returned to them; the 55th and 56th Divs. were entrained for Montdidier. Gen. Maunoury had in these two divisions the nucleus of that VI. Army which appeared on the Ourcq and determined the victory of the Marne.

On the morning of Aug. 26 the entire IV. Army was on the left bank of the Meuse, protected on its left flank by the IX. Corps and the 4th and 9th Cavalry Divs. between Mezières-Rocroi and Signy-l'Abbaye, and forming the connection between the IV. and V. Armies. On its right flank it was in immediate contact with the III. Army, which was concentrated on the left bank of the Meuse with the exception of the 42nd Division. So much feared was the envelopment of the III. Army's right, that the 7th Cavalry Div. was sent to the rear to Dombasle, between Verdun and Clermont, as if an extensive enemy movement was expected to take place south of Verdun. The III. Army took no part in the battle of the Meuse; its 7th Div. was summoned to Beauclair in order to help the II. Corps on Aug. 27, but it was not engaged. On the same day the 42nd Div. was taken from the III. Army, reached Varennes, and then served as part of Foch's Army.

Defence of the Meuse.—On Aug. 26, the orders for the IV. Army ran: “ From to-morrow the IV. Army will fight a decisive battle on the Meuse. . . . The corps will make every effort to prevent any attempt of the enemy to cross the river.”

Generally speaking, the IV. Army was some distance from the left bank. Its object was to carry out vigorous counter-attacks against German infantry who had passed the river before its artillery could come to its support. The Colonial Corps was somewhat driven back by the Germans, who had crossed the Meuse at Inor and Pouilly, but the arrival of reinforcements from the II. Corps soon checked this. The struggle was severe on the whole front. On the right wing the II. Corps had decided successes, three times throwing the Germans back into the river at Cesse and Luzy. On the left wing, the success was still more marked. There the XI. Corps, reinforced by the 52nd and 60th Res. Divs., gained the battle of la Marfée. The German 16th Div., making the same mistake as did the French at the battle of the Ardennes, advanced in massed formation without artillery support and were crushed, leaving in French hands the flag of the 68th Prussian Regiment.

On the evening of Aug. 27 Gen. de Langle de Cary gave the following order: “ At all costs the Germans must be thrown back into the river Meuse. The successes gained by the offensive to-day make us hopeful that to-morrow will be equally successful.” However, Aug. 28 was not so active as the previous day; the Germans scarcely attacked at all, and the orders given by Joffre for the coming retirement to the Aisne kept the IV. Army to its ground. On Aug. 28 Gen. de Langle de Cary, in a general order, said: "The army inflicted heavy losses on the enemy, yesterday and to-day. It returns to the Aisne line, in accordance with orders received, to prepare for the offensive in a new direction." On the 29th the movements towards the Aisne commenced—the battle of the Meuse was ended. The French IV. Army had beaten the German IV. Army—a victory without a to-morrow, but certainly a victory.

Battle of Signy-l'Abbaye.—The French V. Army, having been beaten by the German II. Army on Aug. 22 and 23, had to retreat, leaving a gap 25 m. wide between the IV. and V. Armies. The Germans poured into this open space. The only known units were the advanced troops of the XII. Corps—it was really the III. Army commanded by Von Hausen. Gen. Dubois was ordered to fill up this gap and to cover the left of the IV. Army, and was given command of the IX. Corps, composed of the 17th Div. (Dumas), the Moroccan Div. (Humbert), and the 9th Cavalry Div. (de l'Espée). The 4th Cavalry Div. had been given up to the V. Army. Two roads led to the region occupied by the Germans at Rethel. The road Mezières-Rethel was barred by the 17th Div. and the 9th Cavalry Div. at Guignicourt, the road from Rocroi to Rethel by the Moroccan Div. at Signy l'Abbaye Launois.

On Aug. 28, the 17th Div., hearing the guns from la Marfée, had its attention drawn in that direction. On the same day, at 3 A.M., the advanced posts of the Moroccan Div. were attacked by the XII. (Saxon) Corps. At 11 A.M. the Moroccan Div. was turned in the west by the enemy, who seized Signy l'Abbaye and so opened up the way to Rethel. But the Germans did not exploit their success and allowed themselves to be checked at Novion-Porcien. The battle manoeuvres lasted through Aug. 29 and 30. Dubois, by clever movements, brought his forces to the north of Rethel, having thus accomplished his difficult mission. Again German strategy had not made the best use of its superior strength.

IV. CHARLEROI AND MONS

Charleroi and Mons are the names given to the battles fought by the French V. Army and the British Army respectively in the latter part of Aug. 1914, against the right and right centre of the Germans.

The French Position.—Inasmuch as the British did not come up into line until Aug. 22, it will be necessary to deal with the purely French situation first. Germany had declared war on France on Aug. 2 and the right wing had crossed the Belgian frontier on the 5th. By Aug. 20 1914 the forward movement of the German right-wing armies into Belgium, and the failure of the offensive of the French I. and II. Armies, had caused a modification in Gen. Joffre's original plan of campaign. Broadly speaking the intention now was to attack through Luxembourg and Belgian Luxembourg with the object of threatening the communications of such German forces as had crossed the Meuse between Namur and the Dutch frontier. This duty devolved primarily on the III. and IV.—*i.e.*, the centre—Armies of the French. In the south the I. and II. Armies were to make a secondary offensive between Metz and the Vosges to hold the enemy, who might otherwise be able to take in flank the French advancing through Luxembourg; and the French V. Army and the British Army were to act upon the offensive, though this offensive would depend almost entirely on success by the III. and IV. Armies to their right.

On the evening of Aug. 20 the French V. Army was either actually within, or entering, the area bounded by the river Sambre on the north and the river Meuse on the east. The junction of these two rivers formed a very marked salient; but so far from being a point of weakness this locality was at the moment of great strength. It was sealed by the strong Belgian fortress of Namur which was to be the pivot of an Allied right wheel in the projected offensive. On the 20th there arrived from G.H.Q. the orders for Gen. Joffre's new offensive. The ord were to the effect that all information pointed to the intent of the Germans to carry out an outflanking movement in north. The French III. and IV. Armies had been ordered march against the line Neufchâteau-Arlon. As for the V. Ar its task was to pivot on Namur and the Meuse, and to seek the main enemy mass in the north. On the left of the V. Ar the British Army would advance towards Soignies in the direct of Nivelles.

British Expeditionary Force.—When England declared war Germany during the night of Aug. 4–5 her forces available take the field consisted of a cavalry division, six infantry divisi and some battalions of line-of-communication troops, the wh forming the Expeditionary Force for service overseas. T Govt. decided to retain two divisions temporarily in the Uni Kingdom and to transport the rest of the Expeditionary Force France. The first ships sailed on Aug. 9 and, thanks to the p fection of the arrangements for mobilisation and transportati the operation was completed without a hitch by Aug. 18. John French, the British commander-in-chief, had reached headquarters at Le Cateau on the previous day; and his ar consisted of the I. Corps (1st and 2nd Divs.), Lt.-Gen. Douglas Haig; II. Corps (3rd and 5th Divs.), Lt.-Gen. Sir H ace Smith-Dorrien; and the cavalry division under Maj.-G Allenby, as well as line-of-communication troops. Concentrat was completed by the 20th, south of Maubeuge; and the p assigned to the British was on the left of the French V. Ar preparatory to the advance north of the Sambre towards Soign referred to above.

While his army was concentrating, Sir John French visi Gen. Joffre at Vitry-le-François on the 16th and discussed p sible alternatives of action depending on information of enemy's plans and dispositions. The main intention was, ho ever, to attack. Next day, French visited Gen. Lanrezac Rethel and there conferred with the commander of the V. Arm Lanrezac considered that it was not possible to carry out at o the order to attack, so far as it affected his V. Army. The wh of his troops had not yet come to hand. Then it had to be bor in mind that the British had not yet come up on the left, a that the action of the V. Army would also depend upon the su cess of the French IV. Army on the right. Lanrezac therefo confined himself for the moment to issuing orders for the occ pation of a defensive position by the X. and III. Corps, south the Sambre.

German Offensive Plan.—On this same day (Aug. 20), on t side of the Germans, a combined attack had been arranged which the II. and III. Armies were simultaneously to attack t French V. Army, from the north and east respectively. T German I. and II. Armies were to close up to the line reach on that day, and an offensive against the enemy west of Nam was to be carried out in co-operation with an attack by the I Army against the line of the Meuse between Meuse and Giv details being left for decision by the Army headquarters co cerned. As regards the British, the German Intelligence De was woefully at fault, for it was stated that a "disembarkati of the British forces at Boulogne and the neighbourhood mu be taken into account. It is the opinion here, however, that landing on a large scale has not yet taken place." At the tim two-thirds of the British force was within 30 m. of Gen. v Bülow.

During the day the Germans attacked the French detachmen on the Sambre. The events of the day had resulted in dislocati Lanrezac's preparations for the offensive, and at 12:30 P.M. wrote to Joffre as follows: "I consider it dangerous to let t V. Army cross the Sambre during the 22nd, minus, on the o hand, the I. Corps, which must hold the Meuse until the I Army has made sufficient progress north of Semoy, and minu on the other hand, the English who on the 22nd will not be ab to get farther than Mons." During the evening a reply came fro Joffre to say that Lanrezac could choose his own time for th offensive, and he accordingly decided that it would be launche on the twenty-third.

Early on the 22nd, fighting was resumed all along the French nt on the Sambre. The X. Corps was forced back, and during afternoon the road from Fosse to St. Gerard was crowded h artillery, infantry and transport moving southward. Fosse s occupied by the Germans about 8 P.M. Farther west the . Corps had likewise to give ground. Severe fighting took ce early in the afternoon round Chatelet, and both divisions d to retire, the 5th toward Tarcienne and the 6th to Nalinnes. 1 P.M. the III. Corps had definitely to renounce its grip on the thern outskirts of Charleroi.

As for the XVIII. Corps, it came upon the field, but was ith of the Sambre between Thuin and Malines instead of be-, as Lanrezac had hoped, on the Mons–Charleroi road in ich with the British. The Cavalry Corps of Gen. Sordet had len back during the night to Solre, and in the afternoon was it to guard the crossings from Jeumont to Thuin, and also hold the cross-roads at Merbes Ste. Marie on the far side of river. The night march following on long and arduous work Belgium had been fatiguing to the horses, and the cavalry ps was in need of rest. Joffre had prescribed that it was to ve to the British left, but Lanrezac considered that it was not a fit state to move until the twenty-third. It was not, how-er, until the evening of Aug. 25 that it arrived behind the t flank of the British.

To Lanrezac on the evening of the 22nd, the situation of the Army seemed grave, but by no means desperate. Only two of corps, the X. and III., had been engaged, and if these had fered heavily they had also made the enemy pay the price. thdrawn to more open terrain, where their artillery could der better support, they could re-form and, so he hoped, in ir turn take the offensive. Further, the I. Corps was intact and w becoming available on the right, as was also the XVIII. rps on the other flank; and the reserve divisions of Gen. labregue were coming up to support it. The British were now iving in position on the left, round Mons. In one way Lan-ac was much more fortunate than he knew. Von Bülow had acked prematurely by forcing the Sambre on the 22nd instead waiting for the attack of the III. Army against the Namur-vet section of the Meuse to take effect, and the retirement of V. Army during the 22nd had seriously discounted the German ances of enveloping it.

The British Army in Position.—The British Army had prac-lly completed its concentration on Aug. 21 and on the lowing day took up a position from Condé to Mons and nce southwest of that town, so as to be able to co-operate the forward movement, pivoting on Namur, as ordered by fre. As a matter of fact Namur had been attacked by the rmans and during this day was *in extremis*. This fact was, wever, unknown to French, who motored early in the morning m his headquarters at Le Cateau to visit Lanrezac at Phil-eville. To his dismay French, on entering the area of the nch V. Army, witnessed columns of infantry and artillery ving south. A British liaison officer reported that the Germans d forced the passage of the Sambre and were also making a le turning movement through Belgium.

French at once decided to give up the attempt to find Lan-ac and returned to Le Cateau. From there he despatched a ssage to Lanrezac to say that he was waiting for the French valry Corps to be posted on his left, as had been promised, and t he was prepared to fill the rôle allotted to him when the Army advanced to the attack. He also pointed out that his ition was much in advance of the line now held by that army d hinted that although prepared to carry out his rôle he could begin to do so until the French V. Army should recover ne of the ground already lost. Late at night a French staff cer from Lanrezac's headquarters confirmed the news of the ting which French had heard of during the day and asked if nch, by striking at the right flank of the German columns, ld thus relieve the pressure on the V. Army. The British nmander-in-chief considered that this was quite impracticable agreed to hold on to his position for 24 hours.

ituation on Aug. 23.—On the morning of Aug. 23—the day on which the battle of Mons was fought—the general situation of French and British was as follows: The French V. Army faced in two directions, east and north. The I. Corps was on or behind the Meuse, where all bridges had been destroyed except those at Dinant and Hastière. The X. Corps had its right on the high ground south of Fosse and Vitrivel, its left at Scry. The III. Corps (reinforced by a brigade from the XVIII. Corps) was deployed on the line Gerpinnes-Nalinnes-Claquedent. The XVIII. Corps was on the line Ham-Thuin, with detachments on the Sambre as far as Merbes-le-Château. The French Cavalry Corps was holding the passages of the Sambre from the left of the XVIII. Corps to Maubeuge. The 53rd and 69th Reserve Divs. (Gen. Valabregue) were about Solre le Château, and were to relieve the Cavalry Corps, which was to make for Maubeuge with the object of emerging eventually on the left flank of the British Army.

The British right flank was north of the Sambre between Erquelinne and Peissant. From here was the I. Corps—looking northeast—with its left near Mons. In front of the line, about Binche, was the 5th Cavalry Bde., which was subsequently withdrawn. The II. Corps carried on this line, from and including Mons, west of which there was a French division of territorials. The main body of the cavalry was in rear of the British left.

In this position of the theatre of war the I., II and III. German Armies were concerned. The German plan had been that the II. Army was to attack south across the Sambre, while the III. Army was to co-operate by attacking west across the Meuse, sending a strong force across the Meuse towards Rocroi to bar the French line of retreat. During Aug. 23, the I. Army (von Kluck) was to conform to this offensive movement. Gen. von Bülow had, however, made the mistake of attacking prematurely with his II. Army; the combined movement with the III. Army was unsuccessful, and consequently the trend of the fighting drifted westwards to where the advanced guards of the I. Army were coming into contact with the British on the Mons-Condé canal.

Battle of Charleroi.—In his published account of the battle of Charleroi, Lanrezac divides it into two distinct phases, the first from daybreak until 4 P.M., and the second from that hour until nightfall. In the first phase the course of the battle was as follows: The right wing of the X. Corps was driven back, and it reformed between Scry and St. Gerard; the I. Corps deployed on the high ground round St. Gerard with its right about Sart-St. Laurent. This operation was completed about midday, and the I. Corps was then well placed to act against the flank of the German Guard Corps, which was then attacking the X. Corps sharply. Gen. Franchet d'Espérey, commanding the I. Corps, instantly resolved to seize the opportunity and to attack *au fond*. His artillery prepared the way by an intense fire, and the Germans, apparently taken by surprise, suspended their attack to deal with this new danger.

It was now about 1 P.M. and Franchet d'Espérey was about to launch his infantry when disquieting news reached him from his right rear. The 51st Reserve Div., which had relieved the I. Corps on the Meuse, had failed in its task, and had allowed troops of the German III. Army to cross the river. The report went on to say that the reserve battalions had fallen back in disorder and that a detachment of the enemy had occupied Onhaye behind the V. Army. Franchet d'Espérey had no alternative but to suspend his attack and to send a division and a brigade to deal with the peril behind. Emboldened by the enforced inaction of the French, the Guard Corps again pressed on, its artillery maintaining a very severe fire. The French X. Corps and the fraction left of the I. Corps resisted energetically, with the result that in this portion of the field but little ground was lost, and connection was still maintained with the fortress of Namur.

While such was the state of affairs on the right wing, little was, in this first phase, taking place on the left wing. But after 4 P.M. a change for the worse set in, in that portion of the field. The left wing of the III. Corps was taken by surprise and driven back by a sharp attack, with the result that the whole III. Corps fell back in confusion, while the XVIII. Corps, with its right now uncovered by the retirement of the III. Corps, was forced to withdraw to the stream which runs from Thuilles to Thuin. The reserve divisions of Gen. Valabregue, however, had come up to Bousignies and Thirlemont. On the right wing, in this second phase of the battle, the X. Corps had been forced to admit a loss of ground, but it was only slight. As for the I. Corps, the portion left at St. Gerard was holding its ground.

During Aug. 23 Gen. Franchet d'Espérey had been called upon to deal with the presence of a detachment of the German III. Army which had forced its way over the river. Some sharp fighting took place, and about 10 P.M. the French infantry carried Onhaye with the bayonet. This attack by the French came upon the Germans somewhat by surprise, and the units of the III. Army on the right bank of the Meuse were in consequence retained there for the moment.

At the end of Aug. 23 Lanrezac came to the conclusion that immediate retreat was called for on the part of the V. Army. The chief causes of his decision are given by himself as follows: In the first place he had learnt definitely that the offensive of the IV. Army had failed and that the beaten troops were falling back to the Meuse with the left of the army on Mézières. The line of the river between that place and Givet was guarded by but a few battalions of reserve troops. The rear of the V. Army was thus threatened once again. In the second place Namur had fallen; in addition the roads on the right flank of the V. Army, already encumbered with thousands of civilian refugees, would be further blocked by the retreating Belgian troops from the fortress. Thirdly, the British Army was checked, and would in all probability be compelled to retire. Lanrezac, therefore, issued orders for the V. Army to retire on Aug. 24 to the line Givet-Philippeville-Beaumont-Maubeuge. Lanrezac's statement that his action was in part due to the conviction that the British would be forced to retire is a variant upon a previously held French opinion that such retirement actually preceded the retreat from Charleroi. How far both these statements are from the truth will now be seen.

The Battle of Mons.—The British position in detail was as follows: On the extreme left, about Condé, was the British 19th Bde., made up of battalions of line-of-communication troops in touch with a French division of territorials. Then came the 5th Div., while next on the right was the 3rd Div., holding a salient round Mons as far southeast as Villers St. Ghislain. The line was continued by the British I. Corps farther southeastwards to Peissant. The cavalry division was in rear of the British lef except the 5th Cavalry Bde., which was posted in advance of th right flank, but later withdrawn.

The British position was thus in shape somewhat like a broa arrow, with the two army corps practically at right angles to o another and facing, generally speaking, north and northea respectively. As matters turned out, the German attack w directed almost entirely against the II. Corps, and here on t left the situation was not unfavourable to the British, for t canal made a valuable defensive line, while the terrain on the f ther side held numerous difficulties for the attackers. Mud ditches and barbed-wire fences impeded their movement, a though, on the other hand, groups of trees and bushes gave cov from view and were of service for the enemy's machine-guns

South of the canal the crests of the high ground afforded t British useful sites for artillery, but the slag heaps of the num ous mines limited observation to some extent. The line of t canal, however, had one very disadvantageous feature: after ru ning from Condé to Mons in a mathematically straight line, forms a loop round Mons, thus constituting a marked salien Such a position might easily be found to be untenable, and S Horace Smith-Dorrien had prepared another and more defensi line in rear running through Frameries-Paturages-Wasme Boussu.

When day broke on Aug. 23 Von Kluck had three active cor and Von Bülow one, or about 150,000 men and 600 guns, with striking distance of the British force of some 75,000 men and 3 guns. The German I. Army was to march in a southeaste direction. The British II. Corps on the Mons canal was faci north. Consequently the left of Von Kluck's army must coll with the II. Corps in the neighbourhood of Mons. As a matt of fact the German commander was in ignorance of the positi of the British force. The march of the German I. Army, on t 23rd, was therefore shrouded in the fog of war, and, quite ear in the day, delay was caused by a report that Tournai was he by British troops. These were actually two French territori battalions, but, under the impression that they were Britis orders were sent to the IV., III. and IX. Corps to halt on t Leuze-Mons-Binche road, in view of the possibility that it mig be necessary to make a wheel to the right so as to envel Tournai. Later reports showed that the British were in streng on the canal, and that the troops at Tournai, now known to French, had retired toward Lille. The advance of the Germa I. Army was therefore resumed. But the orders for this resum

ion of the march were late in reaching the III. and IV. Corps, vith results that reacted on the German chances in the battle.

The left column of Von Kluck's army was the 17th Div. of the X. Corps, and its march was directed towards St. Symphorien nd Villers St. Ghislain. On the British side the I. Corps was on he line, generally, Harmignies-Peissant, and as it faced a gap etween the German I. and II. Armies its share in the battle of Ions was destined to be very small. It was shelled by German rtillery, covered in its advance by the 16th Dragoons, but the ritish casualties were slight. Of active fighting there was none ave for some spirited minor actions between the British divi- onal cavalry and cyclists on the one hand and German patrols n the other. The bulk of the day's fighting fell upon the salient ormed by the canal loop round Mons. So soon as Von Kluck ad grasped the real state of affairs his plan appears to have een to envelop both the British flanks while bombarding the ont heavily with his guns. The envelopment of the British left id not succeed, owing chiefly to the delay referred to above.

The battle opened in earnest about 10:30 A.M. with a bombard- ient by some batteries of the German IX. Corps which came ito action on a ridge to the north of Orbourg, and from that me onward the guns were gradually extended westwards as attery after battery, first of the IX. and then of the III. Corps, ime into action. At 1 P.M. the Germans had established a great iperiority of artillery against the front of the British II. Corps. he actual loop of the canal was held by the 4th Royal Fusiliers id the 4th Middlesex Regt., the former being responsible for ie bridge at Nimy while the right of the latter regiment held the ossing at Orbourg. At both these places the fighting was very vere, but the British musketry proved a terrible surprise to the ermans, who came on in masses which it was impossible to iss, and the British guns, though outnumbered by the German tillery, gave most effective support. Finally, however, the ermans were able through their superiority in numbers to ake a converging attack against the salient from the north and st, and the British were gradually forced back east and south- st of Mons. But the Germans were cautious about pushing to the town, and it was not until after 7 P.M. that the 84th egt. of the 18th Div. of the IX. Corps entered Mons, where it as thrown for a time into confusion by heavy fire. The British d Div. fell back to a line running east and west through ouvelles.

West of Mons the left division of the German III. Corps at- cked the left of the British 3rd Div.; and still farther west ong the canal the right division of the III. Corps, and later wards evening, the advanced guards of the IV. Corps, attacked e 5th Div. of the British. The retirement of the 3rd Div. from e salient round Mons inevitably led to a slight withdrawal of e 5th Div., and by nightfall the II. Corps was on a line which owed an average retirement of some three miles from the canal.

The Retreat Begins.—During the late afternoon and evening ench had been receiving disquieting news as to the situation the French V. Army on his right. At 11:30 P.M. a telegram rived confirming the reports, to the following effect: Namur d fallen during the day; the French V. Army had been heavily acked, and was falling back to the line Givet-Philippeville- aubeuge; Hastière had been captured by the Germans; the euse was falling rapidly and had added to the difficulty of ence. In these circumstances not only was the original offen- e out of the question, but the British line was now untenable. ench, therefore, decided to retreat to a previously reconnoitred e from Jerlain eastwards to Maubeuge, and orders were issued ordingly in the early hours of Aug. 24. The withdrawal was ected without serious loss, and for a moment French thought aking advantage of the fortifications of Maubeuge; but recol- ions of the fatal attraction of Metz for Bazaine induced him ass the fortress, and orders were issued at 3 P.M. on the 24th the retreat to be continued to the line Le Cateau-Cambrai.

V. BATTLE OF LE CATEAU

The battle of Le Cateau was fought by the left wing of the British Army on Aug. 26 1914, during the retreat from Mons. After Bavai the retreat was handicapped by the Forêt de Mormâl, which compelled the British Army during the 25th to march in two separated portions, the I. Corps east of the forest and the II. on the west. During the previous night the detrainment of the 4th Div. from England was almost completed; and it moved to its position towards Solesmes.

Meanwhile reports showed that the French were retiring all along the line, and Sir John French had now to decide whether to stand and fight on the line Le Cateau-Cambrai, or to continue the retreat at daybreak on the 26th. He decided that the retreat should be continued, and orders to that effect were accordingly issued. The order was complied with by the I. Corps, and after some delay caused by a violent attack by the Germans on Landrecies, the retirement was continued on the 25th in the direction of Guise. In the II. Corps, however, shortly after midnight Sir Horace Smith-Dorrien came to the conclusion that, in view of the fact that many of his troops had just completed over 20 hours of heavy and continuous work, and that the enemy were close along his front, it was out of the question to continue his retirement at dawn. He therefore issued orders to fight on the ridge just south of the Le Cateau-Cambrai road.

Disposition of the Forces.—The force at Smith-Dorrien's disposal was as follows, from right to left: The greater part of the cavalry was between Le Cateau and the Sambre; later it moved to the left flank to get in touch with the French I. Cavalry Corps, which was in the neighbourhood of Malincourt. Then came the 5th Division. The 3rd Div. held the centre as far as Caudry, and on the left lay the 4th Division. Thence to Cambrai was a gap filled by the 4th Cavalry Bde., and later by the French I. Cavalry Corps. The French 84th Territorial Div. was retiring slowly through Cambrai. Each British division had a front of approximately three miles. The 4th Div. was incomplete, lacking divisional cavalry, signal company, ambulances, ammunition columns and heavy artillery. The 19th Bde. was the general reserve.

The German force on the heels of the British was the I. Army whose commander, Gen. von Kluck, was the victim of faulty conclusions before, during and after the battle. He believed that the whole of the B.E.F. was opposite him; he thought that it was holding a position running north and south, whereas the line of the II. Corps was almost due east and west, and he was sure that it was either retreating or about to retreat in a westerly direction. His plan was similar to that which had been tried at Mons, a frontal attack mainly with artillery followed by enveloping movements against both flanks. The cavalry was to pin the British left until the German infantry should arrive.

The German Attack.—Soon after daybreak the British were engaged upon both flanks. On the right some German troops entered Le Cateau and confused fighting ensued, while on the left the 4th Div. became engaged with the enemy. Here the 4th Div., after defending an advanced position for some time, fell back slowly to a second line and brought the enemy advance to a standstill. These events were but preliminaries, and the battle of Le Cateau proper opened with a heavy bombardment, which grew in intensity as the artillery of four German corps came into action. The British artillery made a spirited reply, though heavily outmatched in numbers and weight of metal, and dealt severely with attempts of the German infantry to push forward. These attempts were, however, practically limited to the ground near Le Cateau on the British right, and to the village of Caudry, which now formed a salient in the centre of the line. Throughout the forenoon constant infantry attacks, varied by bouts of heavy shelling, were made against the latter village, from which about noon the defenders were forced out by artillery fire; but a counter-attack at once regained part of it and the German infantry advance was held up.

Until 1 P.M. the line of the II. Corps was everywhere intact in spite of the superior numbers arrayed against it. But on the right the situation was becoming grave, for the 5th Div., with its right flank uncovered by the retirement of the I. Corps, was being threatened by more and more German columns converging upon the field. Smith-Dorrien realised that at all costs the fight must be broken off if his force was to be saved. Orders were sent to break off the fight and to continue the retirement of the previous days. Before the orders for retreat had reached all concerned the British right had given way before overwhelming numerical superiority. But the Germans failed to exploit this success, and the withdrawal of the II. Corps, thanks largely to the devotion of the British artillery and to the arrival of the French I. Cavalry Corps on the left, was effected with less difficulty than had been expected. Smith-Dorrien successfully withdrew his columns and marched them swiftly to the Somme at and near Ham. By Aug. 28 the II. Corps was safely across the river.

The losses of the British had been severe, 38 guns had been lost, and the casualties were over 7,800, the 4th Div. suffering particularly. The retreat was practically unmolested, for Von Kluck hurried southwest instead of south, and thus missed a chance not likely often to occur in war.

VI. BATTLE OF GUISE

By Aug. 25 the succession of victories achieved in Lorraine, the Ardennes and on the Sambre had produced an atmosphere of optimism at German general headquarters. It was thought that forces might be safely diverted to East Prussia to deal with the Russian invasion. Accordingly, on the 26th, two corps and a cavalry division received orders to proceed to the Eastern Front. On the side of the Allies, on the other hand, it was imperative to take immediate steps to check the onrush of the German right wing. During the night of Aug. 25–6 Joffre issued a new directive concerning a "new mass of manoeuvre" to be formed on the left flank to carry out an offensive and to consist of the French IV. and V. Armies, plus the British as well as a new French army—the VI.—to be made up of units moved by rail from other sections, chiefly from the right.

On Aug. 26 Joffre and French had a conference on this proposed offensive at St. Quentin, at which the commander of the French V. Army, Gen. Lanrezac, was also present. British co-operation was, however, impossible, for on this day half of French's army was engaged at Le Cateau, where it was very roughly handled. On the following day Joffre promised that the French V. Army would be immediately directed to take the pressure off the British. Accordingly at 1 P.M. on this day an officer arrived at Lanrezac's headquarters with verbal instructions to attack at once and with vigour toward St. Quentin. The French V. Army was at this time retiring over the Oise above Guise, and the attack it was called upon to carry out was with the object of following on the left flank of the German I. Army in order to delay the German onrush.

French Support for the British Army.—Nightfall on Aug. 27 found the French V. Army behind the Oise with its left below Guise and its right about Rumigny, the whole facing generally northeast. Lanrezac's task was a difficult one. He had to suspend a retirement toward the south and convert it into an attack toward the west. At noon on Aug. 28 Joffre came to see Lanrezac at the latter's headquarters at Marle. Lanrezac pointed out his difficulties and explained that his right flank would be considerably exposed in the operation enjoined upon him; but Joffre peremptorily ordered Lanrezac to proceed with the offensive and even threatened to relieve him of his command.

The German Advance Delayed.—At daybreak on Aug. 29 the main body of the V. Army began to cross the Oise above and below Origny, but the plan had to be modified owing to an attack made upon the right east of Guise by two corps of the German II. Army. Accordingly Lanrezac decided to postpone the attack toward St. Quentin and to deal with the threat against his right flank first. It was, however, impossible to carry out this new plan and it was now decided merely to mask St. Quentin and to devote every effort to dealing with the German attack east of Guise. The main body of the V. Army, assisted by a cavalry division, carried out its task with vigour and about 5 P.M. general offensive took place along the 18 m. front from Origny Vervins towards Guise. During the night the two German corp fell back across the Oise. This success was somewhat neutralise by events between the Oise and St. Quentin, where the situatio took an unfavourable turn for the French.

Having carried out its task of delaying the Germans; th French V. army fell back during the evening of Aug. 30. Th operation had been skilfully carried out, but Lanrezac was n in favour with French general headquarters and within a fe days he was relieved of his command.

(F. E. W.*)

FROST, ROBERT (1875–), American writer, was born San Francisco, March 26 1875. His father was a New England and his mother was born in Edinburgh. In 1885 he moved wi his parents to Lawrence, Mass., studied in the public school and entered Dartmouth College in 1892, remaining there o year. From 1897–9 he was a student at Harvard, and from 190 11 taught English in the Pinkerton Academy, Derry, N. H., a then for a year taught psychology at the N. H. Normal Sch at Plymouth. In 1912 he went to England, where he remain three years and published his first two volumes of verse. On h return to America he retired to a farm at Derry and gave mu time to active farming. During 1916–20 he was professor English at Amherst College, Mass., a position which he resum in 1923. His poems portray in realistic fashion everyday count life in New England. Some of the work of his first volume h been denied publication for 20 years, and some of the second 10 years. He is the author of *A Boy's Will* (1915); *North* *Boston* (1915); *Mountain Interval* (1916); *A Way Out*, a pl (1917); *New Hampshire* (1923).

FRUNZE, MIKHAIL VASSILIEVICH (1885–1925), Russian s dier, was the son of a peasant who had settled in Turkistān and b come a surgeon. While at school he came in contact wi socialists, and on entering the Polytechnical Institute at Petersburg (Leningrad) he joined the Bolshevik group in t social democratic organisation. In 1905 he worked in the dustrial district of Ivanovo-Voznesensk and helped to organi the big textile strike of that year. He was frequently arrest and in 1907 was sentenced to four years penal servitude, and a subsequent six years on the grounds that he had offered arm resistance to the police.

At the end of 1914 his penal servitude was exchanged banishment to Siberia, where he was arrested for revolutiona activities in the following year, but soon afterwards escap from prison and the March revolution of 1917 found him Minsk at the head of an illegal organisation in the army. became president of a Front Committee, and later president Soviet in the provinces, and at the time of the Nov. Revoluti came to Moscow with a detachment of 2,000 men, with which took part in the fighting in that city. After the revolt in Ja slaw he became military commissar of that district, and in D 1918, commander of an army on the Eastern Front. He la became commander in chief of four armies and directed t operations against Admiral Kolchak. When the Eastern Fr was divided, Frunze became commander on the Turkistān s tion of it, where he surrounded and destroyed Kolchak's sou ern army. He afterwards took part in minor operations Central Asia, returning to Russia in Sept. 1920 when he to command of the troops that eventually drove General Wran out of the Crimea. For this he was rewarded with a swor honour and a portrait of Karl Marx. He then commanded military forces in the Ukraine. In 1924 he became vice-presid of the Revolutionary Military Council, and, in the absence Trotsky, the actual head of the Red Army. He became presid of this council and People's Commissar for Military and Na Affairs in Jan. 1925, but died before the end of the year.

FRY, SIR EDWARD (1827–1918), English judge (*see* 11.27 died at Failand, near Bristol, Oct. 19 1918.

FRY, ROGER ELLIOT (1866-   ), British painter and art itic, son of Sir Edward Fry, was born in London, and educated Clifton and King's College, Cambridge. He studied painting ıder Francis Bate and then in Paris, and exhibited at the Car-x Gallery, London, in 1903. His work, notably in his land-apes, is marked by deep feeling for form and a scholarly sense design and technical means. An active member and exhibitor the London Group, he gave an exhibition of his own paintings 1920. As a critic, with his wide knowledge and acute sensibil-, Fry became recognised in England and abroad as a leading pert. He published a study of *Bellini* (1899) and edited *ynold's Discourses* (1905), but is best known by his champion-ip through much opposition and prejudice, of Cézanne and the st-impressionists. Among other publications are *Vision and sign* (1920); *Architectural Heresies of a Painter* (1921), and a ok of travel impressions, *A Sampler of Castile* (1923). He was so joint editor of *The Burlington Magazine*.

FRYATT, CHARLES (1872–1916), British seaman, was born Parkeston, Essex, Dec. 2 1872. He entered the service of the eat Eastern Railway Co., and in 1904 became chief officer in eir service of vessels plying between Harwich and Rotterdam. 1913 he was promoted captain. At the end of July 1916, it ıs announced that his ship, "Brussels" had been captured d the captain himself arrested and tried by court martial, a charge of having attempted, on March 28 1916, to ram a erman submarine. The German authorities stated that Cap-in Fryatt had confessed that he had acted under orders from e British Admiralty; but the trial was hurried and secret, no ervention on the part of neutrals being allowed. The captain ıs condemned to death and shot at Bruges, July 27 1916. ıe body was, on July 7 1919, brought from Belgium to England d was buried at Dovercourt, near Harwich.

FUAD I. (1868–   ), King of Egypt, was born at the palace Gizeh, March 26 1868, the youngest son of the Khedive Ismail sha. After his father's débâcle Prince Ahmed Fuad, as he en was, went to Italy where his youth was spent. He returned Egypt in the 'nineties and was appointed aide-de-camp to Khedive Abbas Hilmi. He found outlet for his energies by esiding over charitable and educational institutions and was gely responsible for the foundation of the Egyptian Univer-y, of which he became president. In 1917 his elder brother, Sultan Hussein Kiamil died, and as the latter's son, Prince mal ed Din, renounced the rights of succession, Prince Fuad ame Sultan. After the termination of the British protec-ate on Feb. 28 1922, he was proclaimed King of Egypt arch 16). He had married on May 25 1919 the Princess Nazli, ughter of Abdel Rehim Sabri Pasha, a former governor of iro, and his heir, Prince Faruk, was born on Feb. 11 1920.

FUEL PROBLEMS (*see* 11.274).—The wood of our forests is r natural fuel. If we were restricted to that material, the ormous fuel demands of our industrial age would long since e razed our forests. As the dearth of wood made itself felt in lustrial districts, recourse was had to the fossil fuels which ture has stored up, coal and peat, and natural oil and natural s. Bituminous coal was the most important of these fuels, and iron industry required in particular those coals which gave a tallurgical coke suitable for replacing the wood charcoal in blast furnace. In some countries, for instance in Germany, own coal has of late almost broken the predominance of bitu-nous coal; brown coal is more easily mined and offers advan-es as household fuel when briquetted.

urther, modern industry and transport, established on the l-fuel basis, have recognised the advantages of liquid fuels their necessity for certain purposes. Oceanic navigation kes an increasing use of crude oils; automobile and aerial tors are no longer to be thought of without gasoline fuel. ain, the cleanliness and precision attainable with gaseous ls in furnaces and in the preparation of valuable products, e secured to these fuels a preferential position in the produc-n of steel and in the manufacture of glass and of ceramic ects. Extensive systems of gas-pipes distribute gas through ns and industrial centres, even across states.

But the natural fuels, solid, liquid and gaseous, are by no means evenly distributed over our globe. Consequently we are forced to produce the required fuel from other sources, to meet local conditions, unless we are satisfied to depend upon imported fuel. The chemist and engineer are hence confronted with the problem of converting fuels of locally lesser value into fuels for which there is a greater demand. Thus arise many problems, the most important of which is the conversion of coal into oils.

I. GASEOUS FUELS AND THEIR PRODUCTION

From Solid Fuels.—The constitution of the gaseous fossil fuels is easily determined; for the molecules of gaseous substances are generally the smallest and the least complex. The combustible constituents of natural gases, exhaled as natural gas or fire-damp, are almost exclusively represented by methane, CH_4. The methane may have originated from residues of a fossil flora or fauna. The biological processes which resulted in the formation of petroleum took place under scission of methane, which was also produced during the formation of coal and during its natural ageing. Natural gas is therefore found in association with oil-fields and coal seams. As, however, natural gas is not replenished at the rate at which it is consumed in some industrial districts (*e.g.*, Pennsylvania), many works which originally relied upon natural gas have been obliged to adopt producer gas as their fuel. The chemical constitution of gaseous fuels is easily ascertained, and also the production of gaseous fuels from liquid and solid fuels offers no particular difficulties.

Dry Distillation.—For the preparation of gaseous from solid fuels two chief methods are now available. The so-called dry or destructive distillation of coal is historically the first. The gas formed by the thermal decomposition of the coal consists, when the temperature is kept as low as possible, essentially of methane and other hydrocarbons. When the coal is discharged into glowing retorts, as in gas and coke-oven works, the gas liberated will be the richer in hydrogen the higher the temperature. This method of coal distillation furnishes a gas of relatively high calorific value. With low temperature carbonisation, the calorific value may rise to 9,000 calories per cu. metre; at higher temperatures, the figure will lie between 4,000 and 5,000 calories. But the volumes of gas are comparatively limited; only a small portion of the coal substance is gasified, the bulk being transformed into coke. The yield is about 60 to 70 cu. metres of low temperature gas per ton of gas coal, and some 200 or 300 cu. metres of coke per ton. The complete gasification of coal cannot be effected by heat alone. The coke produced by the distillation must be gasified by chemical reactions. This can be done in three ways.

Chemical Reactions.—The reaction of air with white-hot coke yields a gas, theoretically consisting of two parts of carbon monoxide and four parts of nitrogen; this gas is of low calorific value. The reaction $2C+O_2=2CO$ proceeding under considerable liberation of heat, the manufacture of such a gas—air-gas—can be easily carried out continuously in shaft furnaces. The best material is coke; coal may be used provided it does not cake; brown coal briquettes are also suitable. From the standpoint of gas production, the ordinary pig-iron blast furnace may be regarded as a huge air-gas producer, with the difference that the oxygen required for the production of carbon monoxide is taken not only from the blast, but also from the iron ores. This process of coal gasification, the air-gas process, is associated with a pronounced liberation of heat.

Water-Gas Process.—In the water-gas process, however, the reaction $C+H_2O=H_2+CO$, heat is consumed and has to be replenished to sustain the process. The water-gas process can therefore not be carried out continuously in a shaft furnace unless external heat be supplied. The process is hence worked discontinuously. During the first hot run the coke charge is raised by the air blast to a temperature of about 1,000°C.; steam is then admitted, heat is absorbed and water-gas is produced, while the temperature of the layer of glowing coke sinks gradually. When the temperature has fallen a few hundred degrees, the hot-air blast is again turned on.

Mixed Gas Process.—Since the air-gas process liberates heat whilst the water-gas process absorbs heat, technical practice began to combine the two processes before the theory of the reactions was understood. Gas generators were worked with air and steam. Numerous advances have been made during the last decade in the domain of fuel gasification, particularly with regard to the difficulties caused by the use of coal instead of coke in the generation of both mixed gas and water-gas.

By the use of considerable additions of steam we have, in the mixed gas process, further learnt to recover the bulk of the nitrogen contained in the coal, in the form of ammonia (*see* AMMONIA). Success has also been achieved in the perfection of gas producers as economical apparatus for the manufacture of primary tar. The total gasification of the coal and coke has so far laboured under the disadvantage that, as the daily throughputs of gas producers were relatively small, a good many furnacemen and a good deal of stoking were required. Recently gas generators have been built for daily throughputs of 100 tons. This working in large units is one of the most important problems of coal gasification.

From Liquid Fuels.—Further substitutes for natural gaseous fuel can be obtained by the thermal decomposition of liquid fuels, such as crude oils or certain fractions of these oils, gas oil, tars or tar-fractions. The carburation of water-gas is a case in point. Water-gas does not burn with a luminous flame and its calorific power is low; it is therefore carburated by the injection of crude oil or tar oil into incandescent chambers. At temperatures above red glow the oils are decomposed, to a large extent, into gases, some tar and coke. The gases consist of very diverse hydrocarbons of higher calorific values than the water-gas. By mixing the two kinds of gases the water-gas is therefore enriched. In the early days the gas was carburated also for the purpose of rendering it luminous. With the invention of the Welsbach incandescent burners this application has lost its importance; but carburation for the sake of increasing the calorific value still remains important.

The thermal decomposition of oils is practised for the general purpose of obtaining gases of high calorific power. Thus tar or oil gas is manufactured by the decomposition of so-called gas oil. It served chiefly for lighting railway carriages, but is being replaced by electric illumination. The gasification of liquid, relatively inferior fuels, by the aid of steam might become valuable under certain conditions for the preparation of a water-gas rich in hydrogen, by a kind of water-gas process. Thus, petroleum vapours mixed with steam and heated to 1,000° in the presence of bauxite as catalyst can be converted into a mixture of carbon monoxide and hydrogen, which high-pressure catalysis further transforms into synthol and similar products.

From Other Gaseous Fuels.—It may happen that natural gas is available, but that hydrogen is needed. The conversion of methane into hydrogen may be effected catalytically by passing methane through tubes or kilns at the high temperature of 1,000°, when methane is decomposed into hydrogen and carbon. At lower temperatures the decomposition is incomplete. When shaft furnaces are used the carbon deposited can subsequently be burnt out again by blowing hot air into the furnace; the heat liberated is re-utilised to raise the furnace again to the high temperature and to decompose more methane. Like the vapours of liquid fuels (though less easily, owing to its high stability) methane can also be converted, by means of water vapour in the presence of bauxite as catalyst at about 1,000°, into a mixture of carbon monoxide and hydrogen.

The reversed process should finally be mentioned. If desired, the carbon monoxide contained in some available fuel gas mixture can be removed by transforming the carbon monoxide catalytically, at low temperature, into methane, with the aid of the hydrogen in the mixture. This was done experimentally about 1915. The process has not been adopted, however, although the elimination of the monoxide from illuminating gas seemed hygienically advantageous. The catalytic preparation of pure methane from water-gas, tried on an industrial scale some years ago, still remains in the preliminary stage, because the purification of the gas (of sulphur) and the partial remo of the carbon monoxide proved too expensive. Such a proce moreover, involves a loss of about 25% in calorific value, becau the proportion of methane, represented by the theoretical m ture of carbon monoxide and hydrogen, possesses only thr quarters of the heat value of the four times larger volume $(CO+3H_2)$ which it replaces. The reason is that this metha formation is a strongly endothermic process.

Purification of Gaseous Fuels.—For many purposes the a ficial gaseous fuels require careful purification. Thus, the escaping in large volumes from the mouth of a blast furna has to be freed of all the dust it carries before it can be fed i internal combustion engines. The object is attained by mecha cal cleaning and dust separation, by means of filters, centrifu machinery or sprinkling with water. The electric dust preci tation by the Cottrell process should especially be mention (*see* FUME PRECIPITATION). The removal from the gases of sulphur compounds is frequently a difficult problem. It is chie required in the case of illuminating gas, and the sulphur can recovered in a utilisable condition. The old-established meth purifies the gas by means of iron ore (bog ore). Activated bon has recently been experimented with for the same purpo The gas is mixed with a sufficient amount of air to oxidise sulphuretted hydrogen in the gas into sulphur; the sulphur retained by the carbon, and the process is accelerated if ammo is present in the gas. The activated carbon impregnated sulphur is then extracted with ammonium sulphide; the eva rated solution leaves the sulphur as a marketable residue. most of the catalytic processes removal of hydrogen sulph alone from the gas is, however, insufficient. The other sulp compounds, notably carbon disulphide, must also be eliminat

II. LIQUID FUELS AND THEIR PRODUCTION

The natural liquid fuels, natural oils or petroleums, occur widely-diverging compositions, and are partly aliphatic, pa naphthenic in character; aromatic compounds are found in so kinds of petroleum. The natural oils are also classified acco ing to the nature, asphaltic or paraffinic, of their high-boil residues.

As regards the origin of petroleum, the biological hypoth of Engler has found general support. According to this, pe leum was formed in the course of time by the decomposition the fatty constituents of small and large organisms. The opti activity of certain petroleum fractions is regarded as afford a strong argument in favour of this view. That, however, liq hydrocarbons, with which we are essentially concerned, may prepared artificially in other ways and might naturally h been produced in such ways under certain conditions, has b established within this century, by chemical research in vari cases. There are, *e.g.*, carbides, such as uranium carbide, w liberate liquid hydrocarbons when decomposed. It is furt known that acetylene and hydrogen may catalytically be c bined to form petroleum-like products; and within the last years it has been shown that the high-pressure synthesis water-gas leads to the formation first of synthol and furt when this synthol is heated under pressure, of an artif petroleum. Whether or not petroleum has been formed in s localities by inorganic reactions of cognate nature, cannot proved, but the possibility cannot be excluded.

From Solid Fuels.—Heating of geologically recent coals un exclusion of air seems to be the simplest method for the pro tion of liquid fuels from solid fuels. Destructive distilla yields, in addition to the gases mentioned and to the resi coke, a tar which, when formed at low temperature, cont constituents of petroleum character. The proportions of s tar obtainable are considerable. Gas coals of more recent logical periods (ordinary coal) yield up to 12% of the tar, ca coals still more. Certain lignites and oil shales are like suitable materials for the manufacture of the tar by distillat The Scottish shale-oil industry and the brown coal carbo tion works of central Germany operate on these lines.

The large bulk of the tar which comes from our coal gas

ke works is of a different composition. Owing to the high
mperatures which are used in gas-works and especially in coke-
ens, in order to secure high yields of both gas and a firm coke,
tars are essentially aromatic in character and rich in ben-
e, naphthalene, anthracene, etc. By weight the chief product
n either case semi-coke or coke. The tar yield referred to the
ght of coal, lies in general between 12 and 3% (*see* Coal Tar
oducts).

Bergius Process.—Since coal contains only 5% of hydrogen
average, whilst petroleum contains more than twice as much,
increase in the oil yield from coal seems dependent upon a
ply of hydrogen. In the Bergius process for the liquefaction
coal, hydrogen is made to react with coal at a pressure of
re than 100 atmospheres and at temperatures of about 450°.
e coal is ground and kneaded with 30% of tar into a paste;
s paste is continuously pressed into the high-pressure auto-
ve. We may imagine that the coal is first carbonised, the
mperature being sufficiently high for this purpose; the prod-
s are primary tar and semi-coke. The semi-coke is further
drogenated and half of it, by weight, is converted into oil.
at the reaction may proceed in this way has quite recently
en established by experiments in which the carbonisation
s effected at ordinary pressure, and only the hydrogenation
the semi-coke was carried out at high pressure. This "ber-
nnisation" is not equally applicable to all types of coal.
table materials are particularly coal of comparatively recent
iods, rich in volatile constituents, but not inclined to cake.
ch coals which are popular as fuel for gas generators, but in
neral unsuitable for coking, yield about 50% of oil by the
gius treatment, whilst low-temperature carbonisation would
the best give 10 to 12% of oil. The oil of the Bergius process
ot equal in value to natural oil. It contains, it is true, ample
portions of gasolene, but it also contains about 20% of
nolic constituents, and is hence more closely related in con-
ution to the primary tars than to petroleum. The Bergius
cess, which is expensive owing to the high-pressure apparatus
uired, offers advantages in localities in which there is no
rket for semi-coke, neither as domestic fuel nor for gasifica-
or the manufacture of powdered fuel. Under other con-
ons, improved methods of low-temperature carbonisation
l be serious competitors.

rom Other Liquid Fuels.—Natural, as well as artificial liquid
ls contain in general fractions of almost all boiling points,
ging from ordinary temperature up to 400°. Not all these
ctions are, however, in equal demand. In the 19th century
ip and illuminating oils, boiling between 150 and 250°, were
most valuable petroleum constituents. Since then electric
l incandescent lighting on the one hand, and the develop-
nt of automobiles, flying machines and industry generally
the other, have increased the values of the low-boiling ben-
es and of the lubricating oils in petroleum, so that the evalua-
of the various petroleum fractions has altogether changed.
present the supply of benzene from petroleum is not sufficient
satisfy the demand. Fortunately the high-boiling constitu-
s of petroleum can be converted by cracking processes into
-boiling motor spirits. One-third of the gasolene wanted in
erica for automobiles is said to be now produced by cracking.
e the oil-gas production mentioned above, cracking involves
ting of high-boiling oil fractions up to incipient decomposi-
. The cracking process is, however, conducted at lower
peratures, in the neighbourhood of 500°, and under pressure,
ause less gas and more vapours of gasolene type are formed
n the pressure is raised. This heating up to partial thermal
omposition of oils of high boiling points is important in other
pects. In the Diesel motor (*see* Internal Combustion
GINE), it is believed, the air is first heated by the compression
ke to cracking temperatures; the oil injected into this hot
is then thermally decomposed and burns in the compressed
separate ignition of the fuel can be dispensed with.

he dearth of low-boiling gasolene has induced designers of
omobile internal combustion engines to use fuels con-
ing high-boiling constituents. These constituents, however, are apt to ignite by the heat due to compression toward the end of the compression stroke and before the dead point is passed. The piston is then forced back and "knocking" occurs. This pre-ignition of gasolene-air mixtures seems to be favoured, if not caused, by the fact that the carbon deposited on the engine cylinder always carries some iron. The tendency to knocking is suppressed by adding to the motor spirit substances such as lead tetra-ethyl which, it is assumed, act by being adsorbed by the ferriferous carbon in the cylinder; the carbon is thus catalytically poisoned and cannot produce knocking. The anti-knocking reagents are, however, dangerous to the human system, and not likely to find favour. The best way of stopping the knocking trouble would be to return exclusively to motor fuels of low boiling points. The world's production of benzene is insufficient for the demand. Synthetic preparation of benzenes may bring the desired solution of this problem.

Some artificial liquid fuels can or should be improved or modified, wholly or partly, before utilisation. Half of the oil fraction of primary coal-tar consists of phenols for which there is little demand. By means of hydrogen at 700 to 800° they can be reduced to the more valuable benzene and toluene. Certain hydrocarbon fractions of primary tars are highly unsaturated; they can be hydrogenated and rendered more valuable in similar ways. The naphthalene of coke-oven tar can be converted into a liquid fuel, tetrahydronaphthalene, commercial tetralin. For this purpose the solid naphthalene is fused, purified by crystallisation and freed of the last traces of sulphur by treatment with metallic sodium. The naphthalene thus purified is then submitted to hydrogenation by means of hydrogen under pressure in the presence of nickel as catalyst, somewhat as in oil hardening; but the product, tetralin, is liquid.

Attempts have also been made to convert high-boiling liquid fuels and also tar and pitch into low-boiling motor spirit by the Bergius process, analogous to cracking but combined with hydrogenation. The process has not found industrial application, apparently because the American cracking processes attain the same object by less expensive means.

From Gaseous Fuels.—Gaseous fuels frequently contain vapours of liquid fuels of low boiling points. Natural gas, for example, very frequently, though not always, carries higher homologues of methane. There are benzene vapours in coke-oven gas, and the gases of low-temperature carbonisation retorts contain vapours of benzene character. These vapours can be removed and recovered by physical methods, scrubbing the gas with oil or treatment with adsorbents, such as activated carbon and recently also silicagel; the use of the latter reagent is so far largely experimental. These vapours are further condensed by cooling or by compression, or by a combination of the two methods. Both methods yield the liquid directly; in the former cases the oil or activated carbon used for the scrubbing or adsorption must afterwards be submitted to steam blowing in order to obtain the liquids.

The object of these processes is simply the recovery of fuels of low boiling point already present. Methods for the synthetic preparation of such fuels have been developed within the past few years. The process is a high-pressure catalysis, starting with carbon monoxide, utilised suitably in the form of a mixture of monoxide and hydrogen, a water-gas containing an excess of hydrogen. A mixture of one part of carbon monoxide and two parts of hydrogen is first carefully purified, especially of all sulphur compounds, and then compressed to about 150 atmospheres. At this pressure and a temperature of about 400°, the mixture is passed over the catalyst, for instance, zinc oxide or chromium oxide. The hydrogen is bound by the carbon monoxide and the reaction $CO+2H_2=CH_3OH$ yields almost pure methyl alcohol. Provided disturbing metals, particularly iron which would form iron carbonyl, be absent, no undesirable secondary reactions likely to diminish the alcohol yield seem to take place. Formation of methane, an undesirable reaction, would be aided by the presence of iron.

This synthesis of methyl alcohol hardly concerns the fuel problem. The alcohol contains almost 50% of oxygen, its calorific value is about half that of benzene or gasolene, and it is not a motor fuel.

Higher Alcohols.—In the case of the higher alcohols, it is possible to prepare mixtures of those alcohols and ketones by high-pressure catalysis, starting with the same raw materials, carbon monoxide and hydrogen, but resorting to other catalysts. These alcohol mixtures of oily character (*i.e.*, little soluble in water) which may be designated by the general term "synthol," can, for instance, be produced with the aid of iron impregnated with potassium carbonate as catalyst. Ninety percent of this synthol boils below 200°, and it forms an excellent motor fuel, at least equal in value to benzene and gasolene. For the present the synthol process is too expensive. But in the future synthetic motor fuels must be prepared in this or similar ways. Water-gas can be produced from all types of coal and peat. It is therefore possible to manufacture synthetic motor fuels in all districts where some coal but not petroleum is available. This source of fuel would provide for the time when petroleum and petroleum products fail. We have more reliable knowledge as to the occurrence of coal than about oil-fields. The coal resources of the globe will probably hold out for many centuries.

III. SOLID FUELS AND THEIR PRODUCTION

So far man essentially relies on fossil, chiefly solid, fuels for obtaining heat and power. Chronologically these fuels may be classified as peat, brown coal and coal. A discussion of their genetic interrelations is unnecessary. The earlier view which traced the genesis of coal to cellulose is giving way. Microscopical examination of coal indicates that coal is the decay-product of wood. Decay of wood, biological researches teach us, is due to certain fungi; they work by destroying the cellulose, which is transformed into gaseous and water-soluble products, whilst they leave the lignin essentially intact. Chemists have proved that the lignin and the carbon constituents proper of brown coal and coal possess a similar chemical constitution, that is to say, a cyclic structure.

The assumption is, then, that the main constituents of our fossil fuels have been formed by a slow decay of lignin, during which the essential chemical character of the lignin was preserved. Cognate interesting conclusions have been arrived at concerning the bitumen in coal. It would appear that the bitumen of the highly diverse brown coals consists mainly of fatty acids of high molecular weights and of odd numbers of carbon atoms, whilst the biologically easily digested fatty acids, which predominate in the fats of plants and animals, contain an even number of carbon atoms. We may hence assume that the fatty acids of the mother substance of coal, which are easily destroyed in a living organism, have disappeared, whilst the more resistant fatty acids of odd carbon-atom numbers have survived and have been utilised in the formation of bitumen.

The solid fuels—coal, for example—cannot always be used in the form in which they are won. According to requirements solid blocks are broken up and sifted into the desired sizes, or ground up and atomised to yield convenient powdered fuels. Conversely, small coal is rendered more marketable by briquetting; this applies particularly to the lignites, whose moisture of 50% is first reduced to 15%.

Apart from these mechanical modifications, other methods of improving solid fuels have of late acquired importance. Metallurgical coke was first made in coke ovens merely as a substitute for charcoal. The enlargement and perfection of the blast furnace called for a firm, little breakable and friable coke. Then the quality of the coke had to meet higher claims. What is wanted is absence of sulphur compounds. To a slight extent the sulphur is removed with the pyrites when the coal is washed. A complete elimination of the sulphur has been attempted by treating glowing coal with hydrogen; the process has not yet been adopted, chiefly, perhaps, because the purification is not complete, in spite of its high cost. Meanwhile, however, ways have been discovered of controlling the combustibility of the coke. The blast furnace requires an easily combustible coke, the cupola a coke which burns slowly. The former coke can, in general, be obtained by accelerating the coking process and by avoi subsequent heating, whilst high coking temperatures and coking periods favour the formation of a sluggishly burning c

The semi-coke obtained when temperatures of 500 to are not exceeded in its production is readily combustible. in a handy, dense and little friable condition, this semi-c the so-called smokeless coal, would represent an ideal fuel. produce such a semi-coke which will not require subsequent quetting is one of the most important problems of the fut considerable progress has been made in the solution of this p lem during the past few years.

The production of solid from liquid fuels is, as a fuel probl a matter of secondary importance. Retort graphite is produ by decomposing the tar vapours and the hydrocarbons of in gas retorts. Petrol coke, so-called, is obtained by cok petroleum pitch. Both these cokes are products of consider value for the manufacture, *e.g.*, of carbon electrodes; but t do not count as fuels. The soot prepared by the decomposit of vapours of liquid fuels, a high-priced form of carbon, is utilised in the manufacture of electrodes.

Reference should finally be made to the preparation of s from gaseous fuels. Here again a soot process should be m tioned in the first instance. Carbon black is obtained by incomplete combustion of natural gas; the process is waste however, and is only applied when the gas cannot be utili in other ways. Better results can be secured by the catal decomposition of carbon monoxide. This method has not found any serious industrial application, but it deserves att tion in cases where a carbon absolutely free of sulphur is wan The process might be developed in promising directions, si the decomposition of the monoxide $2CO=C+CO_2$ yields bon dioxide which cyclically can be reduced to monoxide ag The essence of the process is therefore an intermediate gasi tion of impure coke for the preparation of pure carbon.

See "Fuel and Power Generation," in *Rogers' Manual of dustrial Chemistry* (4th ed., 1925). (F. F

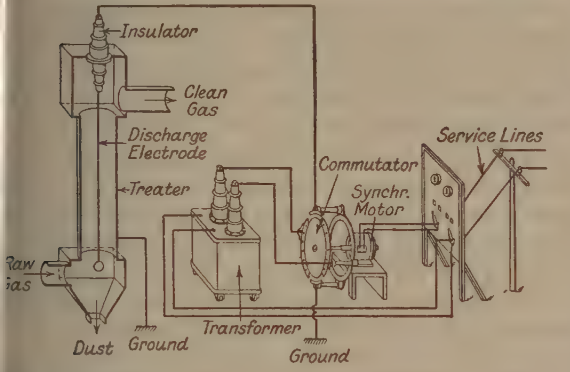
FULLER, JOHN FREDERICK CHARLES (1878–), B ish soldier, was born Sept. 1 1878 and gained a commissio the Oxfordshire and Buckinghamshire Light Infantry After active service in the South African War, he relieved tedium of peace-time soldiering by extensive scientific and ph sophical studies, and gained a considerable reputation as authority on Hindu mysticism and the Hebrew Kabbalah. Th studies provided an unusual groundwork and mental eq ment for his military researches later. In the World War, holding a variety of staff appointments, he became chief ge staff officer of the Tank Corps in April 1917. He had a resp ble share in the project for the great tank surprise at Cam in Nov. 1917, and in the tank successes later, until in July he was brought back to the War Office to organise the vast expansion then contemplated for 1919, had the war contin

Developing his ideas after the Armistice and preaching new gospel of war, Colonel Fuller was for a time criticised tank extremist, an unpractical visionary. Abroad, however, views were acclaimed, by the French general staff, who tra lated and circulated them throughout their army, as "an ex vision of the future." Gradually, however, his prophecies his teaching permeated the army, gaining power from his pointment, in 1922, as chief instructor at the Staff College, still more when, in 1926, he was appointed military assistant the new chief of the Imperial General Staff. The result of researches into the science of war is incorporated in his *Foun tions of a Science of War* (1926), and among numerous ot books, his *Tanks in the Great War* (1920), *The Reformation War* (1923), and *Sir John Moore's System of Training* (19 attracted wide attention (*see* STRATEGY).

FUME PRECIPITATION, ELECTRICAL.—The precipita of smoke by electricity was described in 1824 by Hohlfel teacher of mathematics in Leipzig, but only after it was in pendently rediscovered and critically studied by Sir Oli Lodge about 1884 did it attract general attention and lead attempts at industrial applications. At the time, howe

;e proved unsuccessful due to the lack of modern equipment. 'as not until 1906, following experiments at the University California, that the process was commercially successful. 'he first installation was at the Selby Smelting Works, near Francisco, where it was used for the removal of sulphuric l mist from about 5,000 cu. ft. of gases per min.; it was still peration there in 1926. By 1910 a plant to remove dry dust fume from 250,000 cu. ft. of gas per min. was built at an-er smelter, and in 1912 the process was successfully extended he removal of cement dust at nearly a red heat from 250,000 ft. of gas per min. at the Riverside Portland Cement Com-y. This mill, of 2,500 bbls. daily capacity, situated in the rt of the Californian orange groves, had been threatened with ıl closure as a nuisance because of the dust emitted.

'he electrical method as there installed removed 98% of the t, the daily catch being about 100 tons, aggregating for these years of operation over 350,000 tons, equivalent to a train of y loaded freight cars 100 kilometres long. Although first applied mitigate nuisances, the demand for the process to-day is marily based on a greater profit to be derived from the gases ıned or the material removed. At one time during the World ır, even the Riverside plant was making more profit from ash incidentally recovered in its dust than from its cement.



'IG. 1.—Apparatus for the electrical precipitation of dust or ›ke from gases.

Research Corporation.—Another circumstance aiding the de-opment through friendly public interest was the creation in 2, under the auspices of the Smithsonian Institution, of the search Corp. in New York City, to hold and administer as an lowment for research most of the United States patent rights the process. The corporation besides supervising construc-n and development of this particular process, also serves in ıeral as a clearing house for information and as an intermedi- and trustee between inventors, the industries and the public.

The Process.—Technically the process consists in securing a iform, copious but non-disruptive discharge of electricity m small electrode surfaces of one polarity into a stream of udy gas. The fine solid or liquid particles composing the dust, ne or smoke are immediately attracted to, and deposited on, ge electrode surfaces of opposite polarity, the particles having ome charged from the condensation on their surfaces of a ction of the electricity passing between the electrodes. The ›cess is diagrammatically illustrated in fig. 1. Alternating rent from service lines is stepped up in a transformer to a h voltage and then converted to a direct, or rather a pulsating directional, current by a commutator or "rectifier" driven a synchronous motor. One side of the line is grounded and ınected to a pipe or "treater" carrying the fume-laden gases. is pipe serves as the collecting electrode. The other side of the terminates in a wire serving as the discharge electrode, which ıung axially within the pipe. Voltage is regulated to secure as ong a glow as corona discharge from the wire electrode as ssible without passing over into a disruptive discharge, *i.e.*, spark or arc. This adjustment is easier when the discharge ctrode is the negative, though either polarity may be used.

The gas treaters now in general use consist either of a multiplicity of pipes similar to that in the figure, or of plates hung vertically in a flue, the wires being stretched parallel between them. The materials of construction, including the collecting electrodes, vary from iron and lead to reinforced concrete and vitrified earthenware, depending on the composition and temperature of the gas stream to be treated.

Factors in Design.—Most plants are designed with electrodes of opposite sign 2 to 6 in. apart and operating at 30,000 to 80,000 volts. The size of installation is determined primarily by the volume of gas to be treated and the percentage of suspended matter to be removed, the amount, kind and size of particle of the latter being of minor importance. If P is the ratio of outgoing to incoming suspended matter, t the average time in seconds that the gas remains between the electrodes, and K, a constant depending upon the apparatus, voltage, temperature and kind of raw gas, then $P=K^t$. In most commercial practice t averages about 2 seconds and K varies from 0·2 to 0·7, the gases travelling from 10 to 40 ft. through the electric field of linear rates of 3 to 15 ft. per second. Removal of 90% to 99% of the suspended matter is usually aimed at, and the energy required is 1 to 3 kw. hours per 100,000 cu. ft. of gas treated.

Industrial Uses.—The earliest applications of the process were to the smelting and sulphuric acid industries. Installations in such plants in 1926 still outnumbered those in all other industries, and amounted to several hundred scattered throughout the world. Equipments at cement mills were fewer in number but handled a large volume of gas and a large tonnage of precipitate. Other important applications are to the detarring of coke-oven gases, the cleaning of producer and iron blast-furnace gas, the cleaning of ventilating air in crushing, grinding and polishing mills (especially where cost of heating in winter makes recirculation of air important), the recovery of sludge acid fumes in petroleum refineries, the recovery of dust from brown-coal dryers, and the removal of ash from the stack gases of large power-plants burning powdered coal. On a laboratory scale the process has also been applied successfully to sanitary atmospheric analysis and to gas masks, including the removal of bacteria from air, but suitable standard equipment for these small-scale uses is apparently not yet on the market.

The process in itself precipitates only suspended solid or liquid particles and makes no separation between gases. It has, however, an important indirect application to problems in this latter field, involving the recollecting of solid or liquid absorbents which have been dusted or sprayed into gas mixtures. The electrical demulsification or dehydration of crude petroleum and transformer oils, the separation of fine suspensions, such as clays in pure water and other poorly conducting liquids (electrical osmose or electrophoresis) and electrostatic concentration of ores, though dependent on some of the same natural phenomena, differ to such an extent, in principle and equipment required, from the process here described as to preclude their discussion under this heading.

FUNDAMENTALISM AND MODERNISM.—Fundamentalism is the name given to a religious movement which, appearing independently in different denominations in the United States during the period after the World War, steadily gathered momentum until in 1925 it became a subject of national, as distinct from denominational, interest through the trial and conviction of John T. Scopes, teacher of science in Rhea High School, Dayton, Tenn., on a charge of violating the Tennessee law prohibiting the teaching of evolution in the state public schools.

The trial began on July 10 1925, and was concluded on July 21 1925, by the conviction of the defendant and his sentence to pay a fine of $100. The immediate issue was as to whether the defendant had or had not violated the provisions of the state law as to the subjects to be taught in public schools, but the wider issue was as to the extent to which the state, in its control of public education, may determine the nature of the religious instruction given to the students in its schools. The trial itself was the culmination of a movement which had been going on for some years. Alarmed by the steady growth of liberal tendencies, the conservatives of the different churches had banded themselves together to stay what seemed to them the rising tide of negation. The form of the movement differed in the different communions according to the particular issue which was in question at the time, but common to all the Fundamentalist groups was, first, the acceptance of a view of the supernatural which insists that God manifests His presence in nature and history through exceptional and extraordinary activities, transcending the laws of nature; and secondly, the determination to use this conception of religion as a test to limit the freedom of teaching hitherto enjoyed by the ministers of the denomination. In all this there is nothing new. In every age conservatives and liberals have carried on their conflict over some form of this issue. What is new is the wide-spread character of the movement, the missionary enthusiasm which has been brought to it by its advocates and the consciousness on their part of interests transcending denominational lines and calling for a new alignment, with the Fundamentalists of all denominations on one side and the liberals on the other.

The Presbyterian Church.—In the Presbyterian Church the controversy centred about the case of Dr. Harry Emerson Fosdick, a Baptist clergyman who had been invited to act as stated supply for the First Presbyterian Church in New York City. Dr. Fosdick, who is also a professor in Union Theological Seminary in that city and a man of moderate liberal tendencies, made it his condition of accepting the call that he should be allowed to retain his membership in the Baptist Church. A sermon preached in May 1922, entitled "Shall the Fundamentalists Win?" was the occasion of an attack upon his theology by conservative Presbyterians, which led the General Assembly of 1923 to direct the Presbytery of New York to take such action as would require the preaching in the First Presbyterian Church to conform with the Confession of Faith. The Presbytery, after full conference with Dr. Fosdick and the Church, reported that such was now the case, whereupon the Assembly of 1924, without passing any judgment on Dr. Fosdick's theological views, expressed the opinion that if he were to remain longer in the pulpit of the Church, he should accept the standards of doctrine required of other ministers. On this issue Dr. Fosdick withdrew, declaring that "Creedal subscription to ancient confessions of faith is a practice dangerous to the welfare of the Church and to the integrity of the individual conscience."

In connection with this controversy the General Assembly in 1923 reasserted the so-called "Five Points," a declaration originally made in 1910, setting forth as essential doctrines of the Christian faith, the Virgin Birth, the physical Resurrection, the inerrancy of Scripture, the substitutionary Atonement and belief in the Miracles. In reliance upon this statement the judicial commission of the Assembly, in May 1925, declared that the Presbytery of New York had erred in licensing a student refused to affirm the Virgin Birth. The liberals attacked procedure as an unconstitutional limitation of the liberty interpretation accorded to every minister by the terms of scription, and to the Presbyteries by the historic precedents the Church. (*Cf.* Auburn Affirmation of May 1924, signed 1,283 members.)

The Baptist Church.—In the Baptist Church the controve has taken the form of an effort on the part of the conservati to secure the adoption by the Annual Conference of a creed wh should be used as a test of ministerial fellowship. This atten failed at repeated conferences, but the conservatives, defea at this point, have sought to secure their ends by instructi given to their Board of Home Missions as to the conditions to observed in the administration of their funds. One large beq was actually accepted by the board on conditions which see to some of its critics unduly to limit its freedom. A para effort to secure control over the teaching of the seminaries thus far failed of success.

Not the least important feature in the Fundamentalist mo ment is its bearing upon foreign missions. In general the poli of the different missionary boards has been to put the resp sibility for determining the doctrinal qualifications of candida upon the home church; and in the work on the foreign field c servatives and liberals have co-operated successfully in vari union enterprises. Fundamentalists have challenged this rangement and attacked the theology of liberal missionari On the whole this attack has been unsuccessful, and the un won on the field has thus far been maintained; but the battle by no means over or the danger at an end. A case in point is action of the General Convention of the Disciples at Oklaho City, Okla., on Oct. 6 1925, in reaffirming the principle of c communion which has been departed from by some of t missionaries in the interest of wider co-operation.

The Episcopal Church.—In the Episcopal Church the c troversy has centred about the literal observance of the cree On Oct. 5 1923 Bishop Lawrence of Massachusetts made address (afterwards published in pamphlet form) entitled *F Years*, in which he pleaded for a liberal interpretation of creeds. On Nov. 14 1923 at Dallas, Tex., the Bishops of Episcopal Church met this challenge by issuing a Pastoral sisting upon literal acceptance of the creeds and questioning good faith of those ministers who gave their historic stateme a symbolic interpretation. This Pastoral was attacked by liberals of the Church who were organised in a body known as Modern Churchman's Union. Sermons were preached by lead liberals, like Dr. Leighton Parks of St. Bartholomew's Churc New York, and Dr. William Russell Bowie of Grace Church the same city, and manifestoes were issued by theologians li the volume of essays entitled *Creeds and Loyalty* by seven me bers of the faculty of the Episcopal Theological School Cambridge, Mass. (1924). As a result of this agitation a tri for heresy begun against the Rev. Lee. W. Heaton for denying Virgin Birth was abandoned, and for the moment a truce has be declared.

The Bible Institutes.—One of the main sources of popul conservative propaganda is the so-called Bible institutes, which the most important are the Moody Bible Institute Chicago and the Bible Institute of Los Angeles. These school interdenominational in character, recruiting their scholars fro young people without college, and many of them without hig school education, insist upon the inerrancy of the Scriptur which they interpret commonly in the pre-millennarian sens They are carrying on an extensive propaganda partly throug periodicals of interdenominational character and partly throug conventions (the so-called prophetic conferences), which bri together large numbers of people. While not primarily designe as theological seminaries, many of their pupils are finding the way into the churches and are reinforcing the conservativ elements which are already there.

It is against the background of these influences that one mus interpret the Tennessee trial. Under the leadership of Willia nnings Bryan, the conservatives had been carrying on an ive campaign throughout the country, attacking the views of eral Christians as fundamentally irreligious and unchristian l insisting not only upon rigid measures on the part of the ividual churches, but also upon such a stiffening of the laws the states as to prevent what they regard as the insidious paganda of modernism in the schools. The storm-centre of debate was the doctrine of evolution which, as interpreted Mr. Bryan, involves a denial of the Biblical doctrine of ation and the surrender on the part of the teacher to an all-vouring materialism. In view of the fact that similar legislation either been passed or attempted in other states, it is not ely that a final decision will be reached upon this larger issue til the U.S. Supreme Court has passed judgment upon the tter. (W. A. B.)

FURNESS, HORACE HOWARD (1833–1912), American Shake-earian scholar (*see* 11.362c), died at Wallingford, Pa., Aug. 1912. His Variorum edition of *Cymbeline* was ready for the nter and appeared in 1913.

FUR TRADE (*see* 11.346).—The most important development this field in the period 1910–26 has been the rise of fur farming, de possible through the domestication of the silver fox and ner fur-bearing animals. This industry had its inception in ince Edward Island, Canada, those chiefly responsible for successful development there being R. J. Oulton, Charles ulton, J. S. Gordon, Robert Tuplin and B. J. and Silas Rayner. the silver fox pelt is the most valuable skin produced in orth America, these men were able to accumulate great alth for themselves as well as opening the door to similar portunities for others. Domesticated silver foxes sold at st for as high as $35,000 a pair. Prices have since fallen, with e stabilisation of the industry, to less than $1,000.

Development of the Industry—The Governments of Canada d of the United States have taken cognisance of the new dustry by the establishment of experimental ranches and formation bureaux. Yearly exhibitions also have been stituted for the comparison and judging of the animals. The dustry has since spread widely, ranches having been established Great Britain, Norway, Sweden, Germany, France and other untries. The domestication of the silver fox has encouraged nilar experiments with other animals and these have led to the ccessful rearing of minks, red foxes, blue foxes, raccoons, rakul sheep (persian lambs), martens and fishers. Muskrats d beavers have also been raised in confinement for the sake of eir pelts and require a much larger territory in which natural nditions are maintained and enemies excluded. Under such nditions these animals multiply very rapidly.

Markets and Production.—Prior to the World War London d Leipzig were the two largest fur markets in the world, more an half the total supply being sold at these places. Most of the essing and dyeing was done in Germany. It is estimated that 1910 North America and Europe each produced furs valued at $24,000,000, Asia $26,000,000, Australia $6,000,000, South America $2,000,000, and Africa and Oceania $2,000,000. The annual production has, since that time, more than doubled in value, Canada producing the greatest amount and exporting in 1925 pelts valued at $17,119,981 (about $22,000,000 in 1919–20). This increase is to be accounted for in large part by the rise in value of furs, occasioned in the first instance by the scarcity of pelts following the War. Muskrat pelts, the staple fur of North America, which had formerly been sold for from 10 to 30 cents apiece, frequently brought a price of $5.00. The interruption in trade caused by the War resulted also in the rise of a number of new fur markets, notably in St. Louis, New York and Montreal. The combined offerings of muskrat pelts at these three cities in the years 1920–3 amounted on the average to 3,366,516 pelts. The combined offerings of all auctions for these skins held in North America for 1924–5 averaged 4,594,446 pelts per year.

Manufacture in America.—Before 1914 approximately 65% of the furs secured in North America were exported abroad for manufacture and sale. The difficulties of export during the War, however, resulted in a large increase in fur manufacturing in America and particularly in the United States, where it is largely concentrated in New York City. The total imports into the United States from Canada and other countries in 1924 were valued at $87,705,582. About 20,000 concerns in the United States were handling furs in 1924. Of these, New York City alone had 2,000 wholesale manufacturers, who disposed of 80% of the manufactured furs sold in the wholesale trade. The fur-manufacturing establishments in the United States increased from 1,300 in 1914, employing 9,000 people, to 1,700 in 1923, with 19,000 employees. The wages paid increased from $6,000,000 in 1914 to $28,000,000 in 1923. The estimated retail value of furs and fur trimmings sold annually in the United States is $500,000,000.

FURTWÄNGLER, WILHELM (1886–), German conductor, was born in Berlin Jan. 25 1886, the son of the famous archaeologist and university professor, Adolf Furtwängler (1853–1907). He received his musical education in Munich from Beer-Walbrun, Rheinberger and Schillings, and then acted as conductor at Zürich. Later he occupied similar positions at Strasbourg, Lübeck, Mannheim, Vienna and Frankfort-on-Main. In 1922, on the death of Arthur Nikisch, he became director of the Berlin Philharmonic Orchestra and of the Gewandhaus concerts at Leipzig. Ranked among the finest conductors in Germany, Furtwängler also gained an international reputation, which was considerably enhanced by his annual concerts in New York.

GAELIC LITERATURE: *see* IRISH LITERATURE, GAELIC; SCOTTISH-GAELIC LITERATURE.

GAIRDNER, JAMES (1828–1912), British historian (*see* 11.390), died at Pinner, Middlesex, Nov. 4 1912. A third volume of his *Lollardy and the Reformation in England* appeared in 1911.

GALATZ or GALATI, Rumania (*see* 11.396), saw considerable industrial development before the World War. The population, 73,512 in 1914, was estimated in 1919 at 60,000. The export of grain and timber has revived, and there are grain- and flour-mills in the town. The port has been improved, and vessels of 5,000 tons can reach it since dredging on the Danube has been resumed; there is now from 20½ to 23 ft. at low water. The docks accommodate 10 steamers and 20 barges. The communications by road and rail, however, are unsatisfactory, and are liable to be interrupted altogether in winter. Galatz is the seat of the Rumanian naval school. The Rumanian naval base is at Sulina. (*See* DANUBE.)

GALE, ZONA (1874–), American author, was born at Portage, Wis., Aug. 26 1874. Having graduated from the University of Wisconsin, she engaged in newspaper work in Milwaukee, and in 1901 joined the staff of *The World* (New York). After 1904 she devoted herself to fiction, verse and plays, producing among other works, *The Loves of Pelleas and Ettarre* (1907); *Friendship Village Stories* (5 vol., 1908–19); *Birth* (1918); *Miss Lulu Bett* (1920); *The Secret Way*, verse (1921); and *Faint Perfume* (1923). She was awarded a Pulitzer Prize for her dramatisation of *Miss Lulu Bett*, produced in New York, 1920.

GALICIA, EAST (*see* GALICIA, 11.401), a district assigned to Poland in 1923. Its oil-fields are of great value. The province of Galicia, finally assigned to Austria in 1815, fell into two well-defined ethnographical parts. East of Przemysl, some 72% of the population was Ruthenian (Ukrainian), the minority being mainly composed of Poles and Jews, who are extraordinarily numerous in the towns. It was usually contended by the Poles of Galicia that Ruthenes do not exist; and the Austrian Govt. long accepted this theory in order to ensure the loyalty of the Poles. The Russian Govt. also supported this view in order to discourage the nationalist movement in the Ukraine; and the Ruthenes themselves were divided—one party feeling itself Russian, the other Ruthenian-Ukrainian. About 1910, when the Neo-Slav movement partly reconciled the Poles with the Russians, thus shaking their loyalty to Austria, Austria began to encourage the particularist Ruthenian movement as a counterblast to Panslavonic ideas.

During the War East Galicia was the scene of heavy and continuous fighting. During 1916–7, in view of the importance of Poland for the Central Powers, it was proposed to unite all Galicia with Russian Poland in a Kingdom of Poland more or less closely attached to Austria-Hungary. But after the collapse of Russia, the Central Powers concluded a peace with the Ukraine at Brest-Litovsk (Feb. 9 1918) and Austria-Hungary promised to erect East Galicia, with the Bukovina, into a separate Austrian territory (Kronland).

The Ruthenes Claim Independence.—While the claims of the Poles to autonomy were universally recognised, those of the Ruthenes were forgotten. In Oct. 1918 the Austrian Govt. having promised to introduce a federal system, the Polish leaders claimed for themselves all Galicia. The Ruthenes replied that they would rather "fight and die than let themselves be annexed by Poland." They summoned a conference of representatives of all Ruthenes of Austria-Hungary to meet at Lemberg (Lvov, Lwow, Léopol) on Oct. 18. The Socialist party pressed for immediate union with the Ukraine; but the bourgeois parties formed a National Council which determined to form an independent state, inviting the Polish and Jewish minorities to co-operate. On Nov. 1 the Council occupied the government buildings in Lemberg with the help of Ruthenian regiments, and assumed the government of East Galicia within its ethnographical limi The Poles refused their co-operation, and fighting began betwe Poles and Ruthenes. The Austrian Govt. recognised the Ruth nian Govt. which was now formed under Dr. Eugen Petrushiewic and handed him over a share of the old Imperial assets; but t Poles immediately invaded East Galicia, occupying Lemberg Nov. 5. The Ruthenian Govt. retired to Vienna, and its activ ties now became very platonic, being chiefly concerned wi propaganda, in which it developed prodigious activity.

Meanwhile on Jan. 3 1919 the Hetman Petlura, who at th time had established his authority in the Ukraine, proclaim the union of Russian Ukraine and West Ukraine (East Galici in a republic. The Ruthenian troops joined the Ukrainian Arn with the consent of the East Galician Govt., which recognise Petlura's authority on Jan. 20. Fighting continued throughou 1919, during which time Polish troops occupied East Galicia, in d fiance of the efforts of the Supreme Council to arrange a truce an settle the problem. On May 8 the Supreme Council assigned We Galicia to Poland; but on June 24 it decided to give East Galic the right of self-determination, although authorising Poland proceed with her military occupation of the district. The Eas Galician Govt. revoked its recognition of Ukrainian authorit on Aug. 28 1919, and continued to assert the legality of its ow position and the right of East Galicia to self-determination.

In Dec. 1919 the Allied and Associated Powers announce that East Galicia would be granted autonomy for 25 years unde a Polish protectorate, after which time the League of Nation would decide on its future. This remarkable arrangemen evoked vehement protests from the Ruthenes. It also caused crisis in Poland, which desired unconditional possession of th district, and resulted in the fall of Paderewski. Petrushiewicz' Govt. was, however, powerless, and the numerous Ukrainia governments which existed simultaneously or consecutively wer fully occupied in war with each other, the Poles, the Bolsheviks o the White Russians. In April 1920 Petlura abandoned his clai to East Galicia in return for recognition by Poland; Petlura' and the Polish armies captured Kiev from the Bolsheviks o May 8; but by Nov. the Bolsheviks had driven Petlura out o the Ukraine and established themselves there firmly. In Galicia however, the Poles held their own, and the Treaties of Riga Oct. 12 1920 and March 18 1921, re-established the old frontie of Galicia with the Ukraine.

Petrushiewicz's Govt. was in a disastrous position. It was ignored by everyone; its funds were running out; its choice o allies lay between its hereditary racial enemies, the Poles, and Bolshevik Ukraine. The Poles meanwhile treated the district as their own; held elections to the Polish Diet in it in the autumn of 1922—although practically the whole Ukrainian population abstained from voting—and even pressed Ruthenes into the Polish Army. On March 14 1923 the Conference of Ambassadors recognised Poland's *de facto* eastern, northern and southeastern frontier.

The Polish Régime.—Political activity in East Galicia di not lose its customary complexity after this date. Many poliical leaders, including Petrushiewicz, came to terms with the Soviet authorities. The great bulk of these unfortunates were unable to return to their homes. A small minority accepted the situation, and attempted to combine with the other racial minorities in Poland. A general law passed by the Polish Diet on Sept. 26 1922, which established local government bodies to deal with purely local affairs, contained the proviso that in the East Galician provinces these bodies should consist of two chambers, of which one should be Ruthenian. This "autonomy," as it was described, was to be introduced within two years; the language rights of minorities in Poland were to be respected, and colonisation forbidden. But in fact, although a language law was passed on July 10 1924, providing that Ukrainian, White Russian or Lithuanian should be the language of administration, w-courts and schools in districts where the majority of the pulation speaks one of these languages, and Count Skrzynski owed a not illiberal attitude towards the minorities generally, olish policy in general was not hampered by an excess of scruples wards the Ruthenes. (C. A. M.)

GALLI-CURCI, AMELITA (1889–), Italo-American singer, as born at Milan, Italy, Nov. 18 1889. As a vocalist she was lf-taught. Gifted with a singularly pure soprano voice, she ade her début as Gilda in *Rigoletto* at the Constanzi Theatre, ome, in 1909, and subsequently visited Spain and South Amera. She made her first appearance in the United States at the uditorium, Chicago, Nov. 18 1916, where she remained four asons. She was engaged by the Metropolitan Opera Company, ew York, in 1921 and from that date constantly appeared in rand opera and concerts. Among her chief rôles were Buttery, Juliette, Lucia, Mimi, Rosine, Violetta and Manon Lescaut. he made a concert tour through Great Britain in 1924–5.

GALLIÉNI, JOSEPH SIMON (1849–1916), French general and atesman (*see* 11.418), reached the age limit for retirement on pril 24 1914, but was retained on the active list without duty, nd on July 31 1914 was officially confirmed as the eventual successor of the commander-in-chief. On Aug. 26 he was appointed overnor of Paris and general commanding the armies of Paris. Ie took energetic steps for the defence of the capital, and on ept. 3 issued the following order: "To the Army of Paris and he Population of Paris: The Members of the Government of he Republic have left Paris in order to give a new impulse to ational defence. I have been ordered to defend Paris against he invader. This order I shall fulfil to the end."

After Sept. 2 the armed forces in Paris had been placed under he orders of Joffre, who could thus in case of need use the garison for his operations; consequently, on Sept. 3 Galliéni wrote o Joffre asking for instructions. From information received luring the day, however, Galliéni concluded that the German orces marching on Paris were inclined southeast, thus offering im an exposed flank. Joffre's answer to Galliéni's messages rrived on the 4th a little before 3 P.M. and contemplated an ttack south of the Marne. Galliéni held that to gain the fullest ossible advantage from the situation by enveloping Von Kluck nd breaking his lines of communication the attack ought to be nade on the line of the Ourcq north of the Marne, and made at nce. Galliéni spoke to Joffre on the telephone on the 4th at ; P.M. and obtained authority to move on the 5th north of the Marne for the attack on the 6th. The VI. Army under Maunoury vas placed under Galliéni's command. Maunoury was given all he troops available and ordered to move on the 5th to the eights of the Ourcq, to attack on the 6th. But, while executing his movement, Maunoury was himself attacked on the 5th y the German IV. Reserve Corps, which covered Von Kluck. The two armies were almost equal; six divisions against six. But luring the night of the 7th–8th Galliéni sent up the 7th division in taxis from Paris to Nanteuil-le-Haudouin. The Germans retreated and the French armies moved out of the zone over which Galliéni held command.

On Oct. 29 1915 Galliéni became Minister of War in Briand's Cabinet. His period of office was made notable by endeavours to create unity of command and by changes in the position of Gen. Joffre. He resigned for reasons of ill-health on March 16 1916 and died at Versailles, after undergoing two operations, on May 27. His body was given a state funeral, and lay for a time under the dome of the Invalides. He was buried at St. Raphael. On April 21 1921 the dignity of marshal of France was conferred on him posthumously.

GALLIPOLI: *see* DARDANELLES CAMPAIGN.

GALSWORTHY, JOHN (1867–), British playwright and novelist, was born at Coombe, Surrey, Aug. 14 1867. Educated at Harrow and New College, Oxford, he was called to the bar in 1890, but devoted himself to literature. His first novel, *Jocelyn*, appeared in 1898, but he attracted wider attention in 1904 with *The Island Pharisees*, and *The Man of Property* (1906). The latter was the first novel of the sequence to be known later as *The Forsyte Saga*, the others being *The Indian Summer of a Forsyte* (1918); *In Chancery* (1920); *Awakening* (1920); and *To Let* (1921). As a detailed picture of upper middle-class society during the later Victorian and Edwardian eras, the sequence is a remarkable achievement. That picture was supplemented by the greater number of Galsworthy's other novels, of which it is the characteristic social setting, among them *The Country House* (1907); *Fraternity* (1909); *The Patrician* (1911); *The Freelands* (1915); *The White Monkey* (1924). Galsworthy also wrote *The Dark Flower*, 1913, and many short stories, of varying merit, but often worthy of his best work, collected as *Caravan* (1925), essays on current social and moral questions, marked by liberal and humane feeling, and a commentary on the extravagances of war time, *The Burning Spear*.

As a dramatist also, Galsworthy enjoyed a deserved fame. His plays, for the most part, are based on ethical or social problems and are marked by a scrupulously judicial fairness in displaying the opposing points of view typified by his characters. Some have partaken too much of this scrupulousness to be counted as having an essentially dramatic quality, but at their best Galsworthy's plays reflect not only his finest powers as a literary craftsman—for their diction is natural and serious without becoming loose or facile—but also a keen sense of dramatic values. Among them should be noted *The Silver Box* (1906); *Joy* (1907); *Strife* (1909); *Justice* (1910); *The Pigeon* (1912); *The Eldest Son* (1912); *The Fugitive* (1913); *The Skin Game* (1920); *Loyalties* (1922); *The Forest* (1924).

See S. Kaye-Smith, *John Galsworthy* (1916); André Chevrillon, *Trois Études Anglaises* (1924).

GALTON, SIR FRANCIS (1822–1911), British anthropologist (*see* 11.427), died at Haslemere Jan. 17 1911.

GALVANAUSKAS, ERNEST (1882–), Lithuanian statesman, was born Nov. 7 1882 at Vabalninkai. He studied as a mining engineer at Leningrad (St. Petersburg) and Liége, and his activities in the Lithuanian national movement date from his student days. In 1906 he was imprisoned for his attempts to free the country from the Russian yoke. He escaped to Belgium in 1908, where he continued in touch with the Lithuanian liberation movement. The outbreak of the World War found him in Belgrade, and after the enemy occupation of that city, Galvanauskas left with the Serbian Army and shared all the privations of the retreat. He subsequently proceeded to France and volunteered for military service. On the recovery of Lithuanian independence in 1918, Galvanauskas served as a member of the Lithuanian Delegation to the Versailles Peace Conference. He was several times Prime Minister and Minister for Foreign Affairs, and also held the portfolios of Finance and Communications. He became president of the Lithuanian Delegation to the League of Nations and in Aug. 1924 was appointed Lithuania's first envoy extraordinary and minister plenipotentiary to London and simultaneously envoy extraordinary and minister plenipotentiary to The Hague. In Nov. 1925, for services to the Serbian cause in the World War, he received from the King of Yugoslavia, the high military order "Albarrakom Spozeincom."

GAMBIA (*see* 11.437a), a British colony and protectorate in West Africa. Its population was 210,530 in 1921, an increase of 60,000 in 10 years. Bathurst, the capital, had 9,227 inhabitants, of whom Europeans numbered 265 (130 British). Hemmed in landward by French territories, which make but little use of its magnificent waterway, Gambia depends upon its own resources.

The cultivation of the ground nut, entirely a native industry, is the chief occupation of the people. Up to 1915 the nuts (the oil from which is a main ingredient of margarine) went mostly to France, which in 1914 took 78% of the crop. Changes caused by the World War led to over 91% of the export going to England in 1919. France subsequently in part recovered the market. In 1924 England took 54% and France 33% of the crop, which represented some 95% of the total exports. The economic crisis caused by the War was safely weathered and 1920 was a year of trade activity. Imports are mostly cotton piece goods, rice and sugar and, from Sierra Leone, kola nuts. Great Britain's share of the imports averaged over 50% in the years 1914–24; France, Germany (since 1920) and the United States supply most of the other imports. In 1922 it became necessary to demonetise the French five franc piece, the favourite coin of the natives, and this involved the administration in a loss of £187,000.

Taking 1914 and 1924 as normal years the revenue rose from £86,000 to £208,000, the expenditure from £120,000 to £203,000. The tonnage of shipping entered and cleared was 1,100,000 in 1924 compared with 571,000 in 1914. British shipping predominated, but from 1921 Germany became a keen competitor and in 1924 was second, with 158,000 tons as against 643,000 British, 93,000 American and 92,000 French. Since 1901 Gambia has enjoyed political tranquillity, and education and Christianity made progress, if slowly. Most of the natives are Moslems. The Gambia Co. of the West African Frontier Force served with credit in the campaigns in the Cameroons and German East Africa. Bathurst was the first place visited by the Prince of Wales in his 1925 tour.

Bibliography.—H. F. Reeve, *The Gambia* (1912), an excellent monograph by a retired official; Sir G. Denton, "Twenty-three Years in Lagos and the Gambia," *Jour. African Society*, vol. 11 (1912); *The Gambia* (1920), a British Foreign Office handbook, and the annual reports issued by the Colonial Office, London.

GAME PRESERVES: *see* NATIONAL PARKS.

GANDHI, MOHANDAS KARAMCHAND (1869–), Hindu nationalist leader, was born at Porbandar (Kathiawar, India) of a Bania family with official traditions. At the age of 19 he went to London, studied for a time at University College, and was called to the bar by the Inner Temple. Soon after starting practice in the Bombay High Court he was called, in 1893, on professional business, to South Africa, where he threw himself at once into a long and bitter struggle for the liberties of the Indian settlers in that country. He became leader of the opposition to a variety of measures taken by the local authorities to discourage Asiatic immigration and to limit the rights of citizenship available to Asiatics already resident.

It was in the course of this movement that his conception of resistance without violence developed; he relinquished his large income as an advocate, and founded a colony for his compatriots on Tolstoian lines near Durban. As the price he paid for his championship of the Indians' grievances, besides being more than once arrested and imprisoned he suffered frequent indignities at the hands of angry mobs. This neither checked his energies nor deterred him from rendering service of marked loyalty to the Government on three occasions; for he raised and commanded a Red Cross unit in the Boer War, he organised a plague hospital when the epidemic broke out in Johannesburg, and he led a stretcher-bearer party in the suppression of the Natal revolt of 1908. At last in 1914 a commission of inquiry into the Indian discontent recommended the removal of several of the worst injustices against which Gandhi had striven; and he felt justified in closing down his activities in South Africa and returning to India. There a wider field of political protest awaited him; and he was soon at work organising, in connection with the home-rule movement, resistance to the British Government by "soul force" and nonco-operation.

In Jan. 1919 there were published two bills (subsequently known as the Rowlatt Acts) giving the Government emergency powers for dealing with revolutionary crimes and conspiracies; these had followed the proposals of a responsible commission which had investigated the subject, and the powers they conferred were safeguarded by elaborate protections against abuse. But Gandhi declared them to be an insult, intended to discredit the Indian people on the eve of ostensible political reforms, and he denounced the bills as instruments of oppression. He instituted a campaign of Satyagraha (literally, insistance on truth) or nonviolent disobedience to unjust laws in the first instance, enlarging if necessary into disobedience to any law and complete nonco-operation with the Government. Spreading rapidly, the agitation burst into violence in the Punjab and elsewhere, with results which shocked Gandhi into a temporary suspension of his civil disobedience. Later in the year, he formed common cause with the Indian Moslems of the Khilāfat party, aggrieved by the terms of peace which Great Britain was offering t Turkey; and in July 1920 he proclaimed a general campaign "non-violent nonco-operation." Its points were the bo cott of Government service, of the new legislatures and of th courts of law; the surrender of all public offices; and the wit drawal of children from Government schools; to which we subsequently added boycott of foreign goods and the adoptio of the spinning-wheel as an emblem of economic independenc

The agitation spread rapidly. The unlettered people w saw his earnestness and asceticism, and heard his simple el quence, regarded him as a saint, and invested him with the tit of Mahatma, or Great Soul. By 1921 Gandhi was at the zeni of his power. The national congress, sitting at Christmas that year, delegated its full authority to him, and empower him to appoint his own successor. But signs of change were no appearing. The unrest into which the non-co-operation mov ment had plunged the country culminated in a series of gra outrages, some of a racial character, of which the Mopla outbreak was the worst, and others directed against the agenci of law and order. Gandhi met them by personal penances, an by repeated postponements of the date on which he had for told that India would be liberated from British rule. But h had generated forces which he had no power to recall or contro and plain people were getting alarmed at the consequence Moslem support was being deflected from him by the encou agement which Lord Reading's Government was giving t Islamic sentiment over Turkey; and his closest adherents we embarrassed by his frequent changes of policy. Consequentl when he was arrested in March 1922 and put on trial for co spiring to spread disaffection with a view to overthrowing th government of the country, the *coup* evoked little excitemen Gandhi pleaded guilty, accepted responsibility for all that ha happened and invited "the highest penalty that can be i flicted upon me for what in law is a deliberate crime and wha appears to me to be the highest duty of a citizen."

Condemned to six years' simple imprisonment, he was re leased in Jan 1924 after an operation in gaol for appendiciti and the rest of his sentence was unconditionally remitted. H came back to a party which had chosen other leaders, and wa soon to reverse his policy of boycotting the administration Esteemed and consulted though he continued to be by his ol followers, he was no longer a power to sway the masses, and a the end of 1925 he announced his intentions of retiring from th world for a year. The nationalist movement was switched o to lines more familiar to western constitutional usage. To th Oriental mind Gandhi symbolised self-sacrifice and high ideal ism; western enthusiasts were not wanting who, like M. Romai Rolland, compared him with the Founder of Christianity; an the transparency of his character commanded the persona liking of even strong opponents. But he expected too much o human nature, he played recklessly with inflammable material his economic nostrums were unpractical and he gave way t unexpected bursts of intolerance, as when he described th British government of India as "satanic." His endeavour t unite Hindus and Moslems lacked sincerity; but his endurin legacy to Indian politics will be the part he has taken in consolidating Hindu nationalism.

GARDEN, MARY (1877–), American operatic singer, was born at Aberdeen, Scotland, Feb. 20 1877. At the age of six sh was brought to the United States. In 1888 her family settled i Chicago, where her early musical training was received. She went to Paris in 1896, and studied under Trabadello, Chevallie and Fougère. She made her début at the Opéra Comique, Paris April 3 1900 in the title rôle of *Louise*, taking the place, at a few days' notice, of Mlle. Riotou, who had fallen ill. Her first appearance in the United States was at New York in the title rôle o *Thais* Nov. 25 1907. In 1910 she became a member of the Chicago Grand Opera Company, assuming, among others, the parts of Salome, Thais, Mélisande and Louise. She was appointed general director of the Chicago Opera Association Jan 13 1921.

GARDEN CITY: *see* CITY PLANNING.

GARIBALDI, GIUSEPPE (1879–), Italian general, eldest m of Gen. Ricciotti Garibaldi and grandson of the Liberator, as born at Melbourne July 29 1879. He fought under his father . the Greco-Turkish War in 1897, and served in the South frican War, subsequently leading an adventurous life in outh and Central America and in the Balkans. On the outreak of the World War he raised an Italian Legion of 14,000 ien, which fought on the side of France in the Argonne. In 15 Garibaldi returned to Italy, and on Italy's entry into the Var he enlisted as a volunteer. He was soon afterwards comissioned, being given command of a battalion, and served with istinction in the IV. Army. He returned to the French front in Iarch 1918 in command of the famous Brigata Alpi, and in une was promoted brigadier-general. He resigned his command June 1919 and gave up his commission in Feb. 1920. He beame opposed to the Fascist Govt. and in the autumn of 1924 as involved in an anti-Fascist agitation organised by the *Italia bera* Association. Deciding, however, that the movement had o chance of success, he departed for New York to devote himself o business.

GARLAND, HAMLIN (1860–), American writer, was born t West Salem, Wis., Sept 16 1860. He graduated from the Cedar Valley Seminary, Osage, Ia., at the age of 21. After teaching in Illinois and taking up a claim in South Dakota (then Dakota territory), he went to Boston in 1884 and engaged in terary work. The drudgery of farm life in the Middle West and he adventurous life of the mountains furnished him with abunant material for his realistic tales. His works, all based on the fe of the northwest states, include *Main Travelled Roads* (1890–); *Ulysses S. Grant: His Life and Character* (1898); *Boy Life on he Prairie* (1907); *The Long Trail* (1907); *Money Magic* (1907); *Cavanagh* (1909); *Other Main Travelled Roads* (1913); *The Tyranny of the Dark* (1905); *A Son of the Middle Border* (1917); *A Daughter of the Middle Border* (1921); *The Book of the American ndian* (1923). He was made a member of the American Academy f Arts and Letters in 1918.

GARSTIN, SIR WILLIAM EDMUND (1849–1925), British engineer, was born in India Jan. 29 1849. He was educated at Cheltenham and King's College, London, and in 1872 entered he Indian Public Works Department. In 1885 he was transferred o Egypt and in 1892 became inspector-general of irrigation and Under-secretary of State for Public Works. He proved himself an indefatigable worker, and by his efforts extensive areas were reclaimed in Egypt and the Sudan. Among his greatest works were the Asyut barrage and the Aswan reservoir. In addition, it was due to him that the White Nile was cleared of sudd, thus rendering possible free navigation between Khartoum and Gondokoro. He was created K.C.M.G. in 1897 and G.C.M.G. n 1902. In 1907 he was appointed British Govt. director of the Suez Canal Company. During the World War he devoted himself to Red Cross Work in England, being created G.B.E. in 1918. He died in London Jan. 8 1925.

GARVIN, JAMES LOUIS (1868–), British publicist, and editor-in-chief of the present volumes of *The Encyclopædia Britannica*, was born at Birkenhead, Ches., April 12 1868. A political writer from the age of 17, he joined *The Newcastle Chronicle*, where from 1891 to 1899 he was leader-writer, literary critic and aide-de-camp to its proprietor, the celebrated orator, Joseph Cowen. From the age of 26 for many years he was a chief contributor to *The Fortnightly Review*, and later to *The National Review* and *The Quarterly*. In 1899 he went to London, joining the staff of *The Daily Telegraph*, which gave him unusual scope. When Mr. Joseph Chamberlain started his historic campaign for tariff reform and Imperial unity, Mr. Garvin became nationally known as that statesman's most powerful lieutenant in the Press. Editor in 1905–6 of the weekly review *The Outlook*, he passed in 1908 to the editorial chair of *The Observer*. He raised that oldest of great Sunday journals to the highest position it had ever reached, and made it quoted throughout the world. Simultaneously from 1912 to 1915 his editorship gave new life to the evening *Pall Mall Gazette*. Steeped in German studies, his articles on foreign affairs, anticipating the World War from as early as 1901, had a deep public influence. In the War his articles were famous; but, equally the advocate of "absolute victory" and a wise peace, he was a searching and damaging critic of the Treaty of Versailles. To promote international reconciliation and co-operation he wrote in six weeks during the Paris conference (1919) his elaborate book *The Economic Foundations of Peace*. His only son, Gerard, who had justified high hopes, was killed at the age of 20 in the battle of the Somme, gallantly leading two companies of the South Lancashire Regiment in a night action. Behind all Mr. Garvin's politics there is a deep background of history and literature. In 1926 he was chosen chairman of the Empire Press Union.

GARY, ELBERT HENRY (1846–), American jurist and business man, was born near Wheaton, Ill., Oct. 8 1846. He attended Wheaton College and then, after studying law for a time in an office, he continued his legal studies at the University of Chicago, and took the degree of LL.B. in 1867. In 1871 he began practice in Chicago, where he became a noted corporation lawyer. In 1874 he organised the Gary-Wheaton Bank, of which he was president. He was elected judge of Du Page Co. in 1882 and again in 1886; was three times elected president of the town of Wheaton, and on its becoming a city in 1892 served as mayor for two terms. He was president of the Chicago Bar Association 1893–4. He early saw the advantages of combination in business and in 1891 was one of the organisers of the Consolidated Steel & Wire Co. In 1898, upon the organisation of the Federal Steel Corporation, with a capital stock of $200,000,000, he became its head and retired from legal practice. This company was merged in the United States Steel Corporation in 1901 with a capital stock exceeding $1,000,000,000 and he was elected chairman of the board of directors and of the finance committee. He continues to fill these offices after twenty-five years of remarkable development of the steel industry, and growth of the corporation. The town of Gary, Ind., laid out in 1906 as a model home for steel workmen, was named in his honour. In 1914 he was made chairman of the committee appointed by Mr. Mitchel, mayor of New York, to study the question of unemployment and its relief.

When America entered the World War in 1917, Gary was appointed chairman of the committee on steel of the council of national defence. Through his own connection with a business essential for munitions of war he exerted great influence in bringing about co-operation between the Government and industry. He was interested in a strengthening the friendship between America and Japan. In 1919 he was invited by President Wilson to attend the Industrial Conference in Washington, and took a prominent part in it as a firm upholder of the "open shop," of which he was always a strong advocate. He also opposed the drastic restriction of immigration effected by the "Quota" law. Miss Ida M. Tarbell's *Life of Judge Gary* concludes with these words: "He has made a lasting contribution to our difficult and often baffling problem of substituting, in American business, balance for instability, mutual interest for militarism, co-operation for defiance, frankness for secrecy, goodwill for distrust. No man in contemporary affairs has more honestly earned the high title of industrial statesman."

GARY, Ind., U.S.A. (*see* 11.480), had become in 1920 a city with 55,378 inhabitants of whom 5,299 were negroes and 16,460 foreign-born. In 1925, the 20th year of its existence, its population was 81,888 (school census); it had an area of 40·83 sq. m., 155·35 m. of improved and 178·45 m. of unimproved streets, 15 m. of boulevards, 45 m. of street railway track, a fleet of motor-buses and 94 m. of water-mains. The assessed valuation of taxable property was $131,006,810. There were over 1,000 retail stores. During the nation-wide strike of the steel workers in 1919, Gary was occupied by Federal troops from Oct. 7 until the strike was called off on Jan. 7 1920. A city-planning commission was appointed in 1919 and a comprehensive zoning ordinance was adopted in 1925. The "Gary Gateway and Railway Developement," which was adopted in 1924, provided for improved freight and passenger facilities and for beautifying a large section.

The public schools of Gary offer academic instruction 48 weeks in the year and physical training for 52 weeks of 6½ days each week. The first superintendent of schools, William A. Wirt, worked out a system with the following features: (1) an enriched curriculum; (2) a school plant adapted to such curriculum, with playground, gymnasium, swimming-pool, shops, laboratories and auditorium; and (3) organisation of classes on a "platoon" system, by which each feature of the plant is in use all the time, thus providing for the most economical utilisation of both plant and teaching force. This administrative scheme (3) became known among educators as the "Gary Plan" and was adopted, with more or less modification, in many cities.

See F. P. Bachman and R. Bowman, *The Gary Public Schools*, a Study by the General Education Board in eight parts (New York, 1918).

GAS IN WARFARE: *see* CHEMICAL WARFARE.

GAS, MANUFACTURE OF (*see* 11.483)—In the period 1910–25 the work done on gas retorts, coke ovens, gas generators, the complete gasification of coal, low temperature carbonisation and other operations in the gas industry has been considerable. During the War, gas-retort and coke-oven plants were worked to their full capacity; repairs and renewals were often unavoidably deferred or effected under difficult conditions. Gas and coke manufacturers have studied nearly every branch of the industry, and therefore many important changes have taken place.

Therms.—In Great Britain the provisions of the Gas Regulation Act of 1920 impose an obligation on the suppliers to charge for gas at a price based on the calorific value of the gas and specified the use of a recording calorimeter for determining this value. The calorific unit selected, the therm, is equal to 100,000 B.T.U.'s or British Thermal Units. Each gas undertaking formally declares the calorific value of the gas it proposes to supply; this is called its "declared calorific value" and is usually from 450 to 500 B.T.U.'s per cubic foot of gas.

The method of reading the gas meter remains the same, but the gas account is made out in therms at so much per therm. The number of therms is easily computed, for, suppose that the meter readings show that 10,800 cu. ft. of gas have been supplied and that 500 is the declared calorific value, then 10,800×500÷100,000=54 therms. At tenpence per therm, the gas bill would be £2·5·0.

The Act allows a gas undertaking to declare any calorific value it chooses. Therefore, subject to the requirements of gas purification, the company is free to adopt gas-making processes which will yield the maximum number of therms for every ton of coal treated. Clearly, it may be most profitable to supply a mixed gas, or to leave in the gas constituents which, like benzol, have a high thermal value; with gas and benzol at their present prices, benzol is usually left in the gas.

Calorimeters.—Among the recording calorimeters used by gas undertakings are the Simmance Total Heat, the Fairweather, and the Boys, in all of which the heat of combustion of known quantities of gas to be tested is imparted to a flow of water; the Thomas, in which the heat is imparted to air; and the Beasley, in which a differential thermometer filled with oil is employed. At large gasworks, several calorimeters are used, one in connection with the town's gas supply and the others with the separate gas-making plants.

Refractory Materials.—In Great Britain, siliceous clays containing 80 to 92% of silica and silica clays with more than 92% of silica have been used to an increasing extent in the gas industry and carborundum has also been tried. For the hotter parts of vertical retorts, siliceous and silica clays are commonly used and silica clays have been employed largely in constructing the coke-oven plant of the Consett Iron Co., Ltd., and other companies. In America the use of silica clays is the standard practice, not only for the hotter parts of vertical retorts and for the chamber ovens of the Koppers and other types for supplying gas, but also for horizontal retorts.

Silica bricks are more fragile, and have a coefficient of expansion greater than that of firebricks. Their greater heat conductivity facilitates rapid carbonisation; they sustain high temperatures and keep their shape in a satisfactory way. It is probable that the life of silica is greater than that of fireclay retorts a ovens. At St. Helens, eight Glover-West retorts, in which Frid silica was used, had an average working life of 1,694 days. Son of the American chamber ovens, constructed by Messrs. Ko pers, have worked continuously for 15 years and are said not have needed repairs (*see* ELECTRO-METALLURGY).

Carborundum is very refractory, hard and strong; its coef cient of expansion is very small; its heat conductivity is abou five times that of fireclay. The future of this valuable refracto material will depend largely on its initial cost, and on its beha iour in an oxidising atmosphere at high temperatures. Willian son, Cliff, Ltd., of Stamford, have constructed a horizont retort with a tile of carborundum extending along the centr part of the retort sole. In the United States, carborundum ha been used in both retort and gas generator construction.

The Retort Controversy.—The question of the best type of ga retort has been decided to a large extent by the selections mad by numerous gas engineers when erecting new installations of retorts. There are installations of inclined retorts working satisfactorily and numerous installations of horizontal retorts provided with efficient charging and discharging machines, but the tendency is clearly in the direction of using continuously operated vertical retorts.

Horizontal Retorts.—The improvements made since 1910 in these retorts and their settings have been mainly in details. Some continuously operated horizontal retorts erected by West's Gas Improvement Co., Ltd., at Blackpool and Middleton, did not show any advantages over the Glover-West vertical retort, and were abandoned.

Vertical Retorts.—The chief improvements in vertical retorts have been in connection with those of the continuously operated type, in which coal is fed into the top of the retort and coke discharged from the bottom in a continuous and regular manner, the retort increasing in area downward to facilitate descent of the charge. The Glover-West and the Woodall-Duckham vertical retorts are the chief examples.

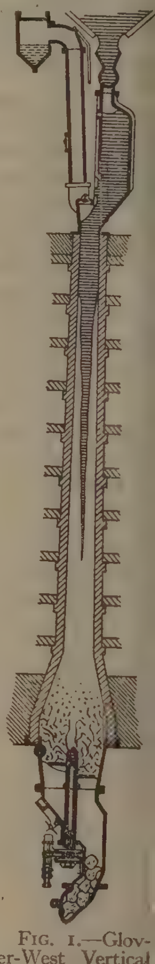

FIG. 1.—Glover-West Vertical Retort.

The Glover-West continuous vertical retort was originally developed on principles deduced from the practice with Scotch shale retorts. In its most approved form, the 40-in. new model, the cross-section is a flattened ellipse, the major axis of the mean section being 40 inches. Vertically, the retort enlarges regularly until the steaming chamber or "bell-bottom," clearly shown in fig. 1, is reached. This chamber opens up the core of coke and permits the exposure of a large surface of coke to the action of steam injected for making water gas. A powerful helix mounted on a vertical shaft, shown in fig. 1, supports the full weight of the coke; it is driven by worm gearing and, as it revolves, the coke is lowered continuously and regularly into the coke chamber, with a minimum of breakage. A step-grate producer generates gas which is led to combustion chambers arranged horizontally across the lines of retorts. The temperature distribution can be readily varied over the whole length, about 25 ft., of the retort, according to the carbonisation requirements of the coal treated. The Glover-West was successfully worked at the St. Helens gasworks in 1909. Since then, more than 135 gas undertakings in all parts of the world have adopted it; the new model has been installed recently at Oldbury, Nine Elms (Gas Light and Coke Co.), Dudley Leicester, Toronto and Malden, United States of America.

In the Woodall-Duckham continuous vertical retort the ntinuous and regular discharge of the coke is effected by an tractor roller formed of a series of stars set on a horizontal aft slightly in advance of each other, so as to form helical ades. The shaft is mounted in a gas-tight hopper, having one de curved so as not to prevent descent of the coke by gravita- on while supporting the greater part of its weight.

Heating of the retort is effected by means of a regenerative s producer. There are two very hot combustion chambers, ne at the top of the retort and another lower down for ensuring at the charge is hot enough for obtaining good water gas by e action of steam admitted to the retort. The Woodall- uckham retorts were installed at the Bournemouth gasworks, 03 -5; since then, numerous installations have been set up in l parts of the world. Among the most recent are those at Dun- rmline, Glasgow, Edinburgh, Warrington and Bergen.

Coke Ovens.—The course of development in coke-oven practice is been chiefly in the utilisation of surplus gas for town supply, nd in the installation of very large ovens of known types. Great Britain parliamentary sanction was first given in 1910 r the supply of coke-oven gas. The Board of Trade returns r 1924 gave 16 towns taking gas from colliery and other coke- ven plants, Chesterfield, Sheffield, Leeds, Middlesborough and ontypridd being included. Most coke ovens in Great Britain not take a charge exceeding 8 tons, but ovens of the Piette pe, of nearly 18 tons capacity, have been built at Stoke-on- rent by the Semet-Solvay and Piette Co. of Sheffield. In the nited States, it is common practice to use coke ovens of about tons capacity.

Charging and Discharging.—The introduction during recent years efficient charging and discharging apparatus has done much to able horizontal retorts to compete with other types of retort. any charging machines, *e.g.*, the Arrol-Foulis hydraulic charger d the de Brouwer, which projects the coal into the retort, are orked in association with a separate discharger. Drake's projector d pusher is a combination of a pusher made up of large, jointed ctions, adapted to fold over a rotary, polygonal drum and a rapidly tating wheel with vanes for projecting coal into the retort; the isher discharges the retort and is withdrawn, and then the pro- tor comes into operation. A further development is a type of paratus called a discharging charger, of which Guest and Gibbons' scharging charger is an example; it is described in British Patent ecification No. 103143/1916. A sectional, jointed trough which, it travels forward from its supporting wheel, discharges the coke, s mounted within it rollers supporting and guiding an endless drag- r chain. During the withdrawal of the trough, this chain is driven dependently and carries coal into the retort so as to fill it com- etely.

Steaming Practice.—Steam has been used, especially in the essau intermittent retorts, to increase the yield of ammonia. uring recent years, however, the practice has been greatly ex- nded, especially in working continuous vertical retorts, which are lmirably adapted for steaming. The method admits of numerous sy variations; usually superheated steam under a pressure of 10 40 lb. per sq. in. through a $\frac{1}{8}$-in. nozzle. As long as the steaming is t excessive, it increases the yield of gas, ammonia (*q.v.*) and tar, d also the total thermal yield, although the calorific value per . ft. of gas is lowered.

Coal Blending.—The blending of different kinds of coal has long en practised, especially in America, to obtain suitable charges for e in coke ovens. Coal blending has recently attracted attention, pecially in connection with smokeless fuel production. It has been oposed to mix several kinds of coal so as to obtain a blend having predetermined resinic content or yielding a predetermined amount volatile matter when heated. By this blending, it is sought to inimise the expansion of the coal when carbonised at low tem- erature, to facilitate discharge by preventing the coke from sticking the retort, and to obtain a coke of good quality. Processes of this nd are described in British Patent Specifications Nos. 164104 and 6085 (Illingworth) and 187336 (Roberts).

Coal Cleaning.—The removal of clay, shale, pyrites and other purities from coal by washing processes is important, especially in eparing charges for ovens used in making metallurgical coke, and connection with smokeless fuel production to facilitate the making a good quality fuel. The catalytic action of some of the inorganic nstituents during carbonising processes, is also receiving attention.

Carburetted Water Gas.—During recent years, increasing quan- ties of water gas, especially carburetted water gas, have been ade in Great Britain. In America, more than one-half of the s manufactured is carburetted water gas; Philadelphia is sup- ied almost entirely with this gas.

In the self-clinkering, self-steaming generator of Humphreys and Glasgow, Ltd., an annular water jacket forms the lower part of the generator and supports an upper firebrick part; the jacket is high enough to prevent adhesion of clinkers to the generator wall. A steam reservoir communicates with the jacket by pipes, and serves as a source of steam supply for the generator. A mechanically operated grate, having an upper conical part, formed with air passages, and a lower cylindrical part, is mounted eccentrically on the base of a rotary water pan. A central conduit conducts the air blast or steam or carries away the down-run gas, when the run is downward, for the run may be upward or downward as desired. During its rotation, the grate crushes and expels the clinker and ash, the carbon content of which has been reduced as much as possible. The speed of the grate is regulated automatically; this regulation may be effected by electric means, the action of which is controlled by the temperature beneath the grate. When carburetted water gas is to be produced, the gas is led from the generator to a carburettor supplied with a spray of heavy oil and thence to a super-heater in which the cracked oil-vapour is fixed.

Many of these generators are working in association with batteries of horizontal or vertical retorts, the whole representing a very advanced development of gas-making plant. The coke from the retorts, in a cold, clean state, is charged into the producers and the operation of the whole installation effects a substantially complete gasification of the coal. The loss of heat of the incandescent coke is of comparatively small importance, for the clean, cold coke is rapidly brought to an incandescent state in the generator and there is no expensive handling of hot coke. A self-steaming, self-contained, blue water-gas plant, erected by Humphreys and Glasgow, Ltd., comprises (*a*) a generator, (*b*) a recuperator, (*c*) a waste-heat boiler and (*d*) a washer-scrubber (see fig. 2). This firm has brought into commercial use a means for automatically operating a generator plant, in which a series of valves governing the interdependent operations necessary in working, *e.g.*, coke feed, air supply, steam supply, duration of blow, etc., is operated by hydraulic power in an order correct in time and sequence. The order of operation, determined by the conditions of temperature, pressure, etc., in, or connected with, the generator, is set once for all by adjusting the indicators of a series of dials corresponding respectively with the various valves. If any valve fails to respond in its turn, the cycle of operations is stopped automatically by the action of electric circuits; this prevents explosions or other accidents.

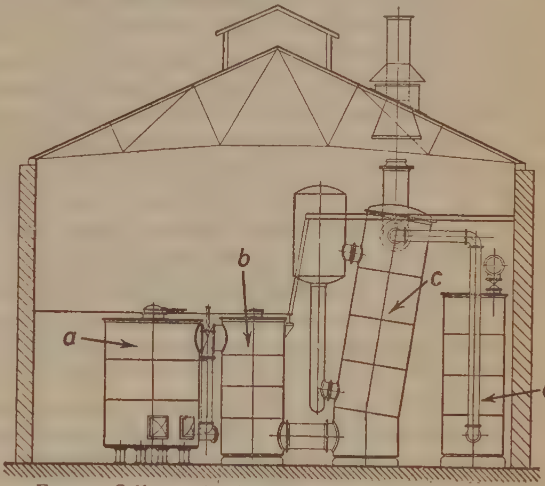

FIG. 2.—Self-steaming blue water-gas plant. (See text.)

Complete Gasification of Coal.—Complete gasification of coal in two steps is commercially successful. Numerous attempts have been made to effect complete gasification in one operation, but none appears to have been successful commercially. One of the earliest attempts was made many years ago by Fahnehjelm in the U.S.A.; his apparatus was a compact structure comprising a vertical conical retort, surrounded by heating flues and supported by a generator below. One of the many difficulties of this apparently simple process was that of obtaining in the generator a regular supply from the retort of incandescent coke suitable for yielding gas. A great deal has been achieved in Germany by extensive trials of Strache's apparatus, which is generally similar to Fahnehjelm's. The problem is, in fact, receiving careful attention and complete success may be achieved.

Low Temperature Carbonisation (*see* FUEL PROBLEMS).—This is a process for the partial destructive distillation of coal at temperatures which are low compared with those of an ordinary gas retort or coke oven; an important aim of the process is to obtain a smokeless fuel suitable for burning in ordinary grates. About 1865, experiments on partial destructive distillation of coal were made by Mr. Scott-Moncrieff, but the process which has led to a more intensive study of the subject is that patented by Mr. Thomas Parker (British Specification No. 14,365 of 1906), for subjecting bituminous coal to destructive distillation at a temperature of about 800° F., until illuminating gases cease to be evolved, then stopping the distillation and quenching the charge. This process, usually carried out in tubular iron retorts, was tried repeatedly and many improvements were made, especially by Low Temperature Carbonising, Ltd., whose retort plant, set up near Barnsley, operates at a temperature between 600° C. and 800° C.

Other investigators have worked processes of this kind. The South Metropolitan Gas Co. (London) has made experiments on low temperature carbonisation with a view to obtain a good quality smokeless fuel. An installation of rotary, inclined retorts, developed by Mr. Nielsen, has also been worked near Barnsley, the temperature of working being about 675° C. By these processes, a smokeless fuel, burning freely with a clear flame, and almost odourless, has been obtained, together with a moderately large quantity of a rich gas, and good yields of tar and ammonia. No plant, however, has been working, on a commercial scale, long enough to justify an assertion that the process is a success. Any plant for which it is claimed that the problem of low temperature carbonisation has been solved may be tested, free of cost, by the Fuel Research Board, so that the possibilities of the process are still being considered.

Bergius Process.—A process which has attracted a great deal of attention, especially in Germany, is the Bergius process, elaborated by Prof. Bergius. Experiments have been made at Mannheim and recently efforts have been made to carry out the process commercially. The chief aim of the process is to obtain oil from coal and it is claimed that coal of poor quality can be used advantageously. The coal is pulverised, mixed with oil residues from a previous operation, and heated to a temperature of about 450° C. in an atmosphere of hydrogen under a pressure of about 150 atmospheres. The product is a viscous mass from which the oils can be separated.

Gas Purification.—During the 15 years under review numerous improvements in the details of construction of gas purifying apparatus have been made, especially in connection with the grids and valves of purifier boxes. In modern gasworks water-cooled tubular condensers, bubble washers of the Livesey type, the Pelouze and Audouin type of tar extractors, and rotary brush scrubbers of the Holmes type are largely in use.

Attempts to introduce new purifying processes have been made. In Birkheiser's process, two rather small oxide purifiers, working together, are used, the crude gas being passed through one for removal of SH_2 while a blast of air is passed through the other to revivify the oxide by converting its absorbed SH_2 into SO_2; this SO_2 is used to recover ammonia. This process and a later modification were tried at the Tegel gasworks, Berlin, and also at Bournemouth, but, apparently, not with complete success.

Processes have been introduced by W. Feld, all ingenious, but most of them too complicated for commercial use. In one, used with success in Germany, the reagents employed are a solution of $FeSO_4$ for washing the crude gas and, in later steps of the cycle of operations, a mixture of SO_2 and air. Both SH_2 and NH_3 are eliminated from the gas, the ultimate products being ammonium sulphate and sulphur, which is filtered off, and thus recovered in solid form.

Gasholders.—Some exceptionally large gasholders have be erected during recent years. The largest gasholders in the wor appear to be those of the Astoria Gasworks, New York. T gasholders in course of erection at Birmingham are intended have five lifts and a total capacity of 20,000,000 cubic feet. A wat less, or tankless, gasholder recently erected in Michigan, is chamber of polygonal cross section with a capacity of 1,000,0 cubic feet. The chamber is closed by a piston, which moves up a down within it. A tar seal forms a gas-tight joint between t chamber and its piston and is a very important part of the wh construction. In countries where the winters are severe, a wat less gasholder offers advantages. (T.E.L.)

GASES, ELECTRICAL PROPERTIES OF (*see* 6.864). These va very greatly with the conditions to which the gas is exposed. gas in its normal condition is practically à non-conductor electricity even though it be the vapour of a good conductor li mercury. On the other hand, when it is exposed to such i fluences as cathode rays, Röntgen rays, intense electrical forc or the radiation from radioactive substances, it becomes a co ductor of electricity. The very delicate methods now at our d posal reveal however a trace of conductivity in gases where pr cautions have been taken to shield off the effects just mentione

The most important electrical property of a gas in a norm state is its specific inductive capacity. The significance of th property is best illustrated from the relation $(K-1)/$ $=NM$, between K, the specific inductive capacity; N, t number of molecules per unit volume, and M, the electrostat moment which a molecule acquires under unit electric force. we know N, we can if we know the value of K deduce the val of M, and this will tell us a good deal about the shape and si of the molecule. For example, if we regard the molecules solid conducting spheres, $M=r^3$ where r is the radius of t sphere. Thus, on this hypothesis we can find the radius of t molecule if we know the value of K, and though the hypothes itself does not throw much light on the structure of the atom, is probable that the radius of a conducting sphere which wou produce the same electrical moment would be of the same ord of magnitude as the linear dimensions of the molecule: the ra of metallic spheres which would give the specific inducti capacities possessed by hydrogen, nitrogen, oxygen and chlorin are respectively $1{\cdot}19\times10^{-8}$, $1{\cdot}60\times10^{-8}$, $1{\cdot}48\times10^{-8}$, $2{\cdot}04\times10$ centimetres. On the more probable hypothesis that the aton and molecules consist of electrons arranged round centres positive electricity, the electric force will displace the electro relatively to the positive centres and thus cause the molecule have a finite electrical moment. The more rigidly the electro are connected to the positive charge, the smaller will be th moment and the smaller the specific inductive capacity of the ga

The values of $K-1$ for the elements belonging to the sa family are connected by a remarkably simple and interesting r lation, which was discovered by Cuthbertson (*Phil. Trans.* A.20 p.135). It is shown in Table I. where the numbers under the sym bols denoting the elements are the values of $\frac{1}{2}(K-1)\times10^6$:—

TABLE I.

			He 144×½
N 297	O 270	F 192	Ne 137
P 1197 =299×4	S 1101 =275×4	Cl 768 =192×4	Ar 568 =142×4
As 1550 =258×6	Se 1565 =261×6	Br. 1125 =187×6	Kr 850 =142×6
	Te 2495 =249×10	I 1920 =192×10	X 1378 =138×10

Thus the values of $K-1$ for successive elements of the sam family—(N, P, As): (O, S, Se, Te): (F, Cl, Br I): (Ne, Ar, K X)—are in all cases very nearly in the proportion 1, 4, 6, 10. I the simple theory, where the molecules are regarded as condu tors, this would indicate that the volumes of the molecules of th uccessive elements in the same family are in the proportion 1, , 6, 10, for each of these types of elements. On the theory which egards the atom as built up of electrons arranged round positive entres, the configuration of the outer layer of electrons for different members of the same family would be similar, and it is asy to show that for similar configurations of electrons the alue of $K-1$ would be proportional to the cube of the linear imensions, *i.e.*, to the volume enclosed by the outer layer of lectrons; so that again on this theory Cuthbertson's result hows that volumes of successive elements in the same family are n the same ratio whether the family be that of the inert gases, he halogens, or the oxygen or nitrogen groups.

W. L. Bragg (*Phil. Mag.*, 40, p.169) using the method of Röntgen ray crystal analysis has measured directly the diameters f the atoms of many of the elements. He finds that the cubes f the diameters of F, Cl, Br, and I are proportional to 1, 3·72, ·45 and 8 respectively; those of O, S, Se to 1, 3·9 and 6, and hose of C and Si to 1, 3·6. Thus for these electronegative elements the ratio of the volumes of corresponding elements in two ifferent periods is approximately constant. This, however, is ot true for electropositive elements, where the sizes of the toms in one period increase much more slowly from one element o the next than they do for the electronegative elements.

Another example of the information as to the nature of the molecule afforded by determinations of the specific inductive apacity is that, while the specific inductive capacity of many ases, *e.g.*, H_2, N_2, O_2, CO, CO_2, Cl_2, is equal (as Maxwell's Electromagnetic Theory of Light suggests) to the square of the efractive index, there are, as Bädeker (*Zeitschrift Physik. Chem.*, 6, p.305) has shown, others, such as NH_3, HCl, SO_2, and the apours of water and the alcohols, whose specific inductive apacity is far in excess of the value given by this rule, and morever the specific inductive capacity of these gases diminishes much more rapidly as the temperature increases than that of ases of the first type. The difference can be accounted for by upposing that the molecules of gases of the first type have no lectrical moment when they are free from the action of an xternal electrical force, while those of the second type have an ntrinsic electrical moment apart from that which may be produced by the external force. When there is no electrical field, he collisions between the molecules will cause the axes of electrical moments of the different molecules to be uniformly distributed, so that the average effect will be zero. An electric orce will tend to drag the axes of the different molecules into lignment, and the assemblage of molecules will have a finite lectrical moment which will be a measure of the specific inductive capacity. Inasmuch as the collisions between the molecules end to knock their axes out of line and diminish the specific nductive capacity, the latter will diminish as the temperature nd with it the vigour of the encounters increases. The substances which have an intrinsic electrical moment have exceptionally active chemical properties and are good solvents, dissociating the salts dissolved in them.

If the distribution of electrons in a molecule were not symmetrical about three axes at right angles to each other, the pecific inductive capacity of a single molecule would vary with he direction of the electric force, but as the molecules in a gas are orientated in equal numbers in all directions we should not detect his by direct measurements of the specific inductive capacity. We can however detect this effect in another way; for if the molecules have different specific inductive capacities in different directions the light scattered by the molecules at right angles to he incident unpolarised light will not be plane polarised as it vould be if the molecule were symmetrical (J. J. Thomson, *Phil. Mag.*, 40, p. 393), and if the incident light is plane polarised he scattered light will not vanish in any direction. Strutt (now Lord Rayleigh) (*Proc. Roy. Soc.*, 98A, 57) has measured the departure from plane polarisation for different gases with the esults shown in Table II.

This shows that the molecule of argon is very symmetrical, while the nitrogen molecule is more symmetrical than that of oxygen, and this again more symmetrical than that of CO_2.

TABLE II.

Argon	0·46%
Hydrogen	3·83%
Nitrogen	4·06%
Air	5·00%
Oxygen	9·40%
Carbon dioxide	11·70%
Nitrous oxide	15·40%

Ionised Gases.—Gases may in various ways be put into a state in which they conduct electricity on an altogether different scale from the normal gas. They acquire this conductivity when Röntgen rays or the rays from radioactive substances pass through them, or when they are traversed by cathode or positive rays. Ultra-violet light of very short wave length can impart this property to a gas, while gases recently driven from flames or from near arcs or sparks or bubbled through certain liquids or passed slowly over phosphorus also possess this property.

The conductivity of gases possesses interesting characteristics. In the first place it persists for some time after the agent which made the gas a conductor has ceased to act; it always however diminishes after the agent is removed, in some cases very rapidly, and finally disappears. The conducting gas loses its conductivity if it is sucked through glass-wool, or made to bubble through water. The conductivity may also be removed by making the gas traverse a strong electric field so that a current of electricity passes through it. The removal of the conductivity by filtering the gas through glass-wool or water shows that the conductivity is due to something mixed with the gas which can be removed by filtration, while the removal of the conductivity by the electrical field shows that this something is charged with electricity and moves under the action of the electric force. Since the gas when in the conducting state shows as a whole no charge of electricity the charges mixed with the gas must be both positive and negative. We conclude that the conductivity of the gas is due to the presence of electrified particles; some of these particles are positively, others negatively, electrified. These electrified particles are called ions, and the process by which they are produced ionisation.

The passage of electricity through a conducting gas does not follow the same laws as the flow through metals and liquid electrolytes; in these the current is proportional to the electromotive force, while for gases the relation is represented by a graph like fig. 1, where the ordinates are proportional to the current and the abscissae to the electromotive forces. We see that when the electromotive force is small, the current is proportional to the electromotive force, as in the case of metallic conduction; as the electromotive force increases, the current after a time does not increase nearly so rapidly, and a stage is reached where the current remains constant in spite of the increase in the electromotive force. There is a further stage, which we shall consider later, where the current again increases with the electromotive force, and does so much more rapidly than at any previous stage. The current in the stage when it does not depend upon the electromotive force is said to be saturated. The reason for this saturation is that the passage of a current of electricity through the gas involves the removal of a number of ions proportional to the quantity of electricity passing through the gas. Thus the gas is losing ions at a rate proportional to the current; it cannot go on losing more ions than are produced, so that the current cannot increase beyond a critical value which is proportional to the rate of production of ions. This sometimes

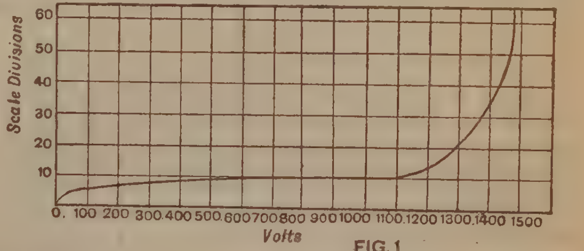

FIG. 1

produces a state of things which seems anomalous to those accustomed to look at conduction of electricity exclusively from the point of Ohm's law. For example, when gases are exposed to Röntgen rays, the number of ions produced per second is proportional to the volume of the gas, so that, if two parallel plates are immersed in such a gas and a current sent from one to the other, when the distance between the plates is increased the number of ions available for carrying the current and therefore the saturation current will be increased also. Thus the apparent " resistance " will diminish as the length of the gaseous conductor is increased.

The Nature of the Ions.—The question arises, what is the nature of the particles which carry the charges of electricity? Are they the atoms or molecules of the gas, or, for the negative charges, electrons? Information on these points is afforded by measuring the velocity with which the ions move through the gas under given electric forces.

The ion under the action of the electric force will soon attain a steady velocity which will be determined by the condition that the momentum communicated to the ion by the electric force in unit time is equal to the momentum lost by the ion in the same time by its collisions with the molecules of gas through which it is moving. Suppose that the average momentum lost by the ion per collision is qmu where m is the mass of the ion, u its velocity and q a quantity which will depend on the relative masses of the ion and the molecule and also on the force between the ion and the molecules, *e.g.*, if the ions and molecules behaved like elastice spheres q would not be the same as if they acted upon each other with forces varying inversely as the fifth power of the distance between them. The value of q will also depend on the electric charge on the ion. The number of collisions made by an ion with the molecules of the gas in time δt may be written as $\delta t/T$. Where T is the average interval between two collisions, T will vary inversely as the number of molecules in unit volume, *i.e.*, inversely as the density of the gas and will also depend upon the temperature and the masses of the ions and molecules. When the loss of momentum by collisions balances the gain from the electric force F

$$Fe\delta t = \frac{qmu\delta t}{T} \qquad (1)$$

$$\text{or } u = \frac{FeT}{mq}$$

we can determine by experiment the value of u/F and hence the value of T/mq. This will give us information as to the nature of the ions, *e.g.*, we can by the kinetic theory of gases calculate the values of T and q when the ion is a molecule of the gas and when the collision between an ion and a molecule is the same as that between two molecules; on these suppositions the calculated mobility is for most gases considerably greater than that found by experiment. The difference is to be explained by the effect of the electric charge on the collision and also the clustering of other molecules round the charged one to form a more complex ion. These two effects are not independent for it can be shown that if the effect of the charge is large enough seriously to affect the mobility, it follows by the Laws of Thermodynamics that the forces between the ions and the molecules must be great enough to lead to considerable aggregation at room temperatures. The effects to be expected from the formation of such aggregates may be illustrated from the expression for k, the mobility of the ion, *i.e.*, the velocity of the ion under unit force, deduced on the assumption that the force between the ion and the molecule varies inversely as the fifth power of the distance between them, this expression is

$$k = \frac{e}{2\pi N}\left\{\frac{M_1+M_2}{M_1\times M_2}\right\}^{\frac{1}{2}}\left\{1\cdot 1e\sqrt{(\mu^2-1)/N\pi}+\frac{s^2}{2}\sqrt{2\beta\theta}\right\}^{-\frac{1}{2}} \qquad (2)$$

where M_1, M_2 are the masses of the molecule and ion respectively, N the number of molecules per unit volume, μ the refractive index of the gas, s the sum of the radii of an ion and a molecule and $\beta\theta$ the energy of a molecule due to thermal agitation when θ is the absolute temperature of the gas. For most gases the effect of the term $s^2\sqrt{2\beta\theta}$ is insignificant. When this is so the effect of th complexity of the ion is represented by the term

$$\left(\frac{M_1+M_2}{M_1M_2}\right)^{\frac{1}{2}}.$$

This varies but slowly with the complexity, for when the ion co sists of a single molecule $M_2=M_1$ and the expression is $\sqrt{2/M}$ while when the ion consists of an infinite number of molecul the value is $\sqrt{1/M_1}$ thus this great increase in mass only reduce the mobility in the proportion of 1 to $\sqrt{2}$. The formula give above for k may be used to find the value of M_2/M_1 and f positive ions in most cases this ratio is found to be greater tha one. This indicates the formation of complex ions; these und the impact of the molecules break up and new aggregates a formed around the simple ions. This constant change of partne by the ions explains the very remarkable fact that in a mixture different gases all the ions appear to move with the same velocit Thus in a mixture of a light gas like hydrogen with a heavy o like methyl iodide we do not find ions of great mobility co responding to the hydrogen and others of smaller mobility co responding to the methyl iodide. Wellisch has shown that a the ions in the mixture move with the same velocity. If there ha been stable ions with masses comparable with the hydroge molecules and others comparable with the methyl iodide molecul they could easily have been differentiated. If however the io form aggregates and the partners of the ions in these aggregate are constantly changing so that during the life of the ion passes backwards and forwards through a great number different phases, then though at any particular instant one io might have a different mobility from another, yet the averag mobility taken over a finite time would be the same for all th ions. To detect the different kinds of ions it would be necessar to observe not their average behaviour over a long time but t make the measurements so quickly that the ion had not time t pass from one state to another whilst it was under observatio The life of an ion in a particular phase is, at atmospheric pressur probably considerably less than the millionth of a second; th length of life will vary inversely as the pressure so that the chanc of detecting the different kinds of ions would be much greater a low pressures than at high ones.

Lately Erikson has detected a case when the velocity of th ion changes even though the gas through which it is movin remains the same; he has shown that the mobility of the positiv ions in air at atmospheric pressure is, in the first second or so o their existence, about 1·89 but as the ions get older the mobilit falls to 1·35, the ratio of these numbers is nearly equal to √ which is the ratio of the mobility of an ion consisting of on molecule to that of one consisting of a very large number. I would thus seem that the old ions are much more complex tha the young ones. The surprising thing about Erikson's result i that he found the ions to retain their youthful properties for th best part of a second at atmospheric pressure; during this tim the ion will have collided with many million molecules of ai and so might have been expected to form partners in a very smal fraction of a second. The results are consistent with the ide that the ion forms a stable connection with the molecules of som very heavy gas present in very small quantities as an impurity The addition to the gas of small quantities of the vapours o water or alcohol whose molecules have a finite electrical momen produces a marked diminution in the mobility, indicating tha they give rise to aggregates of exceptional permanence. Formul (2) is obtained on the assumption that the force between the io and the molecule is due to electrostatic induction alone and s varies inversely as the fifth power of the distance; if the ga were one like water vapour or ammonia whose molecules ar polar, the force between the ion and the molecule would var inversely as the fourth instead of the fifth power of the distanc and the mobility would not be given by formula (2).

We see from this formula that unless M_2/M_1 depends upon th pressure the mobility is inversely proportional to N, *i.e.*, to th pressure of the gas. This law has been verified for positive ions own to pressures less than 1 mm. of mercury. As however the robability of forming complex aggregates is greater at high than t low pressures, we should expect M_2/M_1 to diminish as the ressure diminishes; this diminution in M_2/M_1 would produce a nall increase in the mobility so that the formula would indicate hat the mobility would increase just a little more quickly than he reciprocal of the pressure.

The behaviour of negative ions is in many respects quite ifferent from that of the positive ones. In the first place the obility of the negative ions is for the permanent gases greater han that of the positive; thus, for example, in dry hydrogen the elocities of the negative and positive ions, when the electric rce is one volt per cm., are 7·95 and 6·7 respectively, and for r 1·87 and 1·36. The difference is less for moist gases than for ry, while for complex vapours which have comparatively small obilities Wellisch found that there was very little difference etween the mobilities of the positive and negative ions.

For the permanent gases the ratio of the mobilities of the egative and positive ions varies but little with the pressure, un-l the pressure is reduced below that represented by about 10 n. of mercury. For lower pressures than this, the mobility of he negative ion increases, as Langevin showed, more rapidly han that of the positive; at the pressure of a millimetre or so the obility of the negative ion in air may be three or four times that f the positive.

An even more interesting result was discovered by Franck nd Hertz, who, when they experimented with very carefully urified nitrogen or argon, found that the mobility of the egative ion was more than 100 times that of the positive. The obilities in these gases are extremely sensitive to traces of oxy-en, and a fraction of 1% of oxygen added to the pure gas will duce the mobility of the negative ion to less than one-tenth f its maximum value. The enormous mobility of the negative n in nitrogen and argon as compared with that of the positive hows that in them the negative electricity must be carried by ectrons and not by atoms or molecules, while the effect of troducing traces of oxygen shows that these electrons readily tach themselves to the molecules of oxygen though they are nable to adhere to molecules of nitrogen or argon. The same fect has also been observed in helium and hydrogen.

These properties of the negative ion are of great importance connection with the mechanism of ionisation in gases and the ructure of atoms and molecules. In the first place, they rnish strong evidence in support of the view that the first stage the ionisation of a gas is the ejection of an electron from the olecule of the gas rather than the separation of the molecule to atoms of which some are charged with positive and others ith negative electricity. On this view the negative ion begins s career as an electron and not as an atom, while the positive n from the beginning is of molecular dimensions. As an elec-ron has much greater mobility than a molecule the mobility of e negative ion will at first be much greater than that of the ositive. In some gases, such as oxygen, the electron soon gets tached to a molecule, and its mass and mobility become com-rable with those of the positive ion. The mobility we measure the average mobility of the negative ion during its life; part the time its mobility, being that of an electron, is very much rger than that of the positive ion, while in the other part the o mobilities will be much the same. The excess of mobility of e negative over the positive ion will depend upon the fraction its life which the negative ion spends as a free electron—a action which would tend to increase as the pressure of the gas minished.

The mobility of the electron may be estimated by formula); if the gas is nitrogen we must in that formula put $M_2/M_1=$ 28×1800 which is the ratio of the mass of an electron to that a nitrogen molecule. Using this value for M_2/M_1 we find at the mobility of the electron is about 220 times that of e positive ion, a result which is confirmed by experiment. irect experiments on the mobility of negative ions do not give y indication of the existence of two kinds of these ions. This ay be regarded as a confirmation of the explanation of the similar result for the positive ions, viz.: that our methods only give the average mobility of the ion through a comparatively long life; for there can be but little doubt that in all but a very few gases the negative ion can exist in two phases, one of them being the electron. The mobility in the electron phase is so exceptional that anything which prolongs the duration of this phase in comparison with that of the other phases must have a great effect upon the mobility. Some observations by Loeb (*Phys. Review*, 17, p.89) give us some information about the time an electron in oxygen requires to unite with the molecule and form a negative ion. He found that the electron made about 50,000 collisions with an oxygen molecule before combining with it and that this number is independent of the pressure. The time taken to make these collisions, taking the velocity of the electron at 0° C. as 10^7 and the free path as 10^{-5} at 760 mm., is 5×10^{-8} sec. and this will measure the life of the free electron. It is evident that, even allowing for the great mobility of the electron, it could not appreciably affect the mobility in experiments lasting for a time comparable with ·01 sec., and the mobility would be practically that of the negative ion, unless the electron were able to break away again from a molecule after it had united with it. The mobility of the carriers of negative electricity as compared with that of the positive one is evidence that the electron is continually changing partners. If k_1 be the mobility of the electron, k_2 that of the negative ion, T_1 the life of the electron, T_2 that of the negative ion, the average mobility will be

$$\frac{k_1T_1 + k_2T_2}{T_1 + T_2}$$

If p is the pressure of the gas, k_1 and k_2 vary inversely as the pressure, let them equal K_1/p, K_2/p, then the mobility is equal to

$$\frac{1}{p}\left\{\frac{K_1T_1 + K_2T_2}{T_1 + T_2}\right\} \quad . \quad (3)$$

Since Loeb's experiments show that the electron makes the same number of collisions before uniting with the molecule whatever be the pressure, and since the interval between each collision is inversely proportional to the pressure, T_1 varies as $1/p$, if the breaking up of the negative ions were due to collisions with the molecules T_2 would also vary as $1/p$ and the ratio of T_1 to T_2 would be independent of the pressure. This from equation (3) would make the mobility of the negative ion like that of the positive vary inversely as the pressure and would not explain the abnormal increase of the negative carriers at low pressures. Hence we conclude that the breaking up of the negative ions is not due to collisions. If T_2 is independent of p, while T_1 increases as p diminishes the product of the mobility and pressure will by (3), since k_1 is greater than k_2, increase as p diminishes, which is in accordance with the results observed by Langevin and others.

The difference between the behaviour of the electron in nitrogen or argon and in oxygen discovered by Franck and Hertz is of great importance in connection with the structure of the atom and molecule, for it indicates that, while a molecule of oxygen can accommodate another electron in addition to those already present, the molecules of nitrogen and argon are unable to do so. It is instructive therefore to consider the results obtained by the study of the positive rays as to the power of the atoms and molecules of the different elements to acquire a negative charge. These show that, while the atoms of hydrogen, carbon, oxygen, fluorine or chlorine readily acquire a negative charge, those of helium, nitrogen, neon and argon do not; and again that, while it is very exceptional for a molecule whether of a compound or an elementary gas to acquire a negative charge, the molecule of oxygen is able to do so. We see that this result is in accordance with the behaviour of the carrier of the negative charge in an ionised gas. Since the atoms in the positive rays show so much greater affinity for the electrons than the molecules, it follows that if the agent producing ionisation were to dissociate some of the molecules of the gas into neutral atoms (and to do this would require the expenditure of much less energy than to ionise the gas), these atoms would be much more effective traps for the electrons than the undissociated molecules. Loeb has shown that even in oxygen an electron collides on the average with about 50,000 molecules of oxygen before it is captured; thus if the oxygen *atom* could capture an electron at the first encounter, if only one molecule in 50,000 were dissociated into atoms, the effect of the atoms would be as efficacious as that of the molecules in capturing the electrons. When this dissociation into atoms takes place the abnormal velocity of the negative ion will only occur in gases like nitrogen and the inert gases whose *atoms* cannot receive an electron.

Recombination of the Ions.—Even when the ions are not removed from a gas by sending a current of electricity through it, their number will not increase indefinitely with the time of exposure of the gas to the ionising agent. This is due to the recombination which takes place between the positive and negative ions; these ions as they move about in the gas sometimes come into collision with each other, and by forming electrically neutral systems cease to act as ions. The gas will reach a steady state with regard to ionisation when the number of ions which disappear in one second as the result of the collisions is equal to the number produced in the same time by the ionising agent.

If there are n ions of either kind per cu. cm., the number of collisions between the positive and negative ions in one second in a cu. cm. of the gas will be proportional to n^2; hence the number of ions of either sign which are lost by recombination in one second may be represented by αn^2 when α is called the coefficient of recombination. If the ionising agent produces q ions per cu. cm. per sec., then

$$\frac{dn}{dt} = q - \alpha n^2.$$

The solution of this equation, if we reckon t from the instant the ionising agent begins to act, so that $n=0$ when $t=0$, is $k^2=q/\alpha$

$$n = \frac{k(\epsilon^{2k\alpha t}-1)}{\epsilon^{2k\alpha t}+1}.$$

We see that, when the gas reaches a steady state, $n=k=\sqrt{q/\alpha}$, and that the gas will not approximate to this state until t is large compared with $1/2k\alpha$, *i.e.*, to $1/2\, n_0\alpha$ where n_0 is the value of n in the steady state. Thus when the ionisation is very weak it may take a considerable time for the gas to reach a steady state.

When the ionising agent is removed, the ions do not disappear at once, but decay at the rate given by the equation

$$\frac{dn}{dt} = -\alpha n^2.$$

The solution of this, when t is the time which has elapsed since the removal of the ionising agents, and n_0 the number of ions when $t=0$, is

$$n = n_0/(1+n_0\alpha t).$$

Thus the number of ions will be reduced to one-half their initial value after a time $1/\alpha n_0$. We may therefore take $1/\alpha n$ as the measure of the life of an ion when there are n ions per cubic centimetre. The values of α/e, where e is the charge on an ion, have been measured by various experimenters; the results are given in the following table: the agent used to ionise the gas is given in the second row.

TABLE III.

Values of α/e for Various Gases at Atmospheric Pressure and Ordinary Temperature

Gas	Townsend	McClung	Langevin	Thirkill	Hendren	Retschinsky	Rumelin	
	Röntgen rays	Röntgen rays	Röntgen rays	Röntgen rays	α rays	α rays	α rays	β rays
Air	3,420	3,380	3,200	3,580	3,300	4,200	4,240	5,820
CO_2	3,520	3,490	3,400	3,500	..	..	..	..
H_2	3,020	2,940	..	..	..	..	..	..
O_2	3,380	..	..	..	..	..	..	..
SO_2	..	..	..	3,000	..	..	..	..
N_2O	..	..	..	2,960	..	..	..	..
CO	..	..	..	1,780	..	..	..	..

The results ascribed to Thirkill were obtained by extrapolati from experiments made at lower pressures. Since e, in electr static measure, is $4{\cdot}8\times10^{-10}$, the value of α for air is about $1{\cdot}6$ 10^{-6}, so that, when there are n positive and n negative ions p cu. cm., the number of ions which recombine per second

$$1{\cdot}6\times10^{-6}n^2.$$

This shows very markedly the influence of the electric charg in increasing the number of collisions between the particles, f the number of collisions in a second between $2n$, uncharge molecules in a cu. cm. of air is

$$4\times10^{-10}n^2.$$

which is only about 1/4,000 of the number of recombinatio between the same number of ions.

The ions like the molecules of the gas will in consequence thermal agitation be moving with high velocities, and unless th distance between them is less than a certain value will drift apa and not combine. The condition that they should not separat if they are a distance d apart is that the kinetic energy due t their relative motion should be less than e^2/d the work require to separate the ions to an infinite distance. The average kineti energy due to their relative motion is equal to $\beta\theta$ where $\beta\theta$ the average kinetic energy of a molecule at the absolute te perature θ; β is equal to $2{\cdot}02\times10^{-16}$. Hence the ions will separat unless

$$2{\cdot}02\times10^{-16}\theta < e^2/d.$$

At 0° C, $\theta=273$ and since $e=4{\cdot}8\times10^{-10}$ this condition shows tha they will separate at this temperature unless d is less than $4{\cdot}1$ $\times10^{-6}$ centimetres. This is on the supposition that they are n subject to any influence other than their mutual attraction. A they move through the gas they may, if one or other of the when they are close together comes into collision with a molecul of the gas, lose some of the kinetic energy which would enabl them to separate. Assuming that collision with a molecule r duces the kinetic energy due to relative motion to $\beta\theta$, the valu it has for thermal equilibrium, it follows that to ensure combin tion the collision with the molecules must occur when d, th distance between the ions, is less than $e^2/\beta\theta$ and that every su collision leads to recombination. To find the rate at which th ions recombine we have to find the number of collisions betwee ions and molecules which occur in one second, only those co lisions to be counted when an ion is within a distance d of one opposite sign at the time of collision. It can be shown (s J. J. Thomson, *Phil. Mag.*, 47, p. 337) that this number is equal t

$$\pi d^2\rho\rho^1\sqrt{U^2+U_1^2}(1-\omega\omega^1)$$

where $$\omega = \frac{\lambda^2}{2d^2}\left(1-\epsilon^{\frac{-2d}{\lambda}}\left[1+\frac{2d}{\lambda}\right]\right)$$

$$\omega^1 = \frac{\lambda_1^2}{2d^2}\left(1-\epsilon^{\frac{-2d}{\lambda_1}}\left[1+\frac{2d}{\lambda_1}\right]\right)$$

where λ and λ_1 are respectively the mean free paths of th positive and negative ion through the gas, U and U_1 the mea velocities of these ions due to their thermal agitation, ρ and ρ the number of positive and negative ions per unit volume a $d=e^2/\beta\theta$.

It follows from the definition that α the coefficient of recom bination is given by the equation

$$\alpha = \pi d^2\sqrt{U^2+U_1^2}\,(1-\omega\omega^1).$$

When the pressure is low enough to make $2d/\lambda$ and $2d/$ small, then $1-\omega\omega^1 = \frac{4}{3}d\left(\frac{1}{\lambda}+\frac{1}{\lambda_1}\right)$ approximately,

so that $\alpha \doteq \frac{4}{3}\pi d^3\sqrt{U^2+U_1^2}\left(\frac{1}{\lambda}+\frac{1}{\lambda_1}\right).$

Both $1/\lambda$ and $1/\lambda_1$ are proportional to the pressure, so that at lo pressures α varies as the pressure, which agrees with the result of Thirkill's experiments. When the pressure is so high tha λ/d and λ_1/d are small, ω and ω^1 are small and

$$\alpha = \pi d^2\sqrt{U^2+U_1^2}$$

approximately, so that α is independent of the pressure.

When the density is constant the value of α diminishes as the mperature increases. The connection between α and the ablute temperature T seems to be expressed with fair accuracy by e equation

$$\alpha = c\mathrm{T}^{-n}$$

cording to Erikson, n is equal to 2·3, 2·42, 2·35 for hydrogen, and CO_2 respectively, while Phillips's experiments gave $n=2$.

Diffusion of Ions.—In addition to the loss of ions by recomnation, there will be a loss due to the diffusion of the ions to e side of the vessel in which they are contained; when the ions ike against the walls they may lose their charges and thus ase to be ions. The loss of ions from this cause will be prortional to the surface of the vessel, while that due to recomnation will be proportional to the volume, thus the ratio of the ss by diffusion to that by recombination will be greater in small ssels than in large. Again the rate of diffusion is inversely oportional to the pressure while that of recombination is dictly proportional to it, thus the loss by diffusion will be relavely more important at low pressures than at high.

Large Ions.—The ions we have been considering are those proced in dust-free gases by Röntgen or cathode rays. In some ses, however, ions with very much lower mobilities are to be und in gases. Thus Langevin found in air from the top of the iffel Tower two types of ions, one consisting of ions of the kind e have been considering, with a mobility of about 1·5 cm./sec., e other of ions with a mobility of 1/3,000 cm./second. Ions ith mobilities of the same order as this second type may be oduced by bubbling air through water, by passing air over osphorus or by drawing air from the neighbourhood of flames. hey are probably charged particles of dust of various kinds, held suspension in gas which is exposed to some kind of ionising gent which gives a supply of ions of the first type; these settle the particles of dust and form the slow ions. The number of ese slow ions, when the gas is in a steady state, will depend only the number of dust particles in the gas and will not be affected the strength of the ionising agent. This follows from the inciple that in the steady state the number of dust particles hich acquire a positive charge must equal the number which se such a charge. A positively electrified dust particle might se its charge by meeting and coalescing with a negative small n or by coalescing with a negatively electrified dust particle. hese dust particles are, however, so sluggish in their moveents that, unless the dust particles are enormously more merous than the small ions, we may neglect the second source loss in comparison with the first.

Thus if U is the number of uncharged dust particles in a cu. n. of the gas, P and N the number of those with positive and egative charges respectively and p, n, the number of positive nd negative small ions, then the number of dust particles which quire per second a positive charge will be $\alpha \mathrm{U} p$ and the number sing such a charge by coalescing with a negative ion $\beta \mathrm{P} n$, here α and β are constants; hence for equilibrium

$$\alpha \mathrm{U} p = \beta \mathrm{P} n$$

Similarly by considering the negatively charged particles we et

$$\alpha' \mathrm{U} n = \beta' \mathrm{N} p$$

ence we see that the proportion between the charged and unharged particles of dust depends only upon the ratio of p to n, nd not upon the absolute magnitude of either of these quanties. Thus, though it would take much longer to reach the eady state with a feeble source of ionisation than with a strong ne, when that state was reached there would be as much dust ectrified in one case as in the other. De Broglie estimates that this state about one-tenth of the particles would be electrified.

Relation Between the Potential Difference and the Current hrough an Ionised Gas.—We shall take the case of two infinite arallel metal plates maintained at different potentials and imersed in an ionised gas; the line at right angles to these plates e shall take as the axis of x, it being evidently parallel to the irection of the electric force X. Let n_1, n_2 be respectively the umber of positive and negative ions at the place fixed by the co-ordinate x; u_1 and u_2 the velocities of these ions. The volume density of the electrification in the gas, if it is entirely due to the ions, is $(n_1-n_2)e$ when e is the charge on an ion, hence

$$\frac{d\mathrm{X}}{dx} = 4\pi(n_1-n_2)e \qquad (1)$$

If ι is the current through a unit area of the gas

$$\iota = e(n_1u_1+n_2u_2) \qquad (2)$$

Hence from (1) and (2) we have

$$n_1e = \frac{\iota}{u_1+u_2}+\frac{1}{4\pi}\frac{u_2}{u_1+u_2}\frac{d\mathrm{X}}{dx} \qquad (3)$$

$$n_2e = \frac{\iota}{u_1+u_2}-\frac{1}{4\pi}\frac{u_1}{u_1+u_2}\frac{d\mathrm{X}}{dx} \qquad (4)$$

When things are in a steady state, neglecting any loss of ions by diffusion we have

$$\frac{d}{dx}(n_1u_2) = q-\alpha n_1n_2 \qquad (5)$$

$$-\frac{d}{dx}(n_2u_2) = q-\alpha n_1n_2 \qquad (6)$$

where q is the number of ions produced per second in a cu. cm. of gas, and α is the coefficient of recombination; if k_1, k_2 are the mobilities of the positive and negative ions respectively, then

$$u_1=k_1\mathrm{X} \qquad u_2=k_2\mathrm{X}$$

From equations (1), (5) and (6) we get

$$\frac{d^2\mathrm{X}^2}{dx^2} = 8\pi e(q-\alpha n_1n_2)\left(\frac{1}{k_1}+\frac{1}{k_2}\right)$$

and, substituting the values of n_1 and n_2, we get

$$\frac{d^2\mathrm{X}^2}{dx^2} = 8\pi e\left(\frac{1}{k_1}+\frac{1}{k_2}\right)\left\{q-\frac{\alpha}{e^2\mathrm{X}^2(k_1+k_2)^2}\left(\iota+\frac{k_2}{8\pi}\frac{d\mathrm{X}^2}{dx}\right)\left(\iota-\frac{k_1}{8\pi}\frac{d\mathrm{X}^2}{dx}\right)\right\} \qquad (7)$$

No general solution of this equation has been obtained, but when ι is small compared with the saturation current qle, l being the distance between the plates, an approximate solution is represented by the graph in fig. 2.

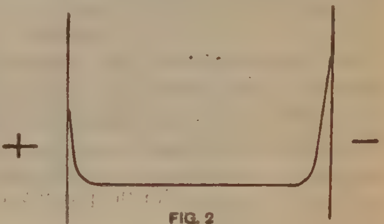

FIG. 2

The force is practically constant, and equal to

$$\left(\frac{\alpha}{q}\right)^{\frac{1}{2}}\frac{\iota}{e(k_1+k_2)}$$

except close to the electrode, where it increases; and as the mobility of the negative ion is greater than that of the positive the increase in the force will be greater at the cathode than at the anode. As the potential difference between the electrode increases, and the current approaches more nearly the saturation value, the flat part of the graph diminishes, and the graph for X takes the form given in fig. 3. When the potential difference is so large that the current is nearly saturated, X is very approximately constant from one electrode to another.

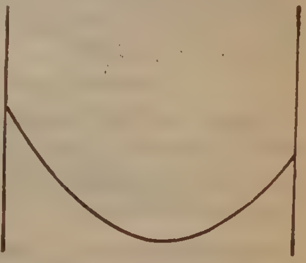

FIG. 3

In one extremely important case, that in which the negative ions are electrons and have a mobility which may be regarded as infinite in comparison with that of the positive ions, equation (7) admits of integration: for by putting $k_1/k_2=0$ in equation (8) it becomes

$$\frac{d\mathrm{X}^2}{dx}+\frac{8\pi e^2k_2q\mathrm{X}^2}{\alpha\iota} = \frac{8\pi\iota}{k_2} \qquad (8)$$

The solution of this is

$$\mathrm{X}^2 = \frac{\alpha\iota^2}{qk_2^2e^2}\left(1+\frac{k_2}{k_1}\frac{\iota-\iota_0}{\iota}\epsilon^{\frac{-8\pi e^2k_2q\mathrm{X}}{\alpha\iota}}\right) \qquad (9)$$

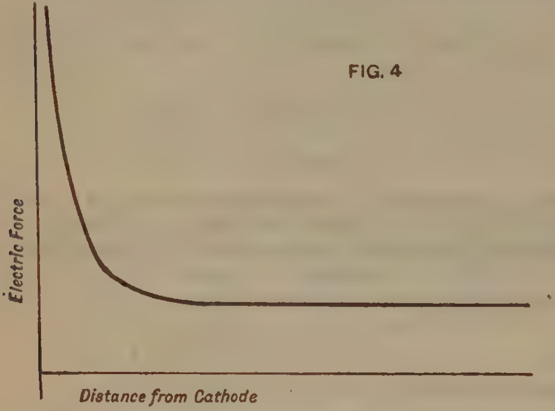
when x is the distance from the cathode and ι_0 the amount of negative electricity emitted by unit area of the cathode per unit time.

This distribution of force is represented by the graph in fig. 4; the force at some distance from the cathode is equal to

$$\frac{\iota}{k_2}\left(\frac{a}{q}\right)^{\frac{1}{2}}$$

and is thus proportional to the current; the force at the cathode itself is $\left\{1+k_2(\iota-\iota_0)/k_1\iota\right\}^{\frac{1}{2}}$ times greater than this. The fall of potential between the electrodes is made up of two parts, one arising from the constant force; as this force is proportional to ι this part of the potential fall will be proportional to ιl when l is the distance between the electrodes, and may be represented by $A\iota l$ when A is a constant; the other part of the potential fall is that which occurs close to the cathode. We find from equation (9) that this is proportional to ι^2 and does not depend upon l. Thus, if V is the potential difference between the electrodes when A and B are constants

FIG. 4



$$V = A\iota l+B\iota^2. \qquad (10)$$

H. A. Wilson has shown that an equation of this type represents the relation between the current and potential difference for conduction through flames. In many cases the drop of potential at the cathode is much greater than the fall in the rest of the circuit; when this is so we see that the current is proportional to the square root of the potential difference. The value of B increases with the pressure and decreases with the amount of the ionisation.

Current from Hot Wires.—A case of great importance from its industrial application in hot wire valves is one where all the ions are negative and are emitted from the cathode. Metal wires or plates raised to incandescence emit electrons, and if they are used as cathodes can transmit across a vacuum or gas at a low pressure very considerable currents.

Let the hot cathode be the plate $x=0$ and let V be the potential at the point x, n the density of the negative ions at this point, and ι the current through unit area. If u is the velocity of the negative ion, we have

$$nue = \iota \quad \text{and} \quad \frac{d^2V}{dx^2} = 4\pi ne.$$

There are two cases to be considered; the first is when the hot plate is surrounded by gas of sufficient density to make the velocity of the ions proportional to the electric force; the second is when it is surrounded by a vacuum, and the motion of the ions is not affected by the gas.

In the first case $u=k_2\dfrac{dV}{dx}$, when k_2 is the mobility of the negative ion, and the equation $nue=\iota$ is equivalent to

$$\frac{k_2}{4\pi}\frac{dV}{dx}\frac{d^2V}{dx^2} = \iota. \qquad (11)$$

The solution of this is

$$\left(\frac{dV}{dx}\right)^2 = \frac{8\pi\iota}{k_2}x+C.$$

Therefore if V is the difference of potential between the ano and cathode, and l the distance between them

$$V = \frac{k}{12\pi\iota}\left[\left(\frac{8\pi\iota l}{k}+C\right)^{\frac{3}{2}}-C^{\frac{3}{2}}\right] \qquad (1$$

where C is the constant of integration.

In consequence of thermal agitation some of the electrons ne the plate will diffuse backwards and hit the plate; if n_0 is t density of the electrons near the plate it follows from the Kine Theory of Gases that the number hitting the plate in unit tir is $n_0c/\sqrt{6\pi}$, where c is the velocity of mean square, *i.e.*, $\frac{1}{2}m$ $=\frac{3}{2}R\theta$; m is the mass of an electron, θ the absolute temperatu of the electrons and R the gas constant $1{\cdot}35+10^{-16}$.

If I is the current per unit area emitted by the plate, then consequence of the diffusion there is a backward curre $en_0c/\sqrt{6\pi}$, so that ι, the current going through the gas is given the equation

$$I-\frac{en_0c}{\sqrt{6\pi}} = \iota.$$

If u_0 is the velocity acquired by the electrons near the pla under the electric force, $\iota=en_0u$, hence

$$\frac{\iota}{I-\iota} = \frac{u_0}{c}\sqrt{6\pi}. \qquad (1$$

So that, unless ι is small compared with I, u_0 will be comparab with c; in this case, however, the velocity of the ion is no long proportional to the electric force so that equation (11) no long holds. Again, when the current approaches saturation, $\iota/(I-$ is large and therefore by (13) u_0 will be large compared with For the negative ion to acquire a velocity of this magnitude th electric field would have to be so strong that sparks would pa through the gas unless the pressure were very low. Thus satura tion currents from hot bodies are only obtainable at very lo pressures.

Since the electric force when $x=0$ is $\sqrt{C}$, $u_0=k\sqrt{C}$, an therefore by (13)

$$C = \frac{c^2}{6\pi k^2}\frac{\iota^2}{(I-\iota)^2}.$$

Thus if the current is far from saturation, C will be negligib compared with $8\pi\iota l/k$. When C can be neglected, equatio (12) gives

$$\iota = \frac{9k}{32\pi}\frac{V^2}{l^3}. \qquad (14$$

Thus the current is proportional to the square of the potenti difference. A remarkable thing about this expression is that fo these very small currents the intensity of the current is ind pendent of the temperature of the plate, although, of course, th range of currents over which this formula is applicable is wid the higher the temperature.

When the hot body is in a vacuum, we have, if the ions have n initial velocity,

$$\tfrac{1}{2}mu^2 = Ve$$

where m is the mass and e the charge on an ion; hence th equation $nue=\iota$ is equivalent to

$$\frac{d^2V}{dx^2}V^{\frac{1}{2}} = 4\pi\iota\sqrt{m/2e} \qquad (15$$

a solution of which is

$$V = (9\pi\iota)^{\frac{2}{3}}(m/2e)^{\frac{1}{3}}x^{\frac{4}{3}}. \qquad (16$$

Hence, if V is the potential difference and l the distance betwee the electrodes

$$\iota = \frac{l}{9\pi l^2}\left(\frac{2e}{m}\right)^{\frac{1}{2}}V^{\frac{3}{2}}. \qquad (17$$

We see from equation (16) that the electric force vanishes a the cathode, and that the density of the negative electrificatio is as $x^{-\frac{2}{3}}$; thus it is infinite when close to the cathode and diminishes as the distance from the anode diminishes. The total quantity of electricity between the anode and cathode is proportional to $(l\iota^2)^{\frac{1}{3}}$. We see again that for a given potential ifference the current does not depend on the temperature of the ot wire; this law only holds when the currents are less than the aximum currents which can pass between the electrodes. Vhen the current approaches this value, the current instead of icreasing as $V^{\frac{3}{2}}$ becomes independent of V, and the negative ectricity between the electrodes diminishes as V increases. angmuir, who has made a very complete investigation of the urrents from hot wires, finds that the expression (17) represents, ith considerable accuracy, the relation between the current and otential over a wide range in the values of the currents. The urves in fig. 5, given by him, represent the relation between the urrent and potential for wires at different temperatures. They lustrate the point that a colder wire, until it is approaching the tage of saturation, gives as large a current as a hotter one, hough the hotter one, of course, has a wider range of currents.

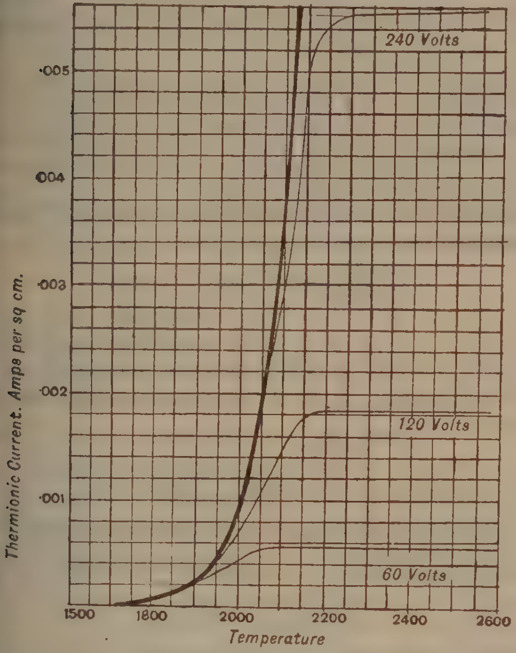


FIG. 5

Ionisation by Collision.—The curve representing the relation etween the currents through a gas ionised (say) by Röntgen ays and the difference of a potential between the electrodes is ound to be of the form already shown in fig. 1, where the orinates represent the currents and the abscissae the potential ifference. The flat part represents the state of saturation when he potential difference is large enough to send all the ions prouced by the rays to the electrodes before they can recombine. Vhen the potential difference is still further increased we see hat a stage is reached when the current begins to increase with reat rapidity with the potential difference, and reaches values uch greater than could be attained by the ions produced by he Röntgen rays. Thus in addition to the ions produced by the ays there must be other ions, and some other source of ionisation ssociated with the strong electric fields. Now the processes oing on in a gas while it is conveying an electric current are:—) the ionisation of the gas by the external agent—in this an lectron is liberated from the molecule and the residue forms a ositive ion; (2) the electron and the positive ion acquire energy nder the action of the electric forces; (3) in many gases the lectron finally unites with an uncharged molecule to form a egative ion. As the most noticeable change in the conditions hen the intensity of the electric field increases is in the energy f the electrons and ions, it is natural to look to these as the ource of the additional ionisation. We have, moreover, direct xperimental evidence that rapidly moving electrons and ions re able to ionise a gas through which they are passing. Hot wires and metals exposed to ultra-violet light yield a supply of electrons which when they leave the metal have very little energy; by applying suitable electric fields these electrons can be endowed with definite amounts of energy and can then be sent through a gas from which all extraneous ionising agencies are shielded off. When this is done it is found that, when the energy of the electrons exceeds a certain critical value, depending upon the nature of the gas, the gas is ionised by the electrons, but no ionisation occurs when the energy of the electron falls below this limit. It is convenient to measure the energy of the electron in terms of the difference of electrical potential through which the electron has to fall in order to acquire this energy. The potential difference which would give to the electron the energy at which it begins to ionise the gas is called the ionising potential. The values of the ionising potential have been found for several gases, as will be seen from Table IV. There is, however, considerable discrepancy between the results obtained by different observers.

TABLE IV. *Ionising Potentials in Volts.*

Zn .	..	..	..	..	9·5	..

The most obvious view to take of this ionisation by moving electrons is that the moving electron comes so near to an electron in a molecule of the gas that the latter receives from the collision enough energy to enable it to escape from the molecule and start as a free electron. If the electrons repel each other with forces varying inversely as the square of the distance between them, and if T is the energy of the moving electron, and d the length of the perpendicular from the electron in the molecule on the initial direction of motion of the moving electron, then the energy communicated to the electron in the molecule by its collision with the moving electron is equal to

$$\frac{T}{1+\frac{d^2T^2}{e^4}}$$

where e is the charge of electricity on an electron. This is on the supposition that the electron is moving so rapidly that the time while it is in close proximity to the electron in the molecule is small compared with the time of vibration of that electron; if this time is comparable with the duration of the collision, the energy taken from the moving electron will be considerably less, and it will become vanishingly small when the duration of the collision is large compared with the time of vibration. The energy given to the electron in the molecule does not increase indefinitely with that of the moving electron, for it vanishes when T is infinite as well as when T is zero; it has the maximum value when $T=e^2/d$. In order that the electron in the molecule should receive an amount of energy Q

$$Q=\frac{T}{1+\frac{d^2}{e^4}T^2}, \quad \text{or} \quad d^2=\frac{e^4(T/Q-1)}{T^2}$$

If Q is the ionising potential, d^2 must be less than the value given by this expression. If n is the number of *electrons* in unit volume of the gas, and if the spheres with radius d described round the different electrons do not overlap, the probability that the moving electrons should come within this distance of one of them, when moving through a distance Δx, is $n\pi d^2\Delta x$, or

$$\frac{n\pi e^4(T/Q-1)}{T^2}\Delta x$$

The coefficient of Δx is the number of ions made per unit path by a moving electron with energy T. The maximum is when $T=2Q$.

Experiments on ionisation by moving electrons have been made by Kössel (*Ann. der Phys.* 37, p. 406) and by Mayer (*ibid.* 45, p. 1), who found that the maximum ionisation per unit path occurred when the energy of the moving electron was in the neighbourhood of 200 volts. Mayer's results are 125 for hydrogen, 130 for air, and 140 for carbon dioxide. These numbers are much greater than twice the potential at which the ionisation begins, as this potential is of the order of 11 volts. It must be remembered, however, that though there may be some electrons in the atom which can be ejected by 11-volt electrons, there may be other electrons of different types which require more energy for their expulsion, so that, as the energy of the moving electrons increases beyond the energy required to liberate these electrons, fresh sources of detachable electrons will be trapped, and these may more than counterbalance the falling off in the ionisation of the more easily detached electrons. Again, some of the electrons ejected by the primary electrons may have enough energy to ionise on their own account; the total ionisation may thus be increased by ionisation due to the secondary electrons, and also by radiation excited by the impact of the primary electrons against the molecules of the gas.

When, as in the case of cathode rays in highly exhausted tubes or in that of the β rays from radioactive substances, T is very large compared with Q, the number of ions produced per unit path is $n\pi e^4/QT$, and so varies inversely as the energy of the moving electrons. The experiments of Glasson on ionisation by cathode rays, and of Durack on that by β-particles, seem to be in accordance with this result.

Scattering of Electrons.—The researches of Lenard and Ramsauer on the scattering of electrons in their passage through gases, have shown that the relation between the scattering produced by different gases depends to a great extent upon the velocity of the electrons which are scattered. If this velocity is small the scattering by most gases is approximately that which would be produced by impenetrable atoms of the size indicated by the Kinetic Theory of Gases and derived from the measurements of viscosity of gases and so on, there is no clear connection between the scattering produced by a gas and the number of electrons in its atoms. With high speed electrons the laws are much simpler and show proportionality between the scattering and the number of electrons in the atom. We should expect these results on the theory just given. For if 2θ is the angle through which the relative velocity of the electron and the atom is deflected by the collision

$$\sin^2\theta = \frac{1}{1+\dfrac{d^2}{e^4}T^2}$$

when T is the kinetic energy due to the relative motion of the electron and the atom.

Let us put $T = \dfrac{e^2}{C}$

then if T is expressed as V volts

$$C = 14{\cdot}4\times10^{-8}/V$$

and $\sin^2\theta = \dfrac{1}{1+\dfrac{d^2}{C^2}}$.

We see from this that θ will not be small unless d is considerably greater than C. Thus we may regard each electron in the atom as deflecting through considerable angles all electrons which pass within a distance C. They may, as far as collisions are concerned, be regarded as producing much the same effect as solid spheres of radius C. Now when the energy of the electrons is represented by 1 v., C is $14{\cdot}4\times10^{-8}$ centimetres. This is much greater than the distance between the electrons in the atom; thus the fields of influence of the different electrons in an atom will overlap, so that an increase in the number of electrons in the atom will not produce much effect on the scattering. On the other hand when T the energy of the electrons is so large that C, which is inverse proportional to T, becomes less than the distance between t electrons in the atom, the fields of influence of the differe electrons will not overlap and each electron will provide an add tional source of scattering, so that in this case the scattering w be proportional to the number of electrons in the atom.

With very slow electrons the scattering in most gases is i dependent of the speed but for argon and the heavier inert gas Ramsauer has made the very interesting discovery that very slo electrons are not scattered so much as those moving somewha faster, it is as if the atoms of these elements were more permeab to slow electrons than to fast.

Ionisation by Moving Ions.—When the moving systems are ion instead of electrons, the collision between them and the electron are collisions between masses of very different magnitudes, an in consequence a very much smaller fraction of the energy of th moving body becomes transferred to the electron than whe the colliding bodies have equal masses.

The amount of energy transferred to the electron when th moving body has a mass M_1 is equal to:—

$$\frac{4M_1M_2}{(M_1+M_2)^2}\times\frac{T}{1+\dfrac{4d^2T^2}{e^2E^2}\left(\dfrac{M_2}{M_1+M_2}\right)^2},$$

when M_2 is the mass of the electron and E the charge on th moving body. When, as in the case of the collision between a ion and an electron, M_2 is very small compared with M_1, thi becomes

$$\frac{4M_2}{M_1}\frac{T}{1+\dfrac{4d^2T^2}{e^2E^2}\dfrac{M_2^2}{M_1^2}}.$$

Thus, if Q is the ionising potential, the minimum value of T which will communicate this energy to the electron, is $\frac{1}{4}\frac{M_1}{M_2}$

For the smallest possible ion, an atom of hydrogen, $M_1/M_2=$ 1,700, so that the minimum energy that will enable an ion t ionise a gas by knocking out an electron from a molecule is equa to 425Q. Q for many gases is about 10 v.; thus a positive ion mus have at least energy represented by 4,250 v. to ionise the gas With more massive ions the energy required for ionisation woul be still greater.

An ion with a mass equal to that of a molecule of oxyge would not ionise unless its energy were greater than 136,000 volts Thus any ionisation by ions taking place in discharge tube where the potential difference is in general much less than thi value must be due to ions of the lighter elements, hydrogen o helium.

If the ion came into collision with the atom instead of with on of its electrons, it could, since its mass is comparable with tha of the atom, give up to this a large fraction of its energy, a ver much larger fraction than it is able to give to an electron. Inasmuch as it requires less work to dissociate a molecule into neutral atoms than to dissociate it into positively and negativel electrified ions, the result of such a collision is more likely to b the production of neutral atoms than of electrified ions.

An ion is, however, a much more complex thing than th simple charge of electricity which has, in the preceding considerations, been taken to represent the forces it exerts; and it may b that some strongly electronegative ions have such a strong attraction for an electron that when they pass through th molecule of a more electropositive element they are able t capture one of its electrons and carry it away with them. This type of ionisation would differ from the ordinary type, inasmuch as in it the electron is never free; this type produces negative ions, the other type negative electrons.

It is evident from the preceding considerations that except in very intense fields it must be the electrons and not the ions which produce ionisation by collision. Let us consider what are the chances of an electron acquiring sufficient energy in a uniform electric field; if the electron moved freely under the electric force X for a distance l it would acquire Xel units of energy.

e electron in its course through the gas will come into collision th other bodies; its path will be deflected, possibly reversed, d in moving against the electric field it may lose all the energy had previously acquired. Thus a collision of this type may stroy any ionising power given to the electron by the electric ld before the collision.

Let λ be the average distance passed over by an electron tween two collisions; then the chance of an electron moving rough a distance l without a collision is $\epsilon^{-\frac{l}{\lambda}}$, but if it moves rough a distance l it will acquire energy $=\mathrm{X}el$, hence the chance an electron acquiring energy equal to or greater than T is $\frac{\mathrm{T}}{\mathrm{X}e\lambda}$, and the chance that it should acquire energy between T d T+dT is $\frac{d}{d\mathrm{T}}\left(\epsilon^{-\frac{\mathrm{T}}{\mathrm{X}e\lambda}}\right)d\mathrm{T}$. If it possess this amount of energy e chance that it makes one ion per centimetre of path is $\frac{e^4}{\mathrm{T}^2}(\mathrm{T}/\mathrm{Q}-1)$; hence a, the chance that an electron should make e pair of ions per centimetre of path, is given by the equation

$$a = n\pi e^4\int_{\mathrm{Q}}^{\infty}\frac{d}{d\mathrm{T}}\left(\epsilon^{-\frac{\mathrm{T}}{\mathrm{X}e\lambda}}\right)(\mathrm{T}/\mathrm{Q}-1)\frac{d\mathrm{T}}{\mathrm{T}^2}$$

This may be written

$$a = \frac{n\pi e^4}{\mathrm{Q}^2}\mathrm{F}(\theta)$$

where $\theta = \mathrm{Q}/\mathrm{X}e\lambda$

and $$\mathrm{F}(\theta) = \theta\int_{\theta}^{\infty}\epsilon^{-x}\left(\frac{1}{x}-\frac{\theta}{x^2}\right)dx$$

Since λ for the same gas is inversely proportioned to the presre p, a will be of the form $nf(\mathrm{X}/p)$ where $f(\mathrm{X}/p)$ denotes a nction of X/p; and since n is proportional to the number of olecules per unit volume, a may be written as $pf(\mathrm{X}/p)$. hen the spheres described round the electrons with radius d

$$\text{where } d^2=\frac{l^4}{\mathrm{T}^2}\left(\frac{\mathrm{T}}{\mathrm{Q}}-1\right)$$

not overlap, n will also be proportional to the number of elecons in the molecule. The greatest value of d is $e^2/2\mathrm{Q}$; hence if , the distance between two electrons, is greater than $e^2/2\mathrm{Q}$ ere can be no overlapping; if D is less than this quantity, there ay be overlapping; since the value of d diminishes as the netic energy of the electron increases, n for very fast electrons ill be proportional to the number of electrons in the molecule.

Some of the electrons will by adhesion to a neutral molecule come negative ions. Let the chance of an electron doing so hile passing over 1 cm. be γp. If N be the number of electrons er c.c. at a place fixed by the co-ordinate x, then $\frac{d\mathrm{N}}{dt}+\frac{d}{dx}(\mathrm{NU})=$ te of increase of number of electrons per c.c., where U is the elocity of the electron parallel to x.

The number of electrons passing through the unit of area in nit time is NU. The new electrons produced by the passage of em through the unit volume is NUa, while NUγp will disapear; hence:—

$$\frac{d\mathrm{N}}{dt}+\frac{d}{dx}(\mathrm{NU})=\mathrm{NU}(a-\gamma p)+q \qquad (19)$$

here q is the ionisation due to external sources; when things are a steady state $d\mathrm{N}/dt=0$, and the solution of the equation, hen the electric field may be taken as constant from one elecode to another, is:—

$$\mathrm{NU} = \mathrm{C}\epsilon^{(a-\gamma p)x}-\frac{q}{a-\gamma p}$$

Most of the experiments on this subject have been made witht external ionisation; a supply of electrons has been obtained om the cathode, either by raising it to incandescence or by exsing it to ultra-violet light. In such cases $q=0$, and

$$\mathrm{NU} = \iota_0\epsilon^{(a-\gamma p)x} \qquad (20)$$

here ι_0 is the number of electrons emitted in unit time from the thode. Townsend, and Townsend and Kirby have determined the value of $a-\gamma p$ for various gases and over a considerable range of pressure. A series of these values for air are given in Table V.

TABLE V.

X = volts per cm.	Pressure (mm.)				
	·17	·38	1·10	2·1	4·1
20	·24	..	..	..	..
40	·65	·34	..	..	..
80	1·35	1·3	·45	·13	..
120	1·8	2·0	1·1	·42	·13
160	2·1	2·8	2·0	·9	·28
200	..	3·4	2·8	1·6	·5
240	2·45	3·8	4·0	2·35	·99
320	2·7	4·5	5·5	4·0	2·1
400	..	5·0	6·8	6·0	3·6
480	3·15	5·4	8·0	7·8	5·3
560	..	5·8	9·3	9·4	7·1
640	3·25	6·2	10·6	10·8	8·9

It will be seen that, when X is given, the increase in the number of electrons reaches a maximum for a particular pressure. From general reasoning this must be so, for if $p=0$ there will be no collisions to make fresh electrons, and if p is infinite the free path of the electrons will be so small that they cannot acquire sufficient energy to ionise the gas. Since a is of the form $pf\left(\frac{\mathrm{X}}{p}\right)$, and γ does not depend upon p, $a-\gamma p$ will be a maximum when

$$f\left(\frac{\mathrm{X}}{p}\right)-\gamma-pf^1\left(\frac{\mathrm{X}}{p}\right)\cdot\frac{\mathrm{X}}{p^2} = 0$$

or when $f\left(\frac{\mathrm{X}}{p}\right)-\gamma = f^1\left(\frac{\mathrm{X}}{p}\right)\frac{\mathrm{X}}{p}$ where $f^1(\mathrm{X}/p)$ denotes the differential coefficient of $f(\mathrm{X}/p)$ with respect to X/p. This equation determines X/p; hence the critical pressure will be proportional to the electric force. At this critical pressure $\mathrm{X}e\lambda$ bears to Q a ratio which depends upon the way in which the chance of an electron ionising by a collision depends upon the energy of the electron. If, for example, the chance were independent of this energy, provided the energy were greater than Q, the maximum current would be when $\mathrm{X}e\lambda=\mathrm{Q}$; this relation would not hold for other and more probable laws connecting ionising power with the energy, but we should expect that for any such law the ratio of $\mathrm{X}e\lambda$ to Q would neither be very large nor very small.

Since the electrons cannot begin to ionise until their energy is equal to Q, and to attain this energy they must pass through a distance $\mathrm{Q}/\mathrm{X}e$, it is clear that we ought in such an equation as (20) to write $x-\mathrm{Q}/\mathrm{X}e$ in place of x. If V is the potential difference between the plates, $\mathrm{X}=\mathrm{V}/d$, so that $x-\mathrm{Q}/\mathrm{X}e=x-d\mathrm{Q}/\mathrm{V}$ if Q is measured in volts. Thus in finding the current between two electrodes we must, if we use equation (20), write $d\left(1-\frac{\mathrm{Q}}{\mathrm{V}}\right)$ instead of d. Partsch (*Verh. d. Deutsch. Phys. Gesell.*, 14, p. 60) has shown that theory and experiment agree better by this change.

Ionisation Due to Radiation.—When rays of ultra-violet light of very small wave length or Röntgen rays which are vibrations with yet smaller wave length pass through a gas, the gas is ionised. The application of C. T. R. Wilson's expansion method (supra) to this case shows that the effect of the radiation is to expel from some of the gas an electron moving at a high speed. This electron ionises by collision the gas through which it passes and the majority of the ions are produced in this way. This is proved by the fact that on the Wilson photographs (*see* fig. 18) the drops of water which denote the presence of the ions are found to be arranged on lines starting from a molecule of the gas. For the ionisation to take place there must be some process going on by which the energy of the radiation can be concentrated on the minute volume occupied by an electron. The energy with which the electron is expelled from the molecule depends on the frequency of the radiation but not upon its intensity. Thus if the source of radiation be moved further away from the gas the number of high speed electrons ejected is diminished but the speed of those which are ejected is not affected. This result has led to the quantum theory of radiation, which supposes that radiant energy is made up into units, or at any rate is only communicable by such units, the unit of energy is proportional to ν the frequency of the radiation and equal to $h\nu$ where h is a constant called Planck's constant. On the C.G.S. system of units it is equal to $6{\cdot}55\times10^{-27}$. Since to expel an electron from a molecule requires the expenditure of Ve units of work when V is the ionising potential, if the electron is expelled by the radiation the energy available must be greater than Ve, hence ν the frequency of the light must be greater than the value V given by the equation

$$h\nu = Ve.$$

For example if the ionising potential of helium is 22·7 volts, helium will not be ionised by radiation unless the wave length of the radiation is less than 540 Ångstrom units.

It has been shown by Barkla that when the radiation is wholly absorbed in a gas the number of high speed electrons ejected is independent of the nature of the gas. Thus we may regard the production of a high speed electron as involving the destruction of a unit of radiant energy.

The connection between the wave length of the radiation and the amount of ionisation produced in gases of definitely chemical constitution is a most vital and important one which unfortunately has not received the attention it deserves. One most important question is whether the ionisation is an additive property, or not. If the chemical composition of the gas is represented by $A_xB_yC_z$ where A, B, C, are symbols representing chemical elements, and x, y, z, are the number of atoms of A, B, C, in the molecule, can the ionisation per molecule, when radiation of known frequency passes through the gas, be represented by

$$x(A)+y(B)+z(C)$$

where (A), (B), (C), are constants appertaining to the elements A, B, C, respectively? The evidence on the whole seems to be in favour of such a connection but the tests have not been very severe. The amount of ionisation due to radiation varies enormously with the nature of the gas. Thus the ionisation in hydrogen is so small that some observers consider that such as is observed is due to a trace of impurity. It is not comparable with that which occurs in gases like chlorine, sulphur, bromine, iodine and mercury vapours. It has been found that μ the absorption of radiation of wave-length λ estimated per molecule of the absorbing substance can be represented by formulae of the type

$$\mu = CN^p\lambda^q$$

where N is the atomic number of the absorbing substance and C a constant. The values of p given by different observers range from 2·5 to 4 and of q from 2·5 to 3. Values such as these indicate that the absorption and presumably the ionisation increase rapidly with the molecular weight. Thus if we take $p=3$ the absorption of the rays by an atom of iodine would be about 1,000 times that by an atom of carbon. For the same substance and different kinds of radiation, the ionisation increases as the cube of the wave length. Formulae of the type $CN^p\lambda^q$ hold over only a limited range of frequencies; the values of p and q appear to change when the wave length of the radiation passes through a value corresponding to that of a characteristic radiation of the absorbing substance. The graph representing the relation between the wave length and the absorption is of the type shown in fig. 6.

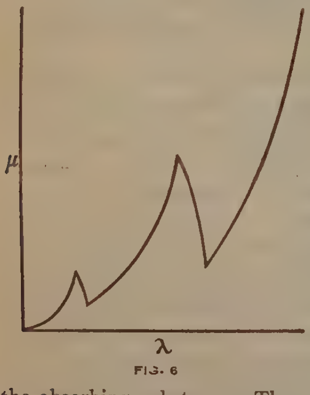

FIG. 6

It will be noticed that this curve differs very materially from the graph corresponding to the visible part of the spectrum. this part of the spectrum we may have very intense absorpti of light of a particular wave length, for example, the absorpti by mercury vapour of the line 2536 is so strong that the lig cannot pass through more than a few millimetres of the vapo at the pressure of one hundredth of a millimetre of mercury, a yet there is practically no absorption for lines whose wa length is either greater or less than 2536 by 1 Ångstrom un With radiation of the ionising type, on the other hand, thou the absorption comes in abruptly when the wave length fa below a critical value, it does not fall away abruptly when t wave length is still further diminished but decays according the λ^3 law. The application of this law leads us to expect th radiation between a certain range of wave lengths say from to 250 Ångstrom units would be exceedingly powerful ionisi agents. For the characteristic radiation given out by zi whose wave length is 1·4 Å, μ has been found to have the valu given in the second column of Table VI., the value of μ calc lated by the λ^3 law for radiation of the wave length 248 Å, f which the quantum is 50 v., is given in the third column.

TABLE VI. *Values of μ by the λ^3 law.*

Substance	$\lambda=1{\cdot}4$ Å	$\lambda=248$ Å
Carbon	4·26	$1{\cdot}8\times10^7$
Air at 0° C. & 760 mm.	$9{\cdot}1\times10^{-3}$	$4{\cdot}0\times10^4$
Mg	59	$2{\cdot}6\times10^8$
Al	105	$4{\cdot}6\times10^8$
Fe	1723	$7{\cdot}6\times10^9$
Cu	490	$2{\cdot}2\times10^9$

Since the radiation falls to $1/\epsilon$ of its value after passing throug a distance equal to $1/\mu$ we see that the radiation with the longe wave length would be practically completely absorbed by a laye of Al or Mg one molecule thick or by a layer of air one centimet thick at a pressure considerably less than that due to a tenth a millimetre of mercury. J. J. Thomson has shown by measurin the photo-electric effects produced inside the discharge tube b the radiation produced by the passage of the electric discharg through the tube that this radiation includes not only th visible part of the spectrum where the energy in the quantu is only some two or three volts, but soft Röntgen rays havin quanta between 20 and 100 volts. These rays as we have just see will be greedily absorbed by the gas and produce intense ionisa tion. A large part of the ionisation in the tube is probably du to these rays which are excited by the passage of cathode an positive rays through the gas and by their incidence on the ele trodes and on the walls of the discharge tube.

Spark Discharge.—The production of ions by moving electro will not by itself explain why a current of electricity can b maintained through a gas by an electric field when all oth sources of ionisation are excluded. The electrons are continuall being driven towards the anode, and unless there is some sourc of supply near the cathode the ionisation and therefore th current will rapidly come to an end. One way in which th electrons could be supplied by the action of the electric fiel would be by the positive ions which strike against the cathod communicating so much energy to the electrode that it is raise to incandescence. Since an incandescent metal gives out larg quantities of electrons there will be a continuous supply o electrons from the cathode, which will ionise the gas and produc fresh positive ions to strike against the cathode and keep it hot This is what happens in the arc discharge when the cathode is kept in a state of incandescence by the discharge. In this case there is a large amount of energy put into the arc. There are however, other forms of continuous discharge where the cathode does not become incandescent, so that there must be other ways in which the supply of electrons is maintained. From what we know about ions there are several ways in which this might occur

It has been found by experiment—[Füchtbauer, *Ann. der Phys.*, 23, p. 301 (1907); Saxen, *Ann. der Phys.*, 38, p. 319 (1912); Baerwald, *Ann. der Phys.*, 41, p. 643 (1913); 42, p. 1207 (1913)]— that electrons are emitted from metals when these are bombarded by high speed positive ions even though the metal is not raised to

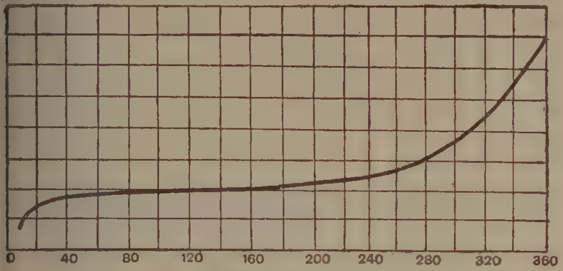

FIG. 7

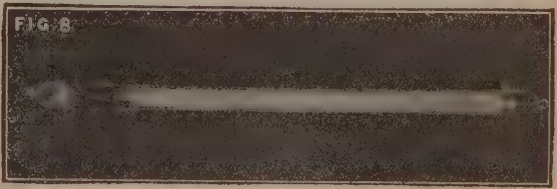
ncandescence. According to Baerwald the emission of electrons from metals bombarded by positive hydrogen atoms does not become appreciable until these have an amount of energy exceeding that represented by 900 volts. Again positive ions ionise gas through which they pass. This was shown by McClelland, who found that the relation between the potential difference and the current from a hot wire anode surrounded by gas at low pressure was represented by a curve like that shown in fig. 7. The hot wire furnishes positive ions as well as negative ones, and he curve shows that fresh ions are formed when the potential difference is greater than about 200 volts. This is a much greater potential difference than that needed to produce ionisation by electrons, but it is smaller than would be expected by the considerations given above. As it requires less work to eject an electron from a metal than from a molecule, we should expect that f 200 v. ions could eject electrons from a gas through which they pass they would be able to do so from a metal against which they strike, but from Baerwald's experiments much more energy than 200 v. is required for this purpose. In McClelland's experiments the ionisation might have been into positive and negative ons rather than into positive ions and electrons; before the negative ions could be efficient for ionisation by collision they would have to undergo further dissociation into electrons and uncharged molecules. Curves similar to that in fig. 6 have also been obtained by O. W. Richardson. Pawlow (*Proc. Roy. Soc.*, A. 90, p. 398) and also Franck and E. v. Bahr (*Verh. d. Deutsch. Phys. Ges.*, 16, p. 57, 1914) came to the conclusion from their experiments, that ionisation was produced by positive ions even when their energy did not exceed a few volts; indeed they could not get any evidence of a minimum to the ionising voltage. Horton and Davies (*Proc. Roy. Soc.*, 95, p. 333) could not detect any ionisation in a gas by positive helium ions when the energy was due to 200 volts. They ascribe the ionisation observed by Pawlow, Bahr and Franck to photo-electric effects; they consider, however, that positive helium ions can liberate electrons from a metal against which they strike if their energy exceeds 20 volts. Baerwald considers that it requires an energy measured by 900 v. before positive ions can liberate electrons from metals.

There are thus at least four methods by which the supply of electrons near the cathode necessary to maintain the discharge can be obtained. The gas near the cathode may be ionised by positive ions or by radiation, or the cathode itself may emit electrons under the impact of positive ions or by the incidence of radiation.

When the gas is at a low pressure, the appearance of the discharge has well-marked characteristics which may throw light on the method by which the electrons are produced and the place from which they start. The discharge near the cathode is represented in fig. 8; in contact with the cathode there is a velvety glow, then a space comparatively dark called the cathode dark space; this joins on to a brightly luminous region called the negative glow; passing through this region, and making themselves evident by the luminosity they excite when they strike against the glass wall of the vessel in which the gas is contained, are the cathode rays. These have been shown to be electrons moving with high velocity. These electrons have been liberated by the action of the electric field and have acquired their velocity under the action of that field. The velocity of the cathode rays has been measured, and it has been found that the majority of them have the same velocity. This shows that they must have all fallen through the same potential. They would do this if they all started from the cathode itself, but if they had originated by the ionisation of the gas in the dark space in front of the cathode some would have started from one place and some from another, and they would have acquired different velocities. This is strong evidence in favour of the cathode itself being the primary source of the electrons which maintain the discharge. When a supply of electrons is produced by processes taking place at the cathode, ionisation by collisions of electrons with the molecules of the gas is sufficient to maintain the discharge through the interval between the negative glow and the anode. This interval, as will be seen from fig. 8, is made up of a short part next the negative glow in which there is comparatively little light, called the Faraday dark space, and then a long uniform portion reaching right up to the anode. Unless the pressure is very low or the spark very short this portion, which is called the positive column, forms by far the larger part of the discharge. The discharge here will be maintained if the rate at which electrons are produced by collision is equal to the number lost by recombination. When this is the case, equation (19) gives $\alpha=\gamma p$, or, since α is of the form $pf\left(\frac{Q}{Xe\lambda}\right)$



$$f\left(\frac{Q}{Xe\lambda}\right)=\gamma$$

thus $Xe\lambda=cQ$ where c is a quantity which does not depend upon the pressure or strength of the field; as λ is inversely proportional to the pressure, this equation is equivalent to $X=c_1p$, when c_1 is a quantity which will depend on the nature of the gas and possibly on the intensity of the current. If l is the length of the positive column the difference in potential between the anode and the end of the positive column next the cathode is lX, *i.e.*, c_1pl.

Between the cathode itself and the negative glow there is a fall of potential, called the cathode potential fall, which, when the current carried by the discharge is not large, is independent of the current and the pressure of the gas; it depends upon the nature of the gas and the material of which the electrodes are made. If V_0 is the cathode fall, then (neglecting the change in potential in the negative glow and the Faraday dark space, which has been found by experiments to be very small) V, the potential difference between the anode and cathode, will be given by the equation

$$V = V_0+c_1lp \qquad (21)$$

It is assumed that the length of the spark is greater than that of the dark space D; at pressures comparable with that of the atmosphere, D is a very small fraction of a millimetre, but at the low pressures which can easily be obtained in highly exhausted vessels D may be several centimetres. It is to be noticed that V is a linear function of lp, and lp is proportional to the mass of gas between the electrodes; hence as long as the mass of gas between the electrodes remains unaltered the potential difference required to maintain the spark will be constant. This law, which was discovered by Paschen in 1889 as the result of a long series of experiments, is known as "Paschen's law." It has been found to be in agreement with the very numerous investigations which have been made on the potential difference required to produce a discharge in an approximately uniform electric field such as that which exists between two slightly curved electrodes.

The relation (21) does not give any indication of the relation between the potential difference and the spark length when the latter is exceedingly small. When the spark length falls below a critical value which is inversely proportional to the pressure, and which in air at atmospheric pressure is about ·01 mm., the spark potential increases rapidly as the spark length diminishes; this was first observed by Peace. A simple way of demonstrating it is to use slightly curved electrodes and to observe the path of the spark as these are brought closer together. Until the electrodes get very close together the spark passes along the shortest line between them, but as they approach each other a stage is reached where the spark no longer passes along the shortest line but goes to one side, taking a longer path, showing that it is easier to produce a long spark than a short one. The relation between the potential difference and the spark length for several gases has been determined by Carr, who finds that Paschen's law that the potential difference depends only on *pl* is also true for very short sparks; Paschen's own experiments were made with sparks considerably longer than the critical value. Fig. 9 represents Carr's results for the relation between V and *pl*. The results of Carr's and Strutt's (Lord Rayleigh's) experiments for the minimum spark potential, and the value of *pl*, at which it occurs, are given in the following table:—

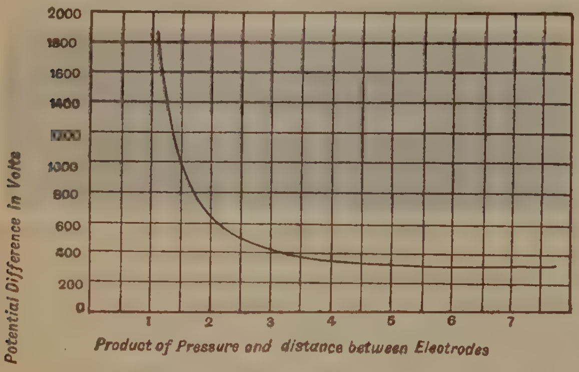


FIG. 9

TABLE VII.

Gas	Minimum Spark Potential in volts	*pl*
Air	341 S[1]	5·7
Nitrogen	251 S	6·7
Oxygen	455 C	..
Hydrogen	302–308 S 278 C	14·4
Carbonic acid	419 C	5·1
Sulphur dioxide	457 C	3·3
Nitrous oxide	418 C	5
Sulphuretted hydrogen	414 C	6
Acetylene	468 C	..
Helium	261 S	35

[1] S = by Strutt; C = by Carr.

The curves are very flat in the neighbourhood of the minima, so that the critical values of *pl* may be subject to considerable errors. Strutt found that even very small traces of impurity produced very large increases in the values of the minimum spark potential in nitrogen and helium; these are gases where, as we have seen, such traces produce large diminutions in the mobility of the negative ion. The existence of a minimum for the spark potential and a critical spark length follows from the view that the self-sustained discharge is maintained by radiation produced by electrons or positive particles. The condition for the self-sustained discharge is that an electron in its passage between the electrodes exerts some ionisation effect which produces another electron to succeed it. If V is the potential between the plates, the energy given to the electron is Ve. Let the amount of this converted into radiation be βVe; if μ is the coefficient of absorption, d the distance between the plates, then when d is small the number of ions produced by the electron will be $\beta\mu dVe$. If the electron is to provide a succession this must be equal to unity that

$$V = \frac{1}{\beta\mu e d},$$

so that the potential difference varies inversely as $1/d$ and infinite when d vanishes. Since μ is proportional to the pressu of the gas we see that V will depend upon pd so that Pasche law is fulfilled.

The mechanism we have hitherto considered involves t ionisation of the gas between the electrodes, and no spark cou pass across a vacuum. There are, however, other methods which a discharge might do this. For suppose there was a str electron between two parallel electrodes in a vacuum; then und the action of the electric field it would be driven against t anode; by the impact Röntgen radiation would be generate which would fall on the cathode, and if it were intense enou to liberate one electron from the cathode the original electr would be replaced and the passage of negative electricity fro the cathode to the anode would be repeated. From these co siderations it is probable that even the highest vacuum would n act as a perfect insulator for very intense fields.

The linear relation $V=V_0+c_1lp$ has been obtained on t assumption that the direction of the electric force was the sam in all parts of the field; this is only true when the dimensions the electrodes are large compared with the distance betwe them. The potential difference required to produce a spark a particular length depends upon the size of the electrod between which the spark passes, and is not a linear function of l where p is the pressure and l the spark length, unless l is sma compared with the linear dimensions of the electrodes. If the are spheres, the spark potential will depend upon their radi and for small spheres may be considerably less than for larg ones. Thus, for example, the spark potential in air for a fiv centimetre spark is 26,000 v. for electrodes ·5 cm. in diamete and 105,000 v. when the diameter of the electrodes is 5 cent metres.

In this connection it may be noted that, if the electric field sufficiently intense at any place to produce there a local supply ions, these may redistribute themselves between the electrode and by their electrostatic action produce a change in the distribution of the electric force more favourable to the passage the spark than that prior to the production of the ions. T illustrate this, take the very simple case when the electrodes ar two parallel plates: if there are any ions available these ma distribute themselves so that the force between the plates is n longer uniform. Thus let us suppose that there are enoug positive ions to congregate round the cathode in sufficient numbers to produce within the distance of the "critical spark length" or thickness of the cathode dark space, a difference of potentia equal to the minimum spark potential. This would ensur a continual emission of electrons from a place in front of th cathode, and even though the electric field from this place to th anode were too feeble to give an electron enough energy to ionis the gas, the electrons coming from the cathode would be able t carry a small current, though this part of the discharge migh not be luminous. The ions here would be all of one sign, so tha the electric force will increase up to the anode. If the curren is gradually increased, the place where the electric force wil first rise to the value necessary to make the electrons ionise wil be close to the anode. When this occurs a supply of positive ion will start from the anode and move towards the cathode, accompanied by luminosity close to the anode and very faint luminosit through the rest of the tube. The introduction of the positiv ions into the region between the anode and cathode will diminish the retarding effect of the negative space charge which existe in this region, so that the current will increase. This increase i current will again increase the ionisation at the anode, and thus the supply of positive ions. In this way there might be a supply of electrons coming from the cathode, and of positive ions from close to the anode, which will maintain the current in spite of the fact that between these places there is a region where the electric rce is below that required to produce ionisation by collision, and ie potential difference between the electrodes less than that lculated on the supposition that the electric force was uniform om one to the other. We should expect from these considera- ons that, if the electric force at any point were intense enough produce ionisation by collision, some discharge would take ace.

Russell (*Phil. Mag.*, 6, xi., p. 237) states that the results of the fferent experiments made on the potential difference required to roduce sparks of various lengths between spherical electrodes of arious radii are in good agreement with the rule that the dis- narge takes place in air at atmospheric pressure if the electric rce at any point in the field before discharge begins is as great 37,000 v. per centimetre. This value agrees well with that quired to make electrons produce, in air at atmospheric pressure, ther ions by collisions.

The curious lag observed by Warburg between the application f the potential difference and the passage of the spark, which hen the applied potential is only a very little greater than that quired to produce the spark may amount to several seconds, naturally explained as the time needed by the ions to dis- ribute themselves so as to produce the distribution of potential quired for the discharge.

The discharge of electricity from points affords a good illus- ration of the preceding considerations. Suppose that the elec- rodes are a needle point and a plane. When the discharge first egins the only place where any light is to be seen is close to the oint; the current between the electrodes is very small; as the otential difference increases a stage is reached where light begins o appear close to the plate, the space between the point and plate eing quite dark. This stage is marked by a large increase in the current. With further increase in current the luminosity extends nto the gas and ultimately stretches from one electrode to nother.

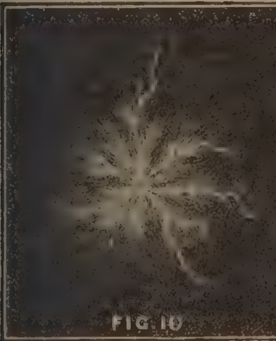

FIG. 10

FIG. 11

The potential required to start the discharge is less where the oint is negative than when it is positive. This is what might e expected, for to maintain the discharge from the negative oint there must be (1) ionisation of the gas by the outgoing elec- rons, and (2) liberation of electrons by the incoming positive ons, while when the point is positive there must be (1) ionisation f the gas by outgoing positive ions, and (2) liberation of positive ons by the impact of incoming electrons; as the process is not he same as for the negative point we should expect that there would be a difference between the potentials. It is not only the otential difference which is affected but the type of discharge. This can be shown by allowing the point discharge to pass in the neighbourhood of a photographic plate. Beautiful figures are found on developing the plate, and the character of these is different according as the point is positive or negative. Figures 10 and 11 represent discharges from positive and negative points respectively.

The discharge from a negative point is in some gases very much influenced by the purity of the gas; thus Warburg found that the discharge from a negative point in nitrogen increased about 50 times by removing the last trace of oxygen from the nitrogen, though this had little or no effect upon the discharge from a positive point. This can be accounted for by the discovery of Franck and Hertz that in very pure nitrogen the electron does not unite with the molecule and become a negative ion and has therefore a very high mobility. This is true for the inert gases as well as for nitrogen, and Przibram has shown that the difference between the discharges from positive and negative points is exceptionally large in these gases.

Electrical Wind.—The electrified ions' starting from the point in a point discharge sets the gas in the neighbourhood of the point in motion producing a current of air, called the "electrical wind." The momentum gained by the air is lost by the point, so that there is a backward force acting on the point, which has often been measured. This force, as well as the electrical wind, is smaller when the point is negative than when it is positive; this difference is especially marked at pressures low enough to make the negative ion have an abnormally large mobility.

Relation between Potential Difference and Current.—The potential difference required to maintain a discharge will depend upon the current passing in the discharge. The relation between the current and the potential difference for discharge through gases is often a very complicated one. We should expect that this would be so, for in the spark discharge, for example, the potential difference is made up of the cathode fall of potential (this increases with the current when the current is large) and a uniform force along the rest of the discharge, and this force in many cases diminishes as the current increases. Thus whether increases of current produce an increase or decrease in the potential difference will depend on the relative contributions of these two parts.

A curve whose ordinates are the potential difference between the electrodes and the abscissae the current through the gas, is called the "characteristic curve" for the discharge (see fig. 12). From such a curve it is possible to find the current sent through a gas by a given external electromotive force. Suppose that the current sent through a gas by a battery of cells of electromotive force E_0 is required. If R is the resistance of the curves connecting the battery with the electrodes in the gas, then $E_0-R\iota$ is the potential difference between the electrodes in the gas, and one relation between this potential V and the current is represented by the straight line $V=E_0-R\iota$. The other relation is that represented by the characteristic curve; the values of the current through the gas and the potential difference between the electrodes will be determined by the points of intersection of this straight line and the characteristic curve. Unless the straight line cuts the curve there can be no discharge through the gas; on the other hand, the straight line may cut the characteristic curve in more than one point, indicating that there is more than one type of discharge. Some of these types may, however, be unstable and thus impossible to realise. Thus, for example, if the current is increased by $\delta\iota$ the difference of potential given by the battery between the electrodes is diminished by $R\delta\iota$;

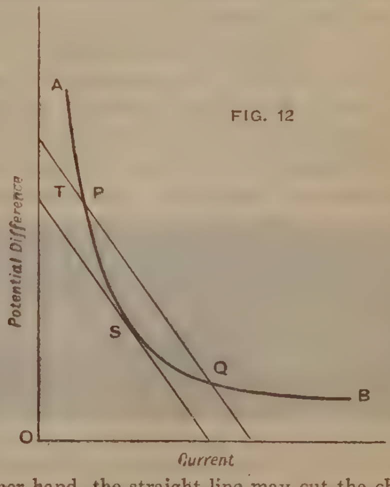

FIG. 12

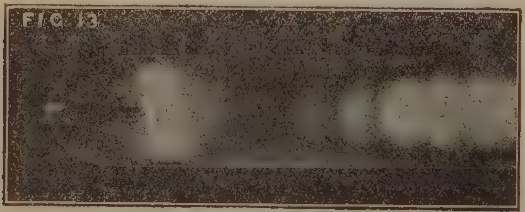
if V is the potential difference between the electrodes required to send a current ι through the gas, then when the current is increased by $\delta\iota$, the increase in the potential required is $\frac{dV}{d\iota}\delta\iota$; thus unless $\frac{dV}{d\iota}\delta\iota$ is less than $-R\delta\iota$, or $-\left(\frac{dV}{d\iota}+R\right)\delta\iota$ be positive, the diminished potential supplied by the battery will not be sufficient to maintain the increase in the current; this increase will stop, the current will return to its original value, and the discharge will be stable; thus if $R+\frac{dV}{d\iota}$ is positive the discharge will be stable. If, however, $R+\frac{dV}{d\iota}$ is negative the fall in potential required to maintain the increased current is so great that, in spite of the diminution of the potential difference supplied by the battery, the residue is great enough to maintain the increased current, the increase in the current will continue, and the discharge will be unstable. Thus the condition for stability is that $R+\frac{dV}{d\iota}$ should be positive, a result first given by Kaufman. This result is equivalent to the condition that for stability the straight line must, at the point where it cuts the characteristic curve, fall more steeply than the tangent to the curve at that point. Thus if APQB, fig. 12, the characteristic curve and the right line cut at PQ, the type of discharge represented by P is unstable, and that by Q stable. Keeping the electromotive force at the battery constant and increasing the resistance will make the straight line steeper, and Q will move to the left and the current through the tube will decrease; when the line gets so steep that it touches the curve at S, the minimum value of the current consistent with the maintenance of this type of discharge by the electromotive force supplied by the battery will be reached, and any further diminution of the current will result in the extinction of this type of discharge. It is a well-known fact that the existence of most types of luminous discharges requires the current to be above a certain critical value which depends upon the external force. The electric arc is perhaps the most familiar example of this. As the characteristic curve for the arc discharge is a rectangular hyperbola represented by the equation $V=a+\frac{b}{\iota}$; we can easily show that if the external electric force is E, the maximum resistance which can be introduced into the circuit without extinguishing the arc is $(E-a)^2/4b$, and the smallest current compatible with the existence of the arc $2b/(E-a)$. For any stable type of discharge we see that an increase in the external electromotive force will result in an increase of current; at a point corresponding to an unstable condition it produces a diminution.

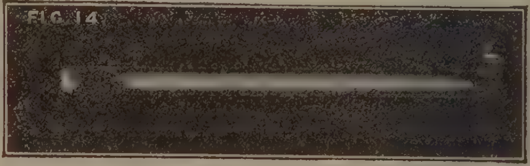
Structure of the Discharge.—The structure of the discharge at atmospheric pressure is on so fine a scale that its details can only be made out with difficulty; as the pressure is reduced the scale gets larger and larger, until, when the pressure is reduced to that due to a millimetre or so of mercury, the details of the structure become very conspicuous. The appearance of the discharge at such a pressure is shown in fig. 13, and we see that it is built up of several constituents of very different types. We have already, when considering the spark discharge, given a general description of some of them; there are, however, some features which require further discussion.

FIG. 13



Starting from the cathode, we find a thin layer of luminous gas, the colour of which depends on the kind of gas through which the discharge is passing. In most gases the light appears to reach right up to the cathode, but in hélium Aston has shown it separated from it by an exceedingly thin dark space. This minous layer is sometimes called “ Goldstein's first layer ”; n to this we have a region where there is comparatively lit luminosity called “ Crookes' dark space,” the boundary of t space being approximately the surface traced out by normals the surface of the cathode of constant length. The thickness the dark space, which is of the order of the critical spark leng depends upon the pressure of the gas, varying approximately the reciprocal of the pressure; for air at the pressure of 1 mm. mercury the thickness of the dark space is about 2 mm. so th at atmospheric pressure the thickness would not be much mo than about 1/400 of a millimetre. If the pressure remains co stant and the current through the tube is increased, the thickn of the dark space remains unaltered until the current is lar enough to cover the whole of the cathode with the luminous glo after this stage is reached any further increase in the curre causes a diminution in the thickness of the dark space. Starti from the boundary of the dark space there is a brightly lumino region called “ the negative glow.” The function of the par of the discharge from the cathode to the negative glow is produce the supply of electrons from the neighbourhood of t cathode necessary to keep the discharge going. The dimensio of this part of the discharge are independent of the distan between the cathode and anode; at very low pressures this pa may occupy a length of several centimetres, but at atmospher pressure they are crowded into a very small fraction of a mil metre and as far as length goes occupy a negligible portion of t sparks at such pressures. The Crookes' dark space, though appears dark in contrast to the negative glow, is not devo of luminosity; indeed Seeliger, who has made a spectroscop examination of the dark space, finds that there are some line such as the Balmer series lines, which are almost as bright in t dark space as in the negative glow. But many lines are muc stronger in the negative glow than in the dark space.

FIG. 14



Beyond the negative glow there is another comparatively dar region called the “ Faraday dark space”; the length of this very variable even when the pressure is constant, as it is sensiti to any change in current. Beyond this and reaching right up t the anode is a luminous column called the positive column. Th luminosity in some cases is fairly uniform in intensity, but whe the pressure and current are between certain limits this colum may exhibit remarkable alternations of dark and bright space called striations, such as are shown in fig. 14. Under some ci cumstances a dark space round the anode has been detected b several observers.

When the distance between the electrodes is considerable an the pressure not very low, the positive column forms by far th greater part of the discharge; thus at atmospheric pressures al but a fraction of a millimetre of the discharge next the cathod will consist of the positive column.

Distribution of the Electric Force Along the Discharge.—Th electric force is very large indeed in the part of the dark spac next the cathode, but diminishes rapidly towards the negativ glow. In the negative glow itself it is smaller than in any othe part of the discharge; passing the negative glow, the electric force increases in the Faraday dark space, until the positive column is reached. When the positive column is of uniform luminosity the electric force in the column is constant until quite close to the anode, when there is an abrupt change of potential of about 20 volts, called the anode fall of potential. When the positive column is striated, the alternations of luminosity in the positive column are accompanied by alternations in the intensity of the electric force, the maxima of the electric force occurring the bright parts of the striae; the minima at the dark. From equation $\frac{dX}{dx} = 4\pi\rho$, where X is the electric force in the direc- n of x and ρ the density of the electrification, we see that there n excess of positive electricity in the cathode dark space and of gative in the Faraday dark space; in a uniform positive column re is no appreciable excess of electricity of one sign over that the opposite, while in the striated positive column there is an ess of negative electricity on the cathode side of a bright t of a striation and of positive on the anode side.

athode Fall of Potential.—Until the glow next the cathode vers the whole of the electrode the difference of potential be- een the cathode and the negative glow is constant, depending the gas and the material of which the cathode is made, but ng independent of the pressure of the gas and the strength the current. This constant difference of potential is called " cathode fall of potential," and there is evidence to show t it is equal to the minimum potential that can produce a ark through the gas. Its value, for different gases and different ctrodes is given in the following table, due to Günther- aulze:—

TABLE VIII.

	K	Na	Mg	Al	Zn	Fe	Pb	Cu	Ag	Aa	Pt

Further light is thrown on the origin of ionisation in gases by the dy of the distribution of electric force in the neighbourhood the cathode. Aston has shown that at low pressures the force the neighbourhood of the cathode is a linear function of the stance from the cathode, so that if V be the electrostatic point a point distant x from the cathode

$$\frac{dV}{dx} = C(d-x) \tag{22}$$

en C and d are constants. If ρ is the density of the electrifica- n at the point x: $4\pi\rho = d^2V/dx^2$, hence for this law of force s constant. We have to consider what law of ionisation is com- tible with this result. It can be shown that to make ρ constant e ionisation must be independent of the distance from the thode, a result which seems much more probable if the ionisa- n is due to radiation than if it were mainly due to ionisation collision. We see from equation (22) that dV/dx vanishes en $x = d$. This is the place where the negative glow begins. e potential difference between the cathode and the boundary the negative glow is called the cathode fall of potential and is a antity of great importance, of which many measurements ve been made which are given in Table VIII. The cathode fall potential depends on the nature of the gas and of the electrodes t is independent of the pressure.

The consequences of the hypothesis of ionisation by radiation e in fair agreement with the results of experiments; they are as lows:—

The normal cathode fall of potential is independent of the essure of the gas.

The thickness, d, of the dark space is inversely proportional to e pressure.

The cathode fall of potential V is connected with I the density the current carried by the positive ions by the relation:—

$$V^{\frac{3}{2}} = \left(\frac{M}{2e}\right)^{\frac{1}{2}} \pi^2 I d^2 \tag{23}$$

ere M is the mass of a molecule of the gas.

The cathode fall of potential is on this view equal to the allest potential difference that can produce a spark through e gas and the thickness of the dark space at any pressure is the gth of the spark which at that pressure passes with the nimum potential difference.

We see from equation (23) that in order to produce the discharge a definite current density as well as a definite potential difference is required. This density, for a flat electrode, is as we see from equation (23) inversely proportional to d^2 and therefore directly proportional to the square of the pressure.

The values of V and I at a pressure of 1 mm. of Hg for plane cathodes (1) of aluminium, (2) of iron, for different gases have been determined by Günther-Schulze (*Zeit. für Physik*, 20.1).

TABLE IX.

Gas	Aluminium		Iron	
	I(am/cm²)	V. volts	I(am/cm²)	V. volts
He .	1·07	153	1·187	161
Ne .	1·81	145	2·000	153
Ar .	14·07	150	15·5	166
N .	38·4	215	42·3	256
H .	9·0	192	9·96	250
O .	54·7	250	60·6	326

V depends on the nature of the electrode as well as upon the gas. Günther-Schulze's experiments indicate that V can be expressed approximately in the form:—

$$V = 35{\cdot}5\epsilon + a$$

where a is a quantity depending on the gas and ϵ, a quantity called the electrochemical normal equivalent, which is given in the last row of Table VIII.

The values of a in volts for different gases are He, 175; Ne, 169; Ar, 174; N, 265; H, 290; O, 350. The preceding values refer to what are called the normal values when the current flowing through the tube is not large enough to cover the whole cathode with glow, so that an increase in the current may occur through an increase in the area over which the current is spread and not from an increase in the mean density of the current.

Günther-Schulze gives the following empirical expression for the dark space, d

$$pd = (\text{constant})\,\lambda V_1$$

when p is the pressure, λ the free path of the molecule at atmospheric pressure, and V_1 the ionising potential of the gas. When the current is so great that the whole electrode is covered with glow V, I and d are no longer constant; the cathode potential fall increases and the dark space diminishes as the current I increases. According to Aston's experiments (*Proc. Roy. Soc.*, 86, p. 178), the following relations exist between these quantities:—

$$d = \frac{A}{p} + \frac{B}{\sqrt{I}}$$

$$V = E + \frac{F\sqrt{I}}{p}$$

Here p is the pressure and A, B, E, F constants.

As the current increases the values of V may increase to many thousand volts and thus be hundreds of times the normal value. According to Aston there is no sudden jump in potential at the cathode itself, some observers (*e.g.*, Westphal) have thought that such a drop occurred and that it amounted to a considerable fraction of the whole potential fall.

Though in many gases and especially in oxygen there is a very sharply defined boundary to the dark space, it must not be thought that no radiation comes from the dark space; it is only for certain types of radiation that the radiation from the dark space is absent. Thus for the type of radiation which is instrumental in producing ionisation, there is no discontinuity in the radiation as we pass across the boundary of the dark space, and Seeliger and his co-workers have shown that even for visible radiation the change in intensity on crossing the boundary depends to a great extent on the wave-length of the light. The electrical conditions inside the dark space differ very much from those outside; inside we have a great preponderance of positive ions over electrons, while outside the two are equal; again outside the density both of free electrons and of positive ions is much greater than inside, and there is recombination of electrons and positive ions outside and not inside. It is not surprising therefore that radiation produced outside the dark space should differ substantially from that produced inside.

Anode Fall of Potential.—Unlike the cathode fall of potential which is spread out through a length equal to the thickness of the dark space, the anode fall as Skinner has shown occurs quite abruptly so far as it can be tested by experiment. If this fall took place in molecular distances the electric attraction might be sufficient to drag positive ions out of the electrode itself. By using a cathode heated to incandescence, and therefore emitting a plentiful supply of electrons, we can reduce the cathode fall of potential to a small fraction of its normal value; we cannot, however, with a luminous discharge get rid of the anode fall; thus in the arc discharge the anode fall of potential is greater than the cathode fall. Matthies has shown that, in chlorine, bromine and iodine, the anode fall of potential may rise to hundreds of volts, that in air or hydrogen being only about 18 volts. Reichenheim and Gehrke utilised this fact to get positive ions of sodium and potassium projected with great velocity. They made the anode of a mixture of the halogen salts of these metals and graphite, and worked at a very low pressure; under the action of the discharge the halogens were liberated from the anode, and the large anode fall they produced was sufficient to project sodium and potassium ions from the anode with great velocity; this stream of positive ions constitutes what is known as "anode rays."

The electric force in the positive column is a linear function of the pressure; it depends slightly on the diameter of the tube through which the discharge is passing; it also depends on the current through the tube; in most cases, though not invariably, an increase of current produces a decrease in the electric force. The condition determining the electric force in the positive column is that it should give to an electron during its free path the amount of energy that will enable the electrons to produce by collisions as many ions per second as are lost during the same time by recombination.

Striated Discharge.—The form of discharge when the positive column is striated is so beautiful and remarkable that it has attracted a great deal of attention. To get this type of discharge the current and pressure must be within certain limits. The striations are developed more readily in mixtures of gases than in a pure gas; in fact some physicists have advanced the view that they could not be obtained in an absolutely pure gas. There is no doubt, however, about their occurrence in gases in which great attention has been paid to purification. Nörbeck could not get them in pure nitrogen or pure helium, though they were conspicuous as soon as a trace of impurity was admitted. Nitrogen and helium are gases in which, when pure, the carrier of negative electricity is always an electron; in these gases the electron does not join on to a molecule and become a negative ion. Spottiswoode found that, in some cases when the positive column showed no signs of striation when observed in the usual way, striations moving rapidly down the tube could be seen when the discharge was observed after reflection in a rapidly rotating mirror. Aston and Kikuchi, who have studied this effect in neon and helium, are of opinion that the striations are moving in these gases with the velocity of sound; it must be remembered, however, that the velocity of sound in many gases is of the same order as the velocity of a positive ion under the electric forces in the positive column, so that this result does not necessarily prove that the moving striations are analogous to sound waves.

The distance between the striations increases as the pressure diminishes (in hydrogen the distance is inversely proportional to the square root of the pressure); it depends upon the size of the tube: the striations are nearer together in narrow tubes than they are in wide. The distance between the striations also depends upon the current. When several gases are in the tube, spectroscopic observation of the bright parts of the different striations shows that we may have one set of striations corresponding to one gas, another to another, and so on. Thus Crookes observed in a tube containing hydrogen three sets of striations, one set red, another blue and a third grey; the spectroscope showed that the first was due to hydrogen, the second to mercury vapour and the third to hydrocarbons. The striations are often curved their concavities turned to the anode.

To get a general idea of the causes which might give ri stratifications, let us consider a case where the current is ca entirely by electrons, the positive ions being regarded as movable in comparison with the electrons. Let us consid stream of electrons emerging from the negative glow; t electrons will have very little energy and will be unable to io the gas. The electrification beyond the negative glow on anode side will be due to electrons and will be negative so the electric force will increase towards the anode. As the ele force increases the energy of the electrons also increases, unt is sufficient to enable the electron to ionise the gas and proc positive ions and electrons; the increase in the number of will check the rate of increase in the electric force. The con tion between the ionisation and this rate of increase is in the we are considering represented by a very simple equation. if n and m represent respectively the number of negative positive ions per unit volume, X the electric force, and x distance from the cathode

$$\frac{dX}{dx} = 4\pi(n-m)e \qquad ($$

If the current ι is carried, as we have supposed, by the electro $neu = \iota$, where u is the velocity of the electron. If we neglect current carried by the positive ions, then when things h reached a steady state the number of positive ions produced any region per second must equal the number which disapp owing to recombination. Hence, if q is the rate of ionisation the coefficient of recombination, $q=\alpha mn$ or $m=q/\alpha n$; and (24 equivalent to

$$\frac{dX}{dx} = \frac{4\pi\iota}{eu} - \frac{4\pi qeu}{\alpha\iota} \qquad ($$

Thus as long as q vanishes, dX/dx is positive, but as soon a becomes finite the rate of increase of X will be retarded; X increases q increases, and when $e^2qu^2=\alpha\iota^2$, dX/dx will vanis but though X reaches its greatest value at this point, the valu of u and q, which depend on the energy acquired by the electro will continue to increase beyond it. For the energy acquired an electron depends on $\int Xdx$, taken over a distance measur by the free path of the electron; at low pressures this may be centimetre or more, and the place where $\int Xdx$ is a maximu will be beyond that where X is a maximum by a length of th order. Thus after X has reached its maximum u and q will i crease and dX/dx will become negative, so that X will diminis the diminution in X will ultimately produce a diminution $\int Xdx$ and also in u and q; the rate of decrease will slow down; will attain a minimum, and begin to increase again when simil changes will be repeated. Thus the curve which represents th relation between X and x will resemble fig. 15, where the cathode is on the left, giving alternate maxima and minima for the value of X; and $\int Xdx$, the energy acquired by an electron, will vary periodically along the path of the discharge. Ther are two values of this energy which are of special importance i connection with discharge through gases, one the ionising potenti we have already referred to, the other, sometimes called th "radiation potential," is the energy which the electron must pos sess to make the gas luminous. The radiation potential is les than the ionising potential, and electrons with energy betwee these potentials will make the gas luminous but will not ionis it. Thus the molecules of the gas will give out light but will no be charged. When the energy of the gas exceeds the ionising po tential the luminous molecules are or have been charged. If th

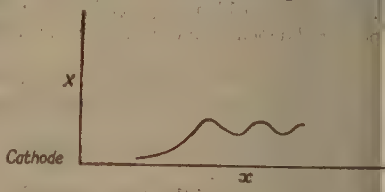

FIG. 15

ations in the energy along the line of discharge are large ugh to make it sink below the radiation potential, then along discharge we shall have: (1) places where the energy is be- the radiation potential,—these will be dark; (2) places where potential is between the radiation potential and the ionising ential,—the molecules here will be luminous and uncharged will, therefore, not move under the electric field; (3) places re the molecules are luminous and charged,—these molecules move down the tube towards the cathode with the velocity ch the positive ion acquires under the electric field. This ocity, when the pressure is low and the field several volts a timetre, as it is in the positive column, may be many thousand timetres per second. Place (1) corresponds to the dark parts he striations, (2) to the stationary luminous parts, while (3) he origin of the striations moving down the tube observed Wulner, Spottiswoode, Aston and Kikuchi.

athode Rays and the Discovery of the Electron.—In 1859 cker observed on the glass of a highly exhausted tube in the ghbourhood of the cathode a bright greenish yellow phosphor- ence, which changed its position when a magnet was ught near to it. About 10 years afterwards Hittorf showed t a solid body placed between a pointed electrode and the walls he tube cast a well-defined shadow of such a shape as to show t the agent producing the phosphorescence travels in straight s at right angles to the surface of the cathode. The name athode rays" for the cause of the phosphorescence was in- duced by Goldstein, who made many important investiga- s on their properties. The opinion held by Goldstein and erally in Germany was that cathode rays were waves in the er. Varley and Crookes advanced the view that they were trified molecules shot off at right angles to the cathode. The covery by Hertz that the cathode rays could pass through thin ers of gold leaf was difficult to reconcile with this view.

he evidence in favour of the cathode rays being electrified par- es was increased by Perrin's discovery that when a pencil of rays entered the opening in a Faraday cylinder they gave it a charge of negative electricity. One difficulty which had n urged against the rays being negatively electrified, viz., t, though they were deflected by a magnetic force, an electric ce produced no effect upon their path—was removed by J. Thomson, who showed that the absence of deflection was to the gas in the tube acting as a screen and protecting the ticles from the electric force. As the gas in the vacuum tube conductor of electricity the rays move inside a conductor of ctricity, and so will not be affected by an external electrified ly. Thomson showed that when the vacuum was very high, that there was but little gas in the tube, the cathode rays re deflected by an electric and magnetic field, and that the ection of the deflection indicated a negative charge on the rticles. His measurement of the deflection by known electric d magnetic forces led to a determination of the mass of the rticles which carried the charge, and showed that these par- les were not atoms or molecules but something with a mass t one-thousandth part of the mass of the lightest atom known, at of hydrogen.

The deflection due to electric and magnetic forces can be cal- lated as follows. Suppose that the particles are travelling rizontally between two parallel horizontal metal plates A, B, intained at a constant difference of potential, there will be vertical electric force F acting between the plates, and if the s of y is vertical the equation of motion of the electrified rticle when it is between the plates is

$$m\frac{d^2y}{dt^2} = Fe$$

y and $\frac{dy}{dt}$ are both zero when the particle enters the region tween the plates, then, when it leaves this region, after a time

$$y = \tfrac{1}{2}\frac{Fe}{m}t^2 \text{ and } \frac{dy}{dt} = \frac{Fe}{m}t$$

ce the electric force is at right angles to the direction of motion the particles, v the velocity of the particles will not alter, and if the deflection is small, $t=l/v$ where l is the length of the plates. Thus

$$y = \tfrac{1}{2}\frac{Fe}{m}\frac{l^2}{v^2} \text{ and } \frac{dy}{dt} = \frac{Fe}{m}\frac{l}{v}$$

Suppose the particles strike a photographic plate or a screen covered with a phosphorescent substance at a distance L from the end of the plates, the y displacement at this place produced by the electric force, is given by the expression

$$y = \tfrac{1}{2}\frac{Fel^2}{mv^2}+\frac{FelL}{mv^2} = \frac{Fel}{mv^2}\left(\frac{l}{2}+L\right)$$

Magnetic Deflection of the Rays.—If the rays go through a uniform magnetic field of length l and strength H, then if the magnetic force is vertical the force acting on the moving particles will be Hev, and will be at right angles to the magnetic force and also to the direction of motion of the rays; *i.e.*, it will be at right angles to the plane of the paper; if z is the displacement of the particle in this direction

$$m\frac{d^2z}{dt^2} = Hev.$$

From this we see that the value of z at the screen is given by

$$z = \frac{Hel}{mv}\left(\frac{l}{2}+L\right)$$

Hence
$$\frac{e}{m} = \frac{z^2}{y}\frac{F}{H^2l\left(\frac{l}{2}+L\right)} \qquad (26)$$

and
$$v = \frac{z}{y}\frac{F}{H} \qquad (27)$$

Thus the measurements of y and z, the electric and magnetic deflections, give the values of e/m and v.

The expressions for y and z have been obtained on the supposition that the electric and magnetic fields acted one at a time and not simultaneously. If, however, y and z are small, their values will not to a first approximation be altered if the electric and magnetic deflections occur simultaneously. Thus by making the cathode rays pass through superposed electric and magnetic fields, e/m and v can be got with one exposure by measuring y and z on the screen or photographic plate.

Since from equation (26) above z^2/y is constant as long as e/m is constant, we see that all the particles of the same kind, whatever their velocity, would strike the screen or plate on a parabola, and that if the rays were a mixture of particles of different kinds each kind of particles would trace out a different parabola. Since z/y only depends upon v, all the particles moving with the same velocity will strike the screen in a straight line.

The determination of e/m for the cathode rays led to results of fundamental and far-reaching importance, for it was found that all the cathode rays had the same value for e/m, and that moreover while for a charged atom of hydrogen in liquid electrolytes e/m was equal to 10^4, when e was measured in electromagnetic units, the value of e/m for the particles in the cathode rays was considerably more than one thousand times this value. Thus if e were the same for the particle as for the hydrogen atom (and we shall see later that this is the case) the mass of the cathode particle is only $\frac{1}{1800}$ of that of an atom of hydrogen, the smallest mass which hitherto had been recognised. Again it was found that whatever metal might be used for the cathode, or whatever might be the gas in the discharge tube, the value of e/m was unaltered. As those particles must have come either from the electrode or the gas, it follows that the particles of the cathode rays are a constituent of the atoms of all the chemical elements. These particles are called "electrons."

After the electrons had once been detected in the cathode rays they were very soon detected under many other conditions and found to be of very widespread occurrence. Thus, for example, it was found that streams of electrons are given out by incandescent metals, the rate of emission increasing very rapidly with the temperature. This has received a very important industrial application in what are known as "hot wire valves," at which a current from a hot cathode passes through a vessel in which the vacuum is so high that the gas takes no part in the discharge; the current, in some cases amounting to several amperes, is carried entirely by electrons. Lenard found that they were emitted by metals exposed to ultra-violet light. They are emitted when Röntgen rays strike against matter and by radio-active substances. The speed of the electrons ejected either by ultra-violet light or by Röntgen rays does not depend upon the intensity of the radiation but only upon the wave length. The energy acquired by the electrons is $=h\nu$, where ν is the frequency of the radiation and h Planck's constant.

Since the cathode rays are deflected by electric and magnetic forces proportionally to the magnitude of these forces, we can use the deflection of the rays as a measure for electric and magnetic forces. As these rays have practically no inertia they are especially adapted to measure very rapidly alternating forces which could not be detected by any index having an appreciable mass. The cathode ray oscillograph, an instrument by which electric and magnetic forces are measured by the deflection of cathode rays, has already been used in many investigations, and is a very important aid to research. Another property of cathode rays is that when they strike against matter they generate Röntgen rays, the hardness of the latter increasing with the speed of the former. The mass of an electron depends upon its velocity; this effect is not appreciable unless the velocity is comparable with that of light but the increase in mass becomes very marked when as in the case of the β rays from radio-active subjects the velocity exceeds 10^{10} cm./seconds. On the theory of Relativity the relation between m_v the mass of an electron moving with the velocity V and m_0 the mass of an electron at rest is

$$m_v = \frac{m_0}{\sqrt{1-v^2/c^2}},$$

where c is the velocity of light. This relation seems to be in agreement with the measurements which have been made on the masses of the β particles.

If the electron is regarded as a small sphere of radius a then it follows from the laws of electromagnetic action that $m_0 = \frac{2}{3}\frac{e^2}{c^2a}$ where e is the charge on an electron in electrostatic measure. The value of e/m_0 found by experiment is $1{\cdot}78\times10^7\times c$, the value of e is $4{\cdot}8\times10^{-10}$, and $c=3\times10^{10}$, hence the value of a from the preceding equation is equal to $1{\cdot}9\times10^{-13}$ cm.

Positive Rays.—Goldstein discovered in 1886 that, if the cathode in a highly exhausted tube was perforated, bundles of a luminous discharge streamed through the aperture into the space behind the cathode. The colour of this discharge depends upon the gas in the tube; thus in hydrogen it is rose colour; in air, yellowish. The colour of the light due to these rays is not the same as that produced when cathode rays pass through the gas. In some gases the difference is very striking; thus in neon the light due to the cathode rays is pale blue, while the discharge which streams through the cathode is a gorgeous red. Goldstein called the rays which stream through the hole in the cathode *Kanalstrahlen;* but as they have been proved to consist of positively charged particles it seems more natural to call them "positive rays." These rays produce phosphorescence when they strike against glass and many other substances, though the phosphorescence is generally of a different colour from that produced by cathode rays. They also affect a photographic plate. It was at first thought that the positive rays were not deflected by a magnet, as magnetic forces which produced large deflections of cathode rays had no appreciable effect upon positive ones. Wien showed, however, by using very strong magnetic fields, that they could be deflected and that the direction of the deflection indicated that they carried a charge of positive electricity; they can also be deflected by electric forces.

By measuring the deflection provided by electric and magnetic fields we can determine by using equations (26) and (27) the value of e/m for the particles which constitute the rays. The result is of great interest. Instead of, as in the cathode rays, e/m having the same
value for all the carriers, we find that e/m has many diffe
values separated by finite intervals; and instead of e/m b
equal to $1{\cdot}78\times10^7$, as in the cathode rays, we find the grea
value of e/m is 10^4, which is the same as its value for a cha
hydrogen atom. The values found for e/m depend on the g
in the discharge tube; the outstanding result is that all t
values of m correspond to masses of atoms or molecules of
chemical elements or compounds. Thus while the determina
of e/m for the cathode rays shows that in a gas at a very
pressure the carriers of the negative electricity are all of the
type, being electrons whose mass is exceedingly small compa
with that of any atom, the determination of e/m for the posi
rays shows that the carriers of the positive electricity are of m
different types; and that all these types correspond to atom
molecules of the chemical elements or compounds. It has alre
been shown that if charged particles, after passing thro
electric and magnetic fields, are received on a screen or ph
graphic plate, all particles, for which e/m is the same, strike

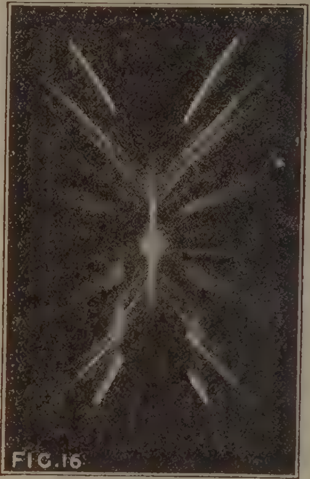

FIG. 16

plate on a parabola, and that for each different value of
there is a separate parabola.

These parabolas are shown in fig. 16, which is a reproduction
a photograph made by allowing the positive rays in a tube c
taining gases liberated by heating a certain mineral to str
against a photographic plate; taken from the top downwa
they correspond respectively to the atom of hydrogen,
molecule of hydrogen, the atom of helium, the atom of carb
with two charges, the atom of nitrogen with two charges,
atom of oxygen with two charges, the atom of carbon with
charge, the atom of nitrogen, the atom of oxygen, the molecule
water, the molecule of CO and that of N_2 (these form one para
ola), the molecule of oxygen, the molecule of CO_2 and the at
of mercury. We find that many of the atoms can carry more th
one charge, for when we find a parabola corresponding to o
value of e/m we frequently find another corresponding to tw
this value; thus carbon, nitrogen and oxygen occur very f
quently with two charges, other atoms such as argon with t
and three charges, while mercury atoms have been detected wi
1, 2, 3, 4, 5, 6, 7 charges. It is significant that the atom of h
drogen never occurs with more than one charge. Multi
charges generally occur on atoms but not on molecules; the
are, however, some molecules such as CO on which double charg
have been found. Some of the positive particles, after passi
through the hole in the cathode, lose their positive charge a
become uncharged, and some of these neutral particles acqui
a negative charge; thus mixed with the positively electrifi
particles there are some negatively electrified ones. This pow
of acquiring a negative charge is confined to certain atoms; th
while the atoms of hydrogen, carbon, oxygen, fluorine occur wi
a negative charge, the atoms of nitrogen, helium, argon and ne
do not. It is exceptional for a molecule to acquire a negati
charge—the molecules of oxygen and carbon, however, can do s

e equation of a parabola formed by a particle on the photo-phic plate has already been given

$$z^2 = \frac{e}{m} yC$$

ere z is measured parallel to the displacement due to the gnetic field and y to that due to the electrostatic. C is a antity which depends on the strength of the electric and gnetic fields and on the position of the photographic plate. If, in fig. 17, we draw a line parallel to the axis of z, the inter-ot made by a parabola on this line will be proportional to $m)^{\frac{1}{2}}$; thus, if the top parabola is due to the atom of hydrogen, next to the molecule of hydrogen, the third to the atom elium and the fourth to that of oxygen, the intercepts AH, AH_2, Ie, AO are in the proportion of 1, $1/\sqrt{2}$, 1/4. Thus by com-ring the intercept made by any parabola X with that made by e parabola due to the hydrogen atom we can find the molecular ight of the substance producing the parabola X.

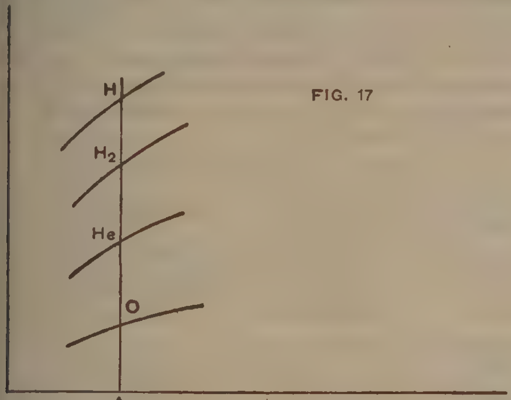

FIG. 17

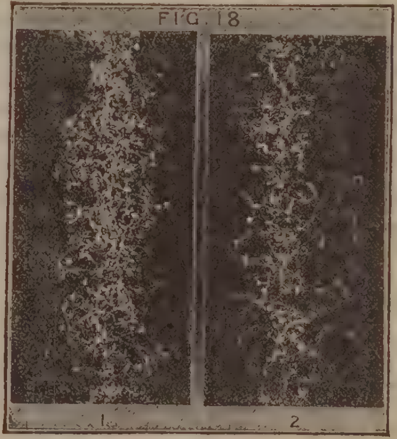
Positive Rays as a Method of Chemical Analysis.—Since from e measurement of the positive ray photographs we can deter-ine the molecular weight of the gases in the discharge tube, we n analyse a gas by putting a small quantity of it in a discharge be and taking a photograph of the positive rays. It is thus a ethod of chemical analysis, and its application has already led the detection of several new substances. In fact, though it s only recently been introduced, more substances have been scovered by this method than have ever been discovered by ectrum analysis. The method has many advantages. In the st place only a very minute quantity of the gas is required; a all fraction of a cubic centimetre of gas at atmospheric pres-re is all that is required to fill the discharge tube at the pressure which the positive rays are produced. Again, the method is ry sensitive, as it will detect the presence of a gas which only rms a small percentage of the gas in the tube. The method not ly detects the presence of the gas, but at the same time termines its molecular weight. It indicates, if the gas is an ement, whether it is monatomic or diatomic; for if it is diatomic will give rise to two parabolas, one due to the atom, the other the molecule. The absence of double or negative charges will ggest that it is a compound and not an elementary gas. The ly ambiguity is that it does not distinguish between two sub-ances of the same molecular weight; thus CO_2, and N_2O give e same parabolas, as also do CO and N_2: we can often, however, move this ambiguity by putting substances in the tube which uld absorb one gas and not the other, and testing whether or t this has removed the parabola.

Use of Positive Rays to Determine Atomic Weight.—The meas-ement of the parabolas give, as we have seen, the atomic ight of the elements producing them; they can therefore be ed to determine the atomic weight of elements which can be roduced in a gaseous state into the discharge tube. This ethod has the great advantage that the presence of impurities es not affect the result. Mr. Aston has lately, by the use of a sitive-ray method for determining atomic weights (*see* ATOMIC WEIGHTS), found the very important fact that, if oxygen is taken as 16, the atomic weights of the elements with the exception of hydrogen are represented by whole numbers. Thus in working with chlorine he found no substance with an atomic weight of 35·4, but two substances with atomic weight of 35 and 37 respectively; he regards these substances as identical in chemical properties and inseparable by chemical reactions, and ordinary chlorine as a mixture of about 3 parts of (35^2) and one part of (37^1). Mr. Aston, by the method of positive-ray analysis, has discovered and measured the masses of the isotopes (*see* ISOTOPES) of most of the chemical elements.

The Charges of Electricity Carried by Gaseous Ions and Electrons.—The deflection of cathode and positive rays by electric and magnetic forces supplies a method for finding the value of e/m; for the determination of e, the charge of an ion, other methods have to be employed. One such method used by J. J. Thomson is based on the important investigation of C. T. R. Wilson on the effect of ions on the deposition of clouds and fogs from supersaturated air. If dust-free air saturated with water vapour is suddenly cooled by expansion, no cloud or fog is deposited unless the supersaturation due to the cooling is very large. C. T. R. Wilson found that if ions are present in the gas they act as nuclei round which drops of water are deposited with a supersaturation much below that required for gas free from ions. A beautiful application of this is the detection of the path of an α particle from a radioactive substance. The α particle produces by collision ions all along its path; if the damp gas through which the particle is passing is suddenly cooled by expansion, drops of water will deposit on the ions and thus mark out the path of the particle. One of Mr. Wilson's photographs of such a path is shown in fig. 18. Mr. Wilson found that less supersaturation is required to deposit water on negative than on positive ions. This result can be applied to find the number of ions in a moist gas, for if the gas is suddenly expanded by an amount sufficient to deposit drops on ions, but not sufficient to produce condensation in their absence, then each ion may be made the centre of a drop, and the problem of counting the ions is reduced to that of counting the drops.

FIG. 18



We can calculate the amount of water that will be deposited by any given expansion of the air: hence since we know the volume of the water we can determine the number of drops if we know the volume of a single drop. Observation of the rate at which a drop falls under gravity will give the size of the drop, for Stokes long ago showed that the velocity of a rain drop falling under gravity is given by the equation $v = \frac{2}{9} g \frac{a^2 \rho}{\mu}$; when v is the velocity of the drop, a its radius, μ the viscosity of the gas, g the acceleration due to gravity, and ρ the density of the gas. It has been found that, with the exceedingly fine drops formed round ions where the radius of the drop is comparable with the free path of the molecules of the gas, the velocity is $\left(1 + \frac{C}{pa}\right)$ times that given by the above equation when C is a constant, and p the pressure. But though this correction makes the relation between a and v a little more complicated, it still enables us to determine a when v is known. Thus the radius, and therefore the volume, of the drop can be determined, and from this, as we have seen, we can deduce the number of ions.

Let n be this number per unit volume; then if a current of electricity is sent through the gas by an electric force X, the current passing through unit area will be neU when U is the mean velocity of the positive and negative ions under the force X. We know that it is proportional to the force and for a force of one volt per cm. is 1·5 cm./second; and hence when X is known U is known, the current neU can be measured, and hence ne deduced; as n has been found by the drops, the value of e can be determined immediately. This was the method used by J. J. Thomson; a simpler method used afterwards by H. A. Wilson was to get drops round the negative ions alone by using an expansion that would deposit moisture on negative but not on positive ions. He then showed the rate of fall of these drops, first under gravity alone, and then under a vertical electrical force X, acting on the drop in the same direction as gravity. Thus, when the electric field is acting, the force on the drop is

$$Xe+\tfrac{4}{3}\pi\rho a^3g,$$

and when it is off the force is only $\frac{4}{3}\pi\rho a^3g$. Thus, if v_1, v are respectively the velocities of the drop when the field is on and off,

$$\frac{Xe+\frac{4}{3}\pi\rho a^3g}{\frac{4}{3}\pi\rho a^3g}=\frac{v_1}{v}$$

or

$$Xe=\tfrac{4}{3}\pi\rho a^3g\frac{(v_1-v)}{v}$$

From v, the rate of fall when the field is off, we can calculate as before the radius of the drop, and from the preceding equation we can determine e. Millikan (*Phil. Mag.*, 34, p.1), who has made most extensive and accurate investigations on the value of e, used a modification of the preceding method. Instead of producing water drops by expansion on the ions, he obtained, by means of a sprayer, minute drops of oil; he observed the motion of one of these under an electric field in a gas which was subject to some ionising agent, and from time to time an ion would strike against the drop and alter the charge; this would alter the velocity, and from the alteration of the velocity he could by a formula similar to that just given calculate the charge communicated to the drop by the ion. The value obtained for e by this method is, in electrostatic units,

$$e=4{\cdot}77\times10^{-10}$$

If M is the mass of an atom of hydrogen the value of E/M can be determined by the positive-ray method, so that as E is known M can be determined. When M is known Avogadro's constant and the number of molecules of hydrogen in a cubic centimetre of gas at standard temperature and pressure are at once determined.

Thus the study of the electrical property of gases gives the most accurate values available of two of the most important constants connected with the constitution of matter. By studying electrified atoms and molecules, we are able to determine their masses and their properties with an accuracy far beyond that attainable by any method which can be used when they are in the normal state. See Sir J. J. Thomson, *Conduction of Electricity Through Gases* (1926) (J. J. T.)

GASOLENE, commonly known in Great Britain as PETROL, is a motor fuel particularly suitable for use in motor vehicles. It has been officially defined by the American Society for Testing Materials as a refined petroleum naphtha which, by its composition, is suitable for use as a carburant in internal-combustion engines. Petroleum naphtha, as understood in the above definition, is any product of petroleum of which not less than 10% distils below 347° F. (175° C.) and not less than 95% below 464° F. (240° C.) when subjected to distillation according to the current tests of the American Society for Testing Materials. The term gasolene (natural gasolene) is applied also to a liq product of natural gas, which, however, in order to be mark able, must be blended with light grades of petroleum gasol On the other hand, among other motor fuels derived from pe leum, which, even in its crude form, is sometimes used for purpose, are kerosene, which is suitable for tractors, and distillate fuel oil employed in the semi-Diesel type of engi Besides serving as fuel in motor-vehicle engines, gasolene is u for aeroplanes, motor-boats, motor rail cars and many kinds stationary engines.

The increase in the use of motor vehicles, particularly in United States, has made the question of gasolene supply a m ter of vital concern. The consumption in the United States d ing 1924 was approximately 7,750,000,000 gal., nearly 500 for each of the 16,000,000 cars then in service. The largest c suming countries outside of the United States are, in ord Great Britain, France, Canada, Argentina, Belgium, Austra and Italy. The European consumption for 1924 is estimated 1,300,000,000 U. S. gal. (⅚ of the imperial gallon). The foll ing tabulation, based on figures supplied by the U.S. Dept. Commerce, shows the production and consumption in the imp tant countries in typical years.

Production and Consumption of Gasolene

Country and Year	Production	Consumption (in U.S. gal.)	
		Gross	Per Capit
United States	U.S. Gal.		
1914	1,460,038,200	1,255,218,538	..
1923	7,555,945,143	6,685,035,280	..
1924	8,959,690,220	7,780,625,085	69·3

1923–4	12,748,800	14,750,000	0·2

Gasolene Supply.—The supply of gasolene depends on th available petroleum reserve (*see* PETROLEUM 21.316), efficienc in refining methods, and economic utilisation. The increase i the yield of gasolene from a given amount of petroleum is to b expected chiefly from more careful fractionation, improve cracking methods, and raising the upper distillation limits in th production of straight run gasolene by straight distillation. Ac cording to an estimate made by the United States Burea of Mines, the gasolene produced from crude oil amounts t ut 33% of the oil entering the refineries. This percentage ht be increased to 55, in the opinion of the Committee of ven on Conservation, American Petroleum Institute. Of ater promise are possible improvements in engine design, as sult of which the energy available from a given amount of olene may be greatly increased (*see* INTERNAL COMBUSTION GINE). It is estimated by C. F. Kettering, president of the eral Motors Research Corporation, that the percentage of rgy in gasolene transformed into work is, on the average, 5, but that this might be increased to 10 through structural hanical changes, thereby almost doubling the transportation iency of a gallon of gasolene.

arketing Methods.—Highly specialised methods for the mar- ing of gasolene have been developed, particularly in the ted States. The gasolene is shipped from refineries in tank s or ships (tankers) to large storage terminals and thence to ller storage tanks along railways. From these it is taken by tor tank truck to "service stations," garages and curb pumps, ere it is pumped into motor vehicles. It is estimated that re are about 100,000 "service stations" in the United States, le innumerable curb pumps are to be found on the city ets and along country highways. Similar marketing methods employed in Canada. In Great Britain and France the dis- ution of petrol was largely effected by tins but the gasolene np has come into wide use. Public service stations for auto- biles are now to be seen also in the principal cities of Germany, gium, northern Italy and other European countries.

nti-knock Fuels.—A significant recent development has been production of a gasolene designed to eliminate or reduce the nock" of an engine. There are also substances on the market ertised to effect the same result if added to ordinary gaso- es. One such compound, known as ethyl gasolene, consists of nmercial gasolene to which has been added a small fraction of of a synthetic oil containing tetraethyl lead. Anti-knock ls are said to increase the mileage per gallon, to reduce carbon osits in the motor, to facilitate starting and to improve en- e efficiency in cold weather. Of greater importance, however, he fact that the elimination of "knock" removes the barrier the introduction of an automobile engine which would greatly rease the mileage per gallon and otherwise compare favoura- with the performance of engines now in use.

asolene Substitutes.—Benzol, derived as a by-product from ing coal, is used to a limited extent as a blend with gasolene the United States, the limitation being due to the relatively all production of benzol. The substitutes for gasolene which mise the greatest usefulness are oil derived from shale and ecially liquid fuel derived from coal. The use of alcohol (*q.v.*) a fuel for internal combustion engines is growing in Great itain, where extraordinary measures have been taken to en- rage research and production of this fuel. The French Govt. o has undertaken research to this end and has encouraged development of a local alcohol industry, the product of ich can be used as fuel. The use of alcohol as a motor fuel Germany was tried some years ago; more recently benzol, pared by the carbonisation of coal and lignite, has been used a motor fuel. Methanol, also, produced on a commercial scale m carbon monoxide and hydrogen by the so-called Bergius thod for the liquefaction of coal, has attained importance a substitute for gasolene. (*See* COAL; FUEL PROBLEMS.)

IBLIOGRAPHY.—*American Petroleum Supply and Demand* (1925); S. Department of Commerce, *World Trade in Gasolene* (1925); A. Boyd, *Gasolene, What Everyone Should Know About It* (1925); K. Mackenzie, *Petroleum Motor Fuel;* A. C. Fieldner and R. L. Brown, *nplete Distillation of Coal and Motor Fuel;* M. C. Whitaker, *ohol Motor Fuels.* (L. M. F.)

GASQUET, FRANCIS AIDAN (1846–), English Roman tholic divine and historian, was born in London Oct. 5 1846. was educated at Downside College, Bath, afterward becoming perior of the Downside Benedictine monastery (1878–84). eated cardinal in 1914, in 1918 he was appointed prefect of Vatican archives. He has produced various works on mediae- church history and liturgies, among them being *Henry VIII. and the English Monasteries* (1888–9); *A Short History of the Catholic Church in England* (1903); *Parish Life in Mediaeval England* (1906); *The Bosworth Psalter* (1908); *Monastic Life in the Middle Ages* (1922); *His Holiness Pope Pius XI.* (1922).

GAUL, GILBERT WILLIAM (1855–1919), American painter (*see* 11.532), died in New York Dec. 21 1919. He was awarded a gold medal at the Appalachian Exposition, Knoxville, in 1910.

GAUVAIN, AUGUSTE (1861–), French journalist and diplomat, was born at Vesoul Oct. 6 1861. From 1889 to 1892 he was on the staff of *Le Journal des Débats* and in 1893 became general secretary to the European Commission of the Danube. In 1904 he was appointed French secretary to the Central Office of International Transport at Berne. In 1908 he returned to the staff of *Le Journal des Débats* and from that time directed its foreign policy. By the continuity and clearness of his views, his freedom from bias and, above all, by his exceptional talent as a writer, M. Gauvain came to exercise considerable influence. He gave early warning of the menace of German imperialism, and more especially of the danger threatened to Europe by the condition and policy of Austria-Hungary. He was an unceasing advocate of energetic action and moderation in aim on the part of the Allies in the World War. Gauvain, who became a member of the Academy of Moral and Political Sciences, published verbatim in 14 volumes all his articles in *Le Journal des Débats* from 1908 to 1920. (*See* FRANCE: HISTORY)

Among his other works are: *Les origines de la guerre européenne* (1915); *L'Europe avant la guerre* (1917); *L'affaire grecque* (1917); *La question Yougoslave* (1918); *L'encerclement de l'Allemagne* (1919).

GDYNIA or GDINGEN.—This Polish seaport and naval base is situated on the small bay of Gdynia, opening out into Danzig Bay, on the Baltic. It is 12 m. northwest of Danzig, with which it is connected by the railway running westerly from that city to Stolp and Stettin. The Polish Govt., in building a railway to the port which will pass over territory entirely Polish, has also a scheme for a canal to the port from a convenient point on the Vistula, thus tapping the whole waterway system of Poland.

During the struggle with Soviet Russia in 1920, the Poles were unable to utilise Danzig for naval or military purposes, and this led them to build a port of their own. A suitable site was found at Gdynia, where a fishing village of about 200 souls already existed. The depth of water near the shore varies from 10 to 20 metres; the bed of the bay gives firm anchorage; and the entrance is sheltered by the peninsula of Hela. The Polish Govt. began the construction of the port in 1921, and by the summer of 1924 had built the southern mole, 550 metres in length, and a breakwater 175 metres long, forming part of the northern mole, together with a landing stage 150 metres long, a narrow gauge railway along the southern mole, an electric power station, water supply and other equipment. A contract for further construction was signed on July 4 1924 by a Franco-Polish syndicate, the date for the completion of the contract being Dec. 31 1930.

Its main provisions are (1) the making of an entrance canal, 11 metres deep, to the harbour, (2) the construction of the harbour with a water area of about 400 ac. and 1,060 metres of quays, together with a basin eight metres deep and a pier for passenger vessels, the depth of water at the quays being from eight to 10 metres and (3) the digging of an inner basin or dock on the foreshore, with a water area of about 100 ac. and a depth of water at the quays of 10 metres. In 1924–5 the northern mole was extended to a length of 700 metres, and considerable dredging and excavation work was done. In addition the Polish Govt. proposes to spend a large sum on the equipment of the port, comprising large warehouses, a grain elevator, powerful cranes, railway sidings and paved roads. In 1930 the port will have quayage for 30 large steamers and a handling capacity annually of 2,500,000 tons, but it will be constructed so as to permit of a great increase in its size and capacity. In 1925, 85 vessels, of 73,351 net tonnage, entered, and 79 vessels, of 69,981 net tonnage, cleared the port, exclusive of coastal shipping.

BIBLIOGRAPHY.—S. Slawski, *Poland's Access to the Sea* (London, 1925); *The Polish Handbook, 1925*, (London, 1925). (R. MAC.)

GEDDES, SIR AUCKLAND CAMPBELL (1879–   ), British politician, was born June 21 1879, the son of Auckland Campbell Geddes of Edinburgh and the younger brother of Sir Eric Geddes, and was educated at George Watson's College, Edinburgh, and Edinburgh University. He studied medicine, qualified as a practitioner, was at the London hospital for a time and later studied at Freiburg. He was a demonstrator and professor of anatomy first at Edinburgh, then at the Royal College of Surgeons, Dublin, and afterwards at McGill University, Montreal. He also had some military experience in the South African War and afterwards in the World War 1914–6.

In 1916 Geddes became director of recruiting, and in Aug. 1917 Minister of National Service. A seat in Parliament was found for him at Basingstoke and he had little difficulty in accommodating himself to parliamentary life. After the Armistice, Sir Auckland, who had been made a K.C.B. in 1917, became President of the Local Govt. Board and Minister of Reconstruction, and in May 1919 President of the Board of Trade. In this latter capacity he began the removal of the barriers to British Trade which the War had necessarily set up, and he had to deal with the difficulties which immediately arose in the coal industry. In this delicate task he was at least temporarily successful, and managed materially to reduce the price of domestic coal. In the same year an opportunity was afforded him to return to academic life by his election as principal of McGill University. He accepted the appointment, subject to its not being operative till the abatement of the coal crisis allowed of his leaving the Board of Trade. But during the delay the Government prevailed on him to accept instead the post of British Ambassador in Washington. His tenure of the Embassy only lasted three and a half years (1920–3), but the time was crowded with important negotiations in which he showed himself a successful diplomatist. On quitting Washington, Sir Auckland, who had been made G.C.M.G. in 1922, left the public service and became chairman of the Rio Tinto Company. He married in 1906 Isabella Gamble, daughter of W. A. Ross of New York.

GEDDES, SIR ERIC CAMPBELL (1875–   ), British man of business and administrator, born in India Sept. 26 1875, was the son of Auckland Campbell Geddes of Edinburgh, and the elder brother of Sir Auckland Geddes. He was educated at the Oxford Military College and Merchiston Castle School, Edinburgh. He gained some business experience at lumbering in the United States, and was afterwards connected with railways—first, the Baltimore and Ohio system, and then the Rohilkhand and Kumaton in India. Returning to England he joined the North Eastern Railway Co. under Sir George Gibb, and, having succeeded him in 1906, was himself the general manager of this line when the World War broke out.

Geddes was one of the business men whom Mr. Lloyd George, on becoming Minister of Munitions, enlisted in Government employ. He became deputy director general of munitions supply, 1915–6, and was then appointed, though a civilian, director general of transportation, and succeeded in bringing the British lines of communication in France into a high state of efficiency. He was knighted in 1916, and in 1917 he was created K.C.B. and G.B.E., being transferred to the Admiralty in May of that year as controller, in order to develop and utilise the whole of the shipbuilding resources of the country and concentrate them under one authority. A month or two later, in spite of having no parliamentary experience, he was appointed First Lord of the Admiralty, and was returned to the House of Commons as M.P. for the borough of Cambridge.

After the Armistice Mr. Lloyd George made use of Sir Eric's powers as an organiser by commissioning him to co-ordinate Government departments in regard to demobilisation. His success in these varied tasks was rewarded in Jan. 1919 by the G.C.B. When the Government was reconstructed in that month, he left the Admiralty in order to organise and preside over a new Ministry of Transport. But in the autumn of 1920 there came the sudden break in trade, and it became evident that the country could not afford a department on the proposed scale. In 1921 a bill introduced by Sir Eric for the re-grouping of the railways was passed; he then resigned office in Oct., and the ministry was
duced in personnel and importance. Sir Eric himself was
pointed in Aug. 1921 chairman of a small committee, la
known as the "Geddes Axe," to recommend public economies
the Government. In various reports in the winter of 1921–2
committee recommended savings amounting to £86,000,000; b
Sir Eric complained that only £52,000,000 of this amount w
actually saved. In 1922 he left Parliament and returned to
business career, becoming chairman of the Dunlop Rubber C
and of Imperial Airways, Ltd. He married in 1900 Gwendol
daughter of the Rev. A. Stokes, and had three sons.

GEDDES, PATRICK (1854–   ), British biologist and socio
gist, was born at Perth Oct. 20 1854. He was educated at Per
Academy, and in London and France, and became demonstrat
in physiology at University College, London, in zoology at Ab
deen and in botany at Edinburgh. In 1883 he was appointed pr
fessor of botany at University College, Dundee (St. Andrew
University) and in 1919 he became professor of sociology a
civics in Bombay University. As a biologist, in collaborati
with James Arthur Thomson, he wrote *The Evolution of S*
(1889; revised ed. 1901); *Evolution* (1911); *Problems of S*
(1912); and *Biology* (1925), tending towards a new Lamarcki
position. Interested in the synthetisation of science with a
and history and its application to the conditions of modern li
especially in the direction of town-planning and housing,
travelled extensively, established a publishing house and pr
moted civic museums and industrial exhibitions. He was o
of the leading members of the Sociological Society founded
1904. His views are embodied in the papers of this society a
in *City Development*, a report to the Carnegie Dunfermli
Trust (1904), and *Cities in Evolution* (1915). He also wro
Chapters in Modern Botany (1893) and *Life and Work of S*
Jagadis C. Bose (1920). In collaboration with Victor Branfo
he edited the series, (*The Making of the Future*, himself contribu
ing volumes, *The Coming Polity* and, with G. Slater, *Ideas at W*

GEIGER, WILHELM (1856–   ), German scholar, was bo
in Nuremberg July 21 1856. He qualified as an academic le
turer in 1886 in Munich and became professor at Erlangen
1891. In 1920 he was appointed professor of Indian and Irania
philology at Munich. He became the publisher of the *Zei*
schrift für Indologie und Iranistik, the *Zeitschrift für Buddhism*
and the *Grundriss der Iranischen Philologie*. His chief works ar
Handbuch der Avestasprache (1879); *Ostiranische Kultur i*
Altertum (1882); *Ceylon, Tagebuchblätter und Reiseerinnerunge*
(1898); *Litteratur und Sprache der Singhalesen* (1900); *Dipavams*
und Mahavamsa und die Entwicklung der geschichtlichen Ueb
lieferung in Ceylon (edited 1905); *Pāli, Litteratur und Spra*
(1916); *Pāli Dhamma* (1921); *Elementarbuch des Sanskrit* (3r
ed., 1923); *Samyutta Nikāya* (Eng. trans., 1924).

GEIKIE, SIR ARCHIBALD (1835–1924), Scottish geologi
(*see* 11.552), received the O.M. in 1914. He died at his residenc
near Haslemere, Surrey, on Nov. 10 1924.

GEIKIE, JAMES (1839–1915), British geologist (*see* 11.55
died in Edinburgh March 1 1915.

GENERATOR: *see* DYNAMO.

GENETICS (*Greek* γένεσις, origin or creation).—This ter
was proposed at the third International conference on hy
bridisation, London, 1906, to denote the study of heredity an
variation. In that sense it has been generally adopted, and b
extension is understood to include the physiology of reproductio
and the art of breeding. Though such inquiries have been pu
sued from the earliest times, the development of a special branc
of science relating to them is recent. The primary incentive wa
the hope that by applying accurate methods of observation an
experiment to the course of heredity and variation a more precis
knowledge of evolutionary processes might be acquired.

Modern theories of evolution are based on the assumption tha
species have arisen by descent with modification, and that th
constancy and diversity which living things manifest in thei
reproduction provide a sufficient basis for that conception. I
is significant that as a result of the preliminary work done unde
the new inspiration, attention has been largely diverted fro

se more philosophical aims. Beliefs current among naturalists,
ecially as to the nature and incidence of variability, were at
e found to be widely incorrect. The scope and character of
se discoveries are referred to below. Their immediate conse-
nce has been that the development of evolutionary theory is
tly suspended or postponed, and activity is concentrated on
exploration of genetical physiology, the theoretical evalua-
of the knowledge thus gained being relegated to the future.

n these researches several methods of investigation are avail-
e. Modern genetics began with an attempt to observe em-
cally the course of contemporary variation from type; but
ugh observations of this class have proved valuable in a pre-
inary survey, and have often been of use as indicating ma-
al for more prolonged investigation, the main advances have
n accomplished by either (1) experimental breeding or (2)
ology. Important sidelights on genetical problems have also
n obtained through the study of developmental mechanics
ntwicklungsmechanik) by experimental methods.

Experimental Breeding

he great stimulus to this method of research was given by the
iscovery in 1900 of Mendel's paper (*see* 18.115). Heredity,
g regarded as a fortuitous and seemingly lawless phenomenon,
s proved to follow regular principles which could in great
asure be ascertained by experiments properly planned. A vast
d was at once thrown open for investigation. Mendel's success
s made possible by his genius for simplification. Working with
s, he made crosses between distinct varieties and watched the
cent of their numerous characteristics, fixing his attention on
h separately, and disregarding other differences. He then
nd that numerous distinctive features behaved in descent as
hey were transmitted as units.

hese determining elements or units are referred to as *factors*
"genes" (a term especially used by American writers, the
ivalent of Johannsen's *Genen*). The differences determined
these factors can commonly be shown to be treated in hered-
as pairs of alternatives or opposites, such as tall and short,
oured and colourless, hairy and smooth, each germ-cell being
ally pure in respect of one or other of the contrasted char-
eristics. This is the principle of *allelomorphism*, and the
mbers of such pairs are called *allelomorphs*. The zygote,
med by two germ-cells united in fertilisation, may be made
of two germ-cells alike in respect of any given pair, in which
se it is said to be *homozygous* in that respect, or it may be a
erozygote if the uniting pair of cells are unlike. Before the
rm-cells of the heterozygote are formed a process of *segrega-*
n occurs, and there is a dissociation between the opposing
ments introduced at fertilisation, such that the resulting germ-
lls are again in normal cases pure in regard to each allelomorph.

In respect of any such pair of differences the character of the
terozygote is sometimes intermediate, but it most often ap-
oaches more nearly to one of the parental types. Not infre-
ently the approach is so close that the pure homozygote cannot
distinguished with certainty from the heterozygote. In
endel's terminology the character thus prevailing is a *dominant*,
e other being *recessive*. The distinction is of importance and is
e basis of certain suggestions as to the possible nature of al-
omorphism.

After the rediscovery of Mendel's work progress was rapid,
d it was soon found that similar principles of descent apply to
great range of characteristics by which living things are dis-
nguished. The number of forms of life studied is now very
rge, and includes most of the kinds of plants and animals which
e readily amenable to experiment or observation. Man is
idently no exception, and we already know that certain
atures of human colouration, especially of hair and eyes, and
veral congenital abnormalities are transmitted according to the
endelian scheme, some being dominant and others recessive.

Scarcely any satisfactory opportunities for studying the
netics of the lower plants (ferns, mosses, algae, etc.) have yet
curred, but one example has been described in a unicellular
ga (Pascher). Of the features by which animals and plants are distinguished most have now been shown to be dependent on segregable elements. Reservation must be made in regard to differences which are simply quantitative, for there is a good deal of evidence suggesting that the elements by which size and weight are determined do not often form themselves into simple allelomorphic pairs. A similar doubt exists in regard to numerical or meristic distinctions.

Abnormalities.—Differences in instinct and other characters dependent on nervous mechanism are not, as such, distinct in their genetical behaviour, and some have been proved to depend on segregable factors or elements. In several breeds of fowls the hens are devoid of maternal instincts, and do not sit on eggs. This characteristic is recessive to the normal instinct, and segregation takes place in regard to it. The same is true of the pacing habit in horses as opposed to the trotting habit. The "waltzing" habit of certain Japanese mice is recessive to the normal, segregates from it and breeds true when it reappears. This example is interesting, since the abnormality is almost certainly a consequence of deformity in the semicircular canals of the ear.

Descent in Man.—As to the descent of the normal mental attributes of man little is known with accuracy, but several abnormalities of the nervous system are known to follow modes of descent which prove them to be subject to segregation. Feeblemindedness is a recessive condition which breeds true. Paralysis agitans is also a recessive. Hereditary chorea descends as a dominant; colour-blindness and a form of night-blindness may also be termed recessive (*see* Sex). In heterozygous combination with the normal there is segregation, but the descent of these conditions is complicated by sex.

It will readily be understood that though the determining factors may be transmitted as units, the distinguishing characters of animals and plants often must be due to the association of many independent units. Of these, some produce their effects separately, but not rarely, though, independently transmitted, two or more unit-factors may be complementary to each other and combine to produce a joint effect or "compound character," as it is sometimes called. Such complementary factors, if separately present in the organism without their complement, need not manifest their presence at all, and it is then only by breeding tests that their existence can be demonstrated.

Organisms may now be represented as aggregates of units which confer upon them their various attributes. The degree to which an organism may be thus resolved is as yet undetermined, but there is presumably a limit to the process, and it is natural to suppose that the detachable elements are implanted on a *basis*, which for a given type is irreducible.

Reversion.—Conceptions, formerly vague, now acquire an exact meaning. For example, reversion or "throwing back" to an ancestral form, previously regarded as a mere caprice of nature, can at once be perceived to be due to one of two definite causes which operate with regularity. The reversion is either (*a*) the reappearance of a recessive characteristic, or (*b*) it is the consequence of the reunion of complementary factors which, though both present together in the ancestor, had been separated by variation and transmitted in distinct strains. For example, when a red-haired child is born to dark-haired parents the fact proves that the two parents are heterozygous in respect of the recessive red, which reappears when two germ-cells carrying it unite in fertilisation. Moreover, if the statistics of a considerable number of such families of children were collected and added together it would be found that the proportion of red-haired was approximately a quarter of the whole. The mere fact that one or both of the parents traces descent from a red-haired ancestor is not the cause of the reversion—for if either of the parents were homozygous in dark hair the red would not have reappeared.

The reversion to an actual or supposed ancestral form consequent on the meeting of complementary factors is less common in the ordinary practice of breeders, but is frequently seen in experimental crossing. When two white orchids crossed together give a coloured flower in F_1, or when a rose-combed fowl bred with a pea-combed bird gives chickens with the walnut comb of the Malay fowl, the production of the unexpected colour or structure is due to complementary action of two independent factors. But the old interpretation of the phenomenon as a consequence of such an ancestor having occurred in the pedigree is illogical and misleading. In the case of the walnut comb, for instance, it is quite possible that either or both of the parent breeds never had a Malay ancestor. The production of a new form by the meeting of complements should be regarded, like the properties of a chemical compound, simply as the empirical consequence of a certain combination of units, without reference to the previous history of those units.

Purity of Type.—Of greater importance, both theoretical and practical, is the fact that it is now possible to assign a precise meaning to this expression. To the pre-Mendelian evolutionist purity was always a matter of degree, which might be gradually and, as it were, asymptotically approached in successive generations of selection, but never actually attained. The practical breeder also has always regarded purity as a property necessarily dependent on a long course of selection. Purity is now seen to be the condition of the animal or plant which is formed by the union of gametes bearing identical units. In respect of any allelomorphic pair purity may thus be conferred, though in respect of other pairs of units the same organism may be impure, *i.e.*, heterozygous, or, in ordinary parlance, cross-bred. This is the central fact of Mendelism, and on it Genetics is based.

The question of purity must therefore be considered separately for each pair of units. A thoroughbred horse, for example, may be pure in a number of characteristics which go to the making of the breed, but it may be impure in, say, colour. A chestnut horse, however, of whatever parentage, is pure-bred in colour, since that colour is the lowest of the series of horse colours, and chestnuts bred together give chestnuts only. By selection, the likelihood of producing purity is increased, but, as will subsequently appear, no amount of selection can ensure purity. On the other hand, purity in respect of any character may be attained at once in any mating by which gametes of similar factorial composition happen to be brought together in fertilisation. From this proposition the corollary follows that the combination of two strains pure in any given respect will give a family uniform as regards the character considered, and the uniformity of such cross-bred families, especially when one of the parents contains few dominant factors, is in practice one of the simplest and most convincing tests of purity.

Genetic Analysis.—By the institution of a series of crosses with varieties and study of the composition of the succeeding generations an *analysis* of the factorial constitution of a given type can be made. The numerical proportions or ratios in which the several combinations of characters are represented, the number of these terms in the series, and their respective genetical powers of transmission furnish the data from which the nature and number of the factors comprising the parental type may be determined. In the earlier article on Mendelism (*see* 18.115) some of the simpler ratios and their significance are explained, but examples of a much higher order of complexity are often encountered. The unravelling of these complications has led to some important discoveries. The many ways in which it may come to pass that two or more terms in a series of factorial combinations may be indistinguishable from each other cannot be enumerated here, but a knowledge of some of the more significant causes of disturbance of what may be called the normal ratios (9:3; 3:1; 9:3:4; 27:9:9:9:3:3:3:1, etc.) is essential to a proper comprehension of Genetics.

Cumulative Factors.—From certain crosses (especially of cereals) into which only one pair of differences had apparently been introduced it was observed (Nilsson-Ehle; East) that the recessives reappearing in F_2 were only 1:1:5 instead of the usual 1:3. Investigation proved that from the dominant side *two* factors with identical functions, though belonging to distinct pairs, had been introduced. Consequently, among the dominants in F_2 were some containing both these factors and others having one only. Various results suggest that this multiplication, or better, *accumulation*, of similar factors is a common occurrence, and that the process may be extended in special cases.

Inhibiting and Lethal Factors.—Many factors act by produc
a negative result, inhibiting the development of some charac
the determining elements of which are present though their act
is not perceptible or largely diminished. Of these the most ea
demonstrable operate by inhibiting the formation of colour.
white pigment of the coats of animals and the feathers of birds
of flowers, for example, is commonly due to the absence of
elements necessary for the formation of colour, but both
animals and in plants varieties have been found which are wh
or nearly so, not through absence of pigment, but through
presence of factors which, in some way not yet defined, inhi
the production of the coloured pigments. From some mating
mixture of white individuals may be obtained, which to the
look alike or nearly so, though they represent various facto
terms and are genetically dissimilar. The process of inhibit
may be carried much further, and there are well-establish
instances in which the animal or the plant cannot live if it
homozygous (containing two "doses," in popular terms) fo
given factor.

The classical instance of such *lethal* factors, as Morgan
called them, was met with in the breeding of yellow mice (Cuén
F. M. Durham). Mice with yellow coats, bred together, giv
majority of yellow, but always throw a proportion of some ot
colour—for example, chocolate or black. Since in mice yell
is a dominant, it is clearly caused by a factor which the game
can carry. But the union of two gametes, both carrying t
factor, does not give rise to a viable animal. It was suggest
that two such gametes could not unite in fertilisation, but la
work has practically proved that these fertilisations occur a
that the resulting embryo perishes at an early stage (Ibse
The physiological action of the yellow factor in causing death
not known. In plants the "golden"-leaved varieties are co
parable. They cannot breed true, but throw 2 yellow: 1 gre
The purely yellow term is missing, and is clearly not viable (Ba
The suggestion has been made that the yellow factor acts
merely negatively by diluting the amount of chlorophyll, but
inhibiting its formation, probably producing a body with t
specific power. This is the more likely since golden varieties
dull weather turn almost a full green, whereas in sunlight th
bleach to a full yellow, a fact indicating that the production
the inhibiting body is promoted by sunlight. Two doses of t
factor kill the plant altogether, probably during embryonic li

Linkage.—At an early stage in these inquiries it was observ
that factorial units belonging to separate allelomorphic pairs
not always distributed independently among the gametes o
heterozygote, but that some combinations occur regularly wit
greater frequency than others. The next step was the discove
that this *linkage* depends on the association of the linked fact
in the parent from which the heterozygote was formed. F
example, if a form *AB* is crossed with *ab* the normal expectati
is that the double heterozygote *AaBb* will form gametes *A*
Ab, *aB*, *ab* in equal numbers; but if there is linkage between
and *B*, then the parental combinations *AB* and *ab* will be mo
frequently represented in the gametic series than the other,
"cross-over" combinations, *Ab* and *aB*. But if the original cro
were in the form *Ab* x *aB*, then the most frequent gametes w
be *Ab* and *aB*, the cross-overs, *AB* and *ab* being the rarer. Th
observation forms the starting-point from which modern genetic
theory has been very largely developed.

The terminology followed above is that introduced by T.
Morgan, to whom progress has been especially due. It is som
times convenient to distinguish the case in which the two dom
nants (*AB* x *ab*) are introduced together by the parent as *cou*
ling, and the converse (*Ab* x *aB*) as *repulsion*, but the physi
logical process is now recognised as being clearly the same in bot
cases, and there is no difference in the numerical proportions
which the parental combinations respectively reappear.
should be observed that the factors thus linked have plainly
connection with each other as regards the effects which they pr
duce in the zygote, but may concern the most dissimilar chara
ters. For instance, in the example first observed the linkage w
that between the factor which makes the flower of the sweet p

e or purple (as distinguished from red) and that which makes
, pollen grains long (as distinguished from round). According
the proportion of cross-overs is small or large the linkage is
re or less complete. If both parental and cross-over terms are
ially common there is no linkage. The most satisfactory test
he linkage-ratio is obviously provided by breeding the double
erozygote (*Aa–Bb*) with the double recessive (*aabb*), and this
ting should be carried out reciprocally since it is known that
plants (*e.g.*, *Primula sinensis*) male and female sides of the
ne plant may show different degrees of linkage (R. P. Gregory),
l that in animals (*e.g.*, *Drosophila* and the silkworm) crossing-
er may be absent in one sex though occurring in the other.

Allelomorphism: Multiple Allelomorphs.—Apart from linkage,
regation is always a separation of units affecting the same
racter, and from a very large range of observations it is possi-
to represent the distinction between the allelomorphic pair
one in which a *positive* element separates from a *negative*. In
ier words, allelomorphism may commonly be conceived as a
ference which consists in the *presence* of something on the one
e and its *absence* on the other. This conception is applicable
enever there is definitely pronounced dominance. It is
tural that the characteristic which possesses dominance should
looked upon as due to the positive or present element, the
essive being the consequence of its absence. Nevertheless,
ere is as yet no strict proof that this representation is physio-
gically correct. For since we know that many factors may
erate by inhibition it is always possible to *invert* the con-
ntional representation and by putting negative for positive, to
ike a factorial scheme which equally agrees with the observed
sults. Conventionally, for instance, the tall pea is represented
either *TT* (homozygous) or *Tt* (heterozygous), the dwarf
ing *tt*, from which the positive element *T* tallness is absent.
But we cannot positively declare that the dwarfs may not be
homozygous in the presence of an inhibitor *I*, whereas the tall
ints might be either *Ii* heterozygous, or *ii* homozygous in re-
ect of the absence of this inhibitor. The significance of this
ernative mode of representation will be apparent when the
plication of factorial systems to evolutionary theory is at-
mpted (*see* MENDELISM). But when the heterozygote is inter-
ediate between the two homozygous forms the "presence-and-
sence" method of representation cannot be applied with any
nfidence. From the existence of such cases and from certain
her considerations it has been urged, especially by American
neticists, that the method of representation by presence-and-
sence is incorrect, and that a negative allelomorph should be
eated as a real entity. There is no valid means of deciding this
estion as yet. The probability is perhaps that the absence
ould always be regarded as relative only. As a mode of sym-
lic expression the representation of the two allelomorphs as
ffering quantitatively is often convenient, though perhaps not
iversally applicable.

Types of Allelomorphs.—Allelomorphism is, as the term
plies, a relation between two alternatives, and in any one
gote there can be no more than two. Nevertheless, there are
stances in which the same unit-factor enters into heterozygous
mbination with various alternatives in different zygotes, and
ch of these may thus be in allelomorphic relation with it.
ternatives composing such a group of possibilities have been
rmed by Morgan *multiple allelomorphs*, and this expression is
mmonly adopted. Its use, however, makes the application of
e term "multiple" to "factors" in a totally different sense
probable source of confusion, and for this reason the word
mulative or some equivalent is there to be preferred as suggested
ove. The distinctions which together make up a set of multiple
elomorphs may commonly be recognised as a series of *quanti-
ive* differences, the character affected being throughout the
ies the same.

Albinism in Rabbits.—One of the most familiar illustrations
provided by the degree of albinism in rabbits. The fully albino
rm is white with pink eyes, but there is a variety called Hima-
yan, which, though born white with pink eyes, acquires some
gment in certain parts. Himalayan is dominant to albino but recessive to the ordinary coloured types. If a coloured type is bred with Himalayan the heterozygotes so raised cannot, when interbred, throw albinos, nor can heterozygotes raised from coloured x albinos throw Himalayans, even though the albino used as their parent had itself been extracted from Himalayans. The degree of albinism put in by the parents comes out in F_2 and in the same degree. Hence it is not possible from similar parents to breed all three kinds, but on the other hand, each family can contain at most two of them.

This phenomenon can be interpreted in either of two ways. The Himalayan pattern may be regarded simply as a quantitative diminution or fraction of the sum total of colour needed to make the self-coloured type. The real albino is thus produced by the absence of the whole unit needed for colour, and the Himalayan by the absence of part of this total. It is then obvious that the heterozygote, coloured x albino, could never produce a Himalayan unless the colour-complex broke up again *de novo*. But on the analogy of the behaviour of other colour patterns the self and the Himalayan might be conceived as each consisting of two units: one for colour and one a factor determining its pattern, intensity or distribution. If there were a very close linkage between each "pattern," factor and colour the observed facts could then be represented; but by continued breeding the supporters of this view would expect the missing cross-over to appear eventually as either a Himalayan associated with recessive albinos or an albino associated with recessive Himalayan. On the ground of simplicity the former view seems preferable. The significance of these two alternatives will presently appear.

Study of Grasshoppers.—More complex illustrations of these possibilities have been described by Nabours in certain grasshoppers (*Paratettix*). The species studied presents a long series of colour forms, and experimental breeding showed that with certain exceptions all the pure forms behaved as if allelomorphic to each other. In other words, whichever two pure forms *A* and *B* were crossed together, the F_1 generation was *A B*, giving in F_2 a family approximating to $1AA{:}2AB{:}1BB$. The whole series of colours is thus often described as a vast set of multiple allelomorphs. Nevertheless, there are curious features in this case which raise a doubt whether this account is really correct. Many of the distinctions are plainly *quantitative* degrees in development of some one type of coloration whch are, as might be expected, allelomorphic to each other (*cf.* the Himalayan rabbit): but among the elements comprising the total colouration of these grasshoppers there are several in which both the pigments and the positions they occupy are so distinct that the characters cannot easily be represented as determined by factors allelomorphic to each other. Only by a very loose application of the term 'colour' can the distinctions be said to apply to the same character. Hence, in this hitherto generally accepted illustration it seems probable that, in so far as the distinctions are actually quantitative differences in one respect, true allelomorphism may be recognised, but that the appearance of an allelomorphism between factors of differing scope is more probably spurious and referable to close linkage (*cf.* Haldane). No decision on this question can yet be made with any confidence.

Allelomorphic Complexes.—Among modern extensions of genetical theory none is more remarkable than the discovery that large and apparently miscellaneous groups of characters are sometimes governed by elements capable of segregating collectively as a single complex. Nevertheless, in the case of sex, we have long been familiar with one example. Since the distinction between the two sexes in many animals is known to behave in segregation as if it depended on a single Mendelian factor, we have to recognise that a number of distinctions of all kinds, structural and functional, may be treated in segregation as factorially single. In the special case of sex we know further that particular genetic elements may be detached from the complex (*e.g.*, the elements governing spur and broodiness in fowls, the beard in man, etc.), though the possible limits of such disintegration are unknown.

Oenotheras.—Renner's experiments have shown that the inheritance of the protean variations of several Oenotheras is largely effected by the transmission of similar complexes. Each of these large composite factors or groups of factors (in so far as they prove to be divisible) may govern many characters of form, colour, habit, etc., and the whole group is transmitted as a single heritable entity. Similar discoveries will probably be made in regard to other forms. The details are beyond the scope of this article, but it may be remarked that these complexes in Oenothera supply one of the most striking illustrations of the phenomenon which may be called *anisogeny* (see " Somatic Segregation," *inf.*) or the relegation of a factor or factors exclusively to one sex-side of a plant. For instance, whereas *Oenothera Lamarckiana*, the species which provided de Vries with his most celebrated but unsound evidence of mutation, can be proved to be a permanently heterozygous form having two complexes equally distributed in segregation to both the male and the female gametes, the species *biennis* and many more, though similarly heterozygotes of two complexes, in segregation pass the whole of the one complex into the male gametes and the whole of the other into the female gametes.

The question whether the apparently simple factors which commonly behave as Mendelian units are capable of further resolution is of much theoretical importance in its bearing on the problem of the nature of variation. Such a complex factor as that which determines sex may evidently break up into simpler components, but for various reasons some geneticists incline to the belief that factors in general are permanent and irresoluble. Whenever a series in F_2 derived from two clearly distinct and true-breeding types, consists of a number of intergrading forms, it is possible to interpret this result as due to the operation of a multitude of *originally* distinct factors, or to the fractionation of some one or more of them. Not very rarely in such series an extreme parental type fails to reappear at all [*e.g.*, the many-feathered tail of the fan-tail pigeon (Morgan), or the long glumes of Polish wheat from crosses with ordinary types. It is difficult to interpret the absence of the extremes simply as an indication of their statistical infrequency. The production of an innumerable series of colour-forms, as in the sweet pea, is almost certainly due to the fractionation of the colour-complex. Until systematic crossing was undertaken, the extremes existed, but the intergrades did not. So also in *Drosophila*, of which the normal eye is red, a profusion of intergrades ranging to the white eye, which was discovered first, has now appeared. Though " mutation " is involved, the essential change is probably the disintegration or fractionation of the originally integral complex.

CYTOLOGICAL INTERPRETATIONS OF GENETIC PHENOMENA

Soon after the rediscovery of Mendelian analysis the plausible suggestion was made that the behaviour of the chromosomes in the course of the maturation divisions was consistent with what might be expected if they were actually the bearers of segregable factors. Since, however, the number of segregating factors in many forms far exceeds the number of chromosomes possessed by those forms, it is clear that if the chromosomes are the carriers of factors they must be capable of carrying many. The discovery of linkage, and especially of the fact that linkage was determined by the parental associations of the factors, pointed in the same direction, for, as hinted (by Punnett) in the earlier article on Mendelism (*see* 18.115), linkage or " gametic coupling " as it was then called might not unreasonably be supposed to be based on chromosomal association. The first development of this conception was made by T. H. Morgan, whose investigations relating mainly to the fruit-fly *Drosophila*, have inaugurated a new phase in the development of genetical theory. This insect is a subject unusally favourable for experiment inasmuch as it offers a profusion of variations or " mutations," and reproduces itself with great rapidity under laboratory conditions.

The work began with the observation that the eyes, normally red, may be white, and that this variation is sex-linked, behaving genetically precisely as colour-blindness does in man. The white-eyed male mated with normal females produces offspring all normal. Of these the sons cannot transmit the abnormality at all, whereas the daughters mated with normal males transmit the white eye to half their sons. White-eyed females can only produced as daughters of white-eyed fathers and all the sons such females are white-eyed. Supposing the male to possess X-chromosome, this system of descent would be represente it were assumed that in the normal the X-chromosome carri the dominant factor for red eye (*see* SEX). The linkage with s is thus found to be an expression of the association of the t determining factors for sex and red eye in the same ch mosome.

Numerous other sex-linked characters were soon after d covered, to which the same considerations apply, all collective composing one linkage-group. The other factors identified *Drosophila*, amounting to more than a hundred, can all represented as grouped in three separate linkage-systems whi with the sex-linked group, make four; and since from cytologi observations the haploid number of chromosomes in this ani is also 4 the inference is drawn that the factors composing ea linkage-group are borne in one chromosome. Developing t conception, Morgan suggests that the factors are arranged in t chromosomes as beads on a string, each having a position norma ly fixed in relation to the rest. Crossing-over is thus represent as the consequence of an exchange of material between hom ogous pairs of chromosomes in synapsis. (*See* CYTOLOGY.)

The pairs of chromosomes which then conjugate are with mu probability regarded as respectively of maternal and patern origin. The conjugating pairs seem to twist round each othe and occasionally there is (especially in Amphibia) an appearan of anastomosis between them which is regarded as providing an exchange of material between the homologous pairs, and th for the formation of cross-overs. According as the linkage b tween two factors is more or less complete it is supposed that t distance between the position of the two factors in the chr mosome is smaller or greater, and in proportion as factors a placed close together the probability of their being separated the process of twisting and anastomosis is regarded as diminishe

The proportion of cross-overs is thus taken as a measure of t position of two factors in the chromosome. If A, B and C a three factors in the linkage group, and the closeness of the linkag between A and B and between B and C respectively be det mined experimentally, then from these two the linkage betwe A and C can be calculated, and the result of the calculation commonly found to agree with the value found experimenta for that linkage. In this way the relative " loci " of numero factors have been determined with fair consistency, and the fa that this can be done forms a strong argument for the belief th in some way at least the factors must be disposed in linear sy tems. That these systems are actually arranged along the lin of the chromosomes is as yet a matter of inference.

Attention must be called to the curious fact that in *Drosophi* crossing-over never occurs in the males in any of the four linkag systems. As in most examples of sex-linkage studies, the linka with the sex-factor is always complete; but all the other fact are liable to crossing-over in the female, though among the ma gametes the original parental combinations reappear unchange Conversely Tanaka, examining linkages in the silkworm, o served that a pair of linked factors show crossing-over in the mal but not in the female, and the two facts together suggest som limitation of crossing-over to the sex which is homozygous in s the female in Diptera, the male in Lepidoptera. The develo ment of the idea here outlined has become the subject of ve active research and is described in a copious but somewh esoteric literature, which can be followed only with difficulty b those not personally engaged in the work. That the outcome o these researches has led to a valuable codification of geneti principles is not in dispute; but until the main thesis, that th number of independent factors or of linkage-systems is neve greater than the haploid number of chromosomes, has bee shown to hold generally for animals and plants, this account o the nature of linkage, though probable, cannot be regarded a proved. The defect of the theory at the present time is that i rests on many subordinate hypotheses which are not all capabl of independent verification.

he position of the factors, for example, is believed to be liable changes due to the action of other factors, the effects of age l miscellaneous influences difficult to distinguish. Errors of -division long regarded as the most probable source of varia- n, may also cause disturbance. In two very remarkable in- nces it has been found possible to connect a disturbance in the mal course of heredity with a visible cytological irregularity— ied by Bridges "non-disjunction." In a certain family he ob- ved that a sex-linked character failed to follow its normal dis- ution to the sexes, and he was able to find that in this family sex-chromosomes showed corresponding irregularities. In he obtained similar evidence in regard to the fourth chromo- ne and the group of genes attributed to it. Thus a definite ociation between particular chromosomes and the transferable tors must certainly exist.

iant Forms.—The interrelation of genetical and cytological enomena is further illustrated by the behaviour of "Giant ms." This name is applied to certain varieties (chiefly of nts) in which the haploid and diploid numbers of chromo- nes are double those of normal forms. R. P. Gregory bred h varieties of *Primula sinensis* and found that in respect of ious allelomorphs they might be quadripartite and not merely artite as the normals are. A plant, for example, might be *RR* in colour or leaf-shape, and in consequence of the extra essive elements, not distinguishable from the ordinary re- sive, though in fact capable of throwing a small proportion of minants. Since recent cytological studies have shown that ies of allied forms may contain various multiples of the lowest ploid number (Chrysanthemum, for instance, having 9, 18, 27, or 45) various extensions on these lines may be expected.

omatic Segregation.—In the genetics of plants a number of enomena have been encountered which are difficult to reconcile h the view, otherwise not unacceptable, that the distribution the factors occurs exclusively in the maturation processes of germ-cells. Apart from certain special conditions best known variegated plants (which are sometimes irregular mosaics and netimes consist of an outer "skin" and an inner "core," similar in their genetical potentialities) there are many plants which the distribution of factors must have been laid down ore the formation of germ-cells. E. R. Saunders's results proved t in certain stocks (*Matthiola*) the pollen all carried double- s though the ovules were mixed in character, single and double. Pellew showed that in the hermaphrodite *Campanula car- ica* "pelviformis" the pollen bore exclusively femaleness and ponderantly white flower-colour (the plant being hetero- gous for blue). The pollen of *Begonia Davisii* (a wild species th single flowers) carries doubleness exclusively, and several nilar examples are known, in all of which the segregation of aracters must precede the maturation of the germ-cells. Thus, ile it is not a question that segregation depends on some cell- ision, and very possibly on a differentiation of the chromo- nes, there is evidence that the cell-division in which this dif- entiation occurs must at least sometimes precede germ-forma- n. As mentioned, in *Oenothera* this "anisogenous" distribu- n is exceptionally frequent.

Bearing on Evolutionary Theory.—This aspect of genetics can ly be briefly treated here (*see* also MENDELISM). Genetic alysis has shown that the appearance of variability as a con- nporary and widespread phenomenon is largely illusory. On dying a variable species critically it is found that the various ms cannot all produce each other as was formerly assumed, t that they stand in a regular descending order, being terms in series of combinations of definite factors. Such series are no idence of contemporary variability. Many of the terms can separated in the homozygous condition, and thereafter may ed perfectly true. Even such an appearance of variability as at seen in polymorphic species is frequently not above sus- ion of being the consequences of a cross, more or less remote. ntemporary variation certainly may occur; but of the con- nporary origination of new species, or of the occurrence of etic changes which can be colourably interpreted as likely to d to the production of incipient species in a strict sense, no indication has been found. That the forms of life have been evolved from dissimilar precedent forms we know from the geological record, but as to the process by which this evolution has come to pass we are still in ignorance. All that can be said at present is that variation most commonly arises as an error of cell-division, and that it is quite conceivable that new species have so arisen.

GENEVA, Switzerland (*see* 11.587), had in 1920 a population of 135,059, including suburban districts. In the city proper it was 56,292. Geneva has been much changed in recent years, a large number of public and private buildings having been erected. The manufacture of motor-cars is a new industry, but it is as much an educational and intellectual centre as in the past. An historical and art museum was opened in the Boulevard Helvetique in 1919, and various collections of arms, pottery, coins, pictures, etc., including those from the Arsenal and the Musée Rath, have been brought together there. The Musée Rath, which was the International Prisoners of War Bureau during the World War, is now used for exhibitions. The imposing Electoral Palace was rebuilt with a large hall in 1913–6. A bridge to carry a loop line between the two railway stations has been thrown across the Rhone below the junction with the Arve. A Reformation monument, begun in 1909 on the 400th anniversary of Calvin's birth, was unveiled in 1917; it represents a stretch of rampart, the wall of Geneva with a narrow moat in front. In the centre are colossal figures of Calvin and others, with statues on each side of eminent champions of the Reformation, and bas-reliefs and monumental inscriptions between.

Geneva was chosen in 1919 as the seat of the League of Nations. The Assembly met first in 1920 in the Hall of the Reformation, built by public subscription in memory of Calvin, near the Grand Quay. The league secretariat is housed in the Palace of the Nations, formerly a hotel, beyond the Jetée des Pâques. In Dec. 1925 this building was put up for sale, but as there were no buyers it was decided to retain it for the use of the league. A tablet in memory of President Wilson was placed on the terrace wall in 1924. The International Labour Organisation was housed at first near the Ariana Museum, but for it a new building has been erected near Parc Mon Répos. The office of the International Red Cross is in the Rue de la Promenade du Pin, in the southeast part of Geneva.

GENOA (*see* 11.597), the chief port of Italy and capital of the province of Genoa, had a population of 316,217 in the municipal area of about 12 sq. m. in 1921. The industrial quarter of San Pier d'Arena on the west is now joined to Genoa, and there is a growing residential quarter beyond the Torente Bisagno to the southeast, to which the Via Venti Settembre gives direct access. Large buildings include the imposing Banca d'Italia in the Via Dante, and a building containing the bourse, the post office and a theatre in Piazza de Ferrari. The improvement of this piazza, the central square, was begun in 1913; blocks of houses have been demolished, and the area opened up. The historic Palazzo San Giorgio has undergone complete restoration, and is now the headquarters of the harbour board. A fine new sea front, the Corso d'Italia, adds considerably to the attractiveness of the new residential quarter. During the present century suburbs have arisen on the higher ground, and the Via di Circomvallazione a Monte has been laid out over the hills behind the city.

The tonnage of the port is growing, and is considerably higher than that of any other in Italy, representing almost one-fifth of the total tonnage of the country. Exports are on an average hardly an eighth of the imports, which are chiefly coal and cereals, and the marked drop which began in 1917 was due mainly to the decrease in coal. The doubling of the railway track to Pisa and the development of the stations at San Pier d'Arena and at Genoa Brignole, about two m. east of the principal station, with the extension of electric power to the main line towards Turin and along the coastal line, have improved the port's facilities. A scheme for the extension of the harbour, taken in hand in 1922, included the new Vittorio Emanuele and San Pier d'Arena basins. Shipbuilding is increasing in importance, and there is a considerable motor car industry; the manufacture of hats is also a growing trade.

GENOA, CONFERENCE OF, (April 10–May 19 1922,) a meeting of representatives of the British self-governing Dominions and of 29 European states, including not only the Allies and ex-neutrals, but all the ex-enemy Powers except Turkey (who was excluded on the ground that she was an Asiatic country). Above all, the conference was attended by representatives of Soviet Russia, and the dominant issue was the renewal of relations between Russia and the countries of Europe. The principal result achieved, however, was one which the organisers of the conference had not intended, namely, the signature at Rapallo, on April 16 1922, of a separate treaty between Soviet Russia and Germany.

The prospects of the Genoa conference had been somewhat clouded, before it assembled, by the wave of anti-Liberal feeling in France, which declared itself politically in the superseding of M. Briand by M. Poincaré as Prime Minister. Since the project of the Genoa conference had already been accepted by the Supreme Council, including the representative of France, before M. Poincaré came into power, he could not reject it altogether, but he took every possible step to interpret the agreed programme in the narrowest sense, and to hedge the participation of Russia with the fullest possible restrictions. He refrained from attending the conference but enforced his policy by giving detailed and stringent instructions to his representative, M. Barthou.

The general conference was preceded by a meeting between M. Poincaré and Mr. Lloyd George at Boulogne on Feb. 25, a meeting of Allied economic experts in London from March 20 to 28 which drew up detailed agenda for Genoa, and two other preliminary meetings of a regional character, one between the members of the Little Entente at Belgrade, and another at Warsaw between Poland, Latvia, Estonia and Finland. The parties represented at Warsaw subsequently conferred at Riga with representatives of Soviet Russia. The invitation to Genoa was accepted by the Soviet Govt. with alacrity, but was declined by the United States.

Adverse Influence of the Rapallo Treaty.—At its first plenary session the conference set up four commissions, the first to examine methods of putting into practice the principles of the Cannes' resolution of Jan. 6 1922 (*see* CANNES, CONFERENCE OF), while the other three were to deal respectively with financial subjects, economic and commercial subjects and transport. These th latter commissions, which were concerned with technical qu tions, all reported before the conference came to an end; but th reports were bound to remain academic unless the first co mission achieved positive results. The task of the first comn sion was more difficult, because it was general and politica character, and its work was soon suspended in favour of infor discussions between the three principal Allied Powers a Belgium on the one side, and the Russians on the other. T Germans, who felt themselves left out in the cold, retorted negotiating their separate treaty with the Russians at Rapa in which, at least on paper, the objects of the Genoa confere were achieved as between these two parties by a mutual nunciation of reparation claims and a resumption of normal c sular and diplomatic relations.

However, this separate Russo-German treaty damaged t general prospects of the conference by the shock which it ga to the Allies, and especially to Belgium and France, who, e since the Armistice, had been oppressed by the nightmare o military alliance between Germany and Russia. The Rapa treaty seemed like a first step in this direction, even though t published text contained no military clauses, and the All addressed a series of acrimonious though ineffective notes on t subject to the German delegation. In these circumstances the was little prospect of success for a general pact of non-aggressi which Mr. Lloyd George suggested on April 25. Meanwhile the very first session, M. Barthou had had a hostile encount with the principal Russian delegate, M. Chicherin; but the co ference actually broke down through the intransigence of B gium. When an attempt was made to secure a common draft proposals to be presented by the European delegates to t Russians, the Belgians insisted upon the integral restitution foreign-owned private property in Russia. M. Barthou su ported the Belgian contention, and was himself supported in th attitude by M. Poincaré. Eventually a formula on the Briti lines was carried over M. Barthou's head, even Belgium final giving way, but it was so evident that, with Great Britain a France divided, no positive result could be achieved, that t Genoa conference was quietly wound up by remitting its agen to a mixed commission of experts. This conference of exper duly met at the Hague from June 26 to July 20 1922, but foundered, like the Genoa conference, on the rock of foreig owned private property in Russia, in regard to which the Russia and the Franco-Belgian views again proved incompatible.

The Reconstruction Standpoint.—Although the Genoa confe ence led to no positive results, it was interesting as the first ge eral European conference after the War of 1914–8, and becau economic and financial problems were approached from the poi of view of reconstruction, and not of reparation. It was als interesting as the first attempt at a settlement between th European governments and Soviet Russia. At Genoa the diff culties which proved crucial on later occasions were alread encountered. (A. J. T.)

GENTILE, GIOVANNI (1875–), Italian philosopher an politician, was born at Castelvetrano (Trapani) May 29 187 He studied literature and philosophy at the University of Pa lermo, and after a series of university appointments became i 1918 professor of the history of philosophy in the University o Rome where he founded and became director of the school o philosophy. Two years later he founded the *Giornale critico dell filosofia italiana.* Created a Senator in 1918, he supported th Fascist movement from its beginnings, and when Mussolini Govt. came into power, Gentile was appointed Minister of Edu cation. He was then a Liberal, but subsequently joined th Fascist party, of which he became a prominent member. As Min ister of Education he carried out an organic reform of the Italia educational system, abolished the traditional shibboleths positivist and materialist teaching, and suppressed many inve erate abuses. He introduced the system of state examination and also the teaching of religion into the elementary schools The universities wholly maintained by the State were limited t 10, while others, maintained privately or by local administra ns. received state subsidies if they complied with certain ndards. Among Gentile's numerous works are: *Il modernismo rapporti tra religione e filosofia* (1909), *I problemi della scol- ca e il pensiero italiano* (1913), *I fondamenti della filosofia diritto* (1917), *Le origini della filosofia contemporanea in Italia* vol., 1917–23), *Il Problema scolastico del dopo guerra* (1920), *Riforma dell' educazione* (1920), *Il Fascismo al governo della ola* (1924), *Che cosa e il fascismo* (1925), etc.

EODESY (*see* 11.607 and 8.801).—The geoid is the surface which ncides with the ocean surfaces and their hypothetical continu- ons inland in imaginary channels; all tidal movement being sidered suppressed. The study of the form of the geoid, fre- ently referred to as the "Figure of the Earth," is a main ob- t of geodesy. It has been prosecuted by various agencies in arated portions of the land areas. Even in 1926 only a small ction of the total area of the globe has been examined.

uch results as have been obtained may be co-ordinated by assumption that the geoid does not differ greatly from a eroid (ellipsoid of revolution); and the assumption of an ellip- d of three unequal axes is not at present considered useful. etermination of the Figure of the Earth" may be used con- iently in the restricted sense of determination of the elements the most suitable spheroid; while the science of geodesy em- ces further the study of the actual geoidal form in detail, l even the explanation of this form.

igures of the Earth.—During the progress of the science and growth of observation results, various figures of the earth ve been obtained. Each Survey department has made use of t figure which at the time seemed best. A variety of spheroids now in use as reference figures, on which the calculations of corresponding surveys are based. There is growing inconven- ce in this, and it would be ideal if all the separate geodetic veys could express their results in terms of a single spheroid. hough there are technical difficulties in the relation of the gins of separate surveys to any unique spheroid, it was none less decided at the meeting of the International Union of odesy and Geophysics at Madrid in 1924 that one spheroid uld be internationalised and that, so far as practicable, results uld be expressed in terms of it. The International Spheroid hat determined by J. F. Hayford in 1909.[1]

quatorial radius	6,378,388 ± 18 metres
eciprocal of flattening	297·0 ± 0·5
olar semi-diameter	6,356,909 metres

he above figures were derived from observations made in the .A. only; and the introduction of the principle of isostasy (*q.v.*) the novel feature of the work. Remembering that the entire .A. area of 3,026,789 sq. m. is but 1/66th of the entire earth's a, 197,000,000 sq. m., some doubt might be felt as to their univer- applicability and their stated probable errors. An independent sideration by Helmert[2] of Hayford's figures yielded probable ors ± 35 metres and ± 0·8. Further, Helmert[3] in 1915, from a cussion of numerous gravity results from places scattered over globe found 1/296·7 ± 0·6 for the flattening, which is a very strong roboration of Hayford's value.

The Reference Spheroid.—That the geoid should be a spheroid s a very plausible conjecture; for a spheroid is a possible indary for a rotating gravitating fluid mass—the flattening ending on the internal density distribution. When a solid ss is considered in place of a fluid mass some modification the resultant form may be expected; at the same time the elopment of isostasy supports the view that the earth be- ves in many respects as though it were viscous, tending to the m it would assume if fluid. However, long before such evi- ice became available, it was tacitly assumed that the geoid s actually a spheroid. Nineteenth century observations were uced by Clarke and others, treating any discrepancies from eroidal form as due to observation error. This was justifiable en data were scant, and the instruments, with which they had n obtained, were of poor precision.

More recent data from greatly improved instruments, how- r, leave no room for doubt that there are measurable differences between the geoid and any adopted spheroid. Geodesists study the actual form of the geoid, expressing it with reference to a spheroid, which is accordingly named the "reference spheroid." When the reference spheroid is in close correspondence with the geoid, the mutual separation is small at all points. This facilitates many computations: for some purposes observed horizontal angles, which are geoidal angles, may be treated as spheroidal angles: as has practically always been done, though in a few cases small correction was really necessary.

The General Origin.—Suppose that the geoidal form were known throughout, and apply to this the international (or any other) spheroid. How is the latter to be orientated? The minor axis of the spheroid may be set parallel to the actual axis of rotation of the earth, whose direction is known unequivocally to the precision of astronomical telescopes. This answers the question of orientation. The location of the spheroid remains at choice. Any point on the spheroid may be brought into coincidence with corresponding point on the geoid; but *only one point can be so treated*, which may be called the "general origin." When this has been done, some portions of the geoid will lie without the spheroid, and other portions will lie within. The two surfaces will intersect in a number of closed curves, on one of which will lie the general origin. The normals to the geoid—verticals—will not coincide with the corresponding normals to the spheroid except at points along certain closed curves, quite distinct from the curves of intersection of the two surfaces. The form of these curves will change if the general origin is changed. The inclination of geoidal and spheroidal normals at corresponding points is what has generally been called the "deflection of the plumb-line." It will be clear now that the deflection of the plumb-line at a point depends on the choice of spheroid of reference and of general origin. It is not an absolute quantity, but dependent on the reference system. When this latter has been selected, there is a unique value of the deflection at any point which has been geodetically connected with the origin. In practice, however, it is necessary to assume separate origins for each detached survey, and accordingly the deflections of surveys on separate origins cannot be regarded as absolute quantities. In this respect the international spheroid cannot be considered as unique as yet.

The Selected Figure.—Meanwhile the study of the geoid in each detached survey may be continued. At any point of the earth's surface, astronomical observations combined with W.T. signals enable both latitude and longitude to be uniquely determined, independently of any assumed reference figure. A number of such points are connected by linear measure and triangulation, and values, called geodetic, of latitude and longitude are computed *on the selected figure*. The differences of astronomic and geodetic values are the deflection components. If these are sufficiently numerous—which may be judged by the smoothness of deflection variation—the separation of the geoid and spheroid can be integrated.

An alternative method of finding this separation is based on the measurement of vertical angles between the triangulation stations combined with spirit levelling and deflection results.

The observed vertical angles are reduced to the spheroidal vertical by application of the appropriate deflections. If the terrestrial refraction[4, 9b], of each ray is computed, it becomes merely a geometrical problem to calculate the differential *spheroidal* heights. Spirit levelling, which with its short rays intimately follows the geoidal surface, yields the *geoidal* heights. Both spheroidal and geoidal heights are thus known, and hence the separation of geoid from spheroid.

Ordinary triangulated heights, uncorrected for the deflection, are not the same as spirit levelled heights, apart from the question of precision; and they certainly are not geoidal heights. Geoidal heights are what enter into practical problems; but from the geodesist's point of view they do not mean much until the form of the geoid, to which they refer, has been determined.

Base Line Measurements.—Modern bases are measured with wires hanging in catenary under constant tension, a system introduced by E. Jäderin of Stockholm. His original plan was to use two wires having different expansion coefficients, whence the temperature could be determined and the necessary corrections applied. With Guillaume's invention of "Invar" this became unnecessary.

A bright wire of small gauge (1·65 mm. is the usual diameter) is not much affected by the sun's radiant heat, and so its temperature does not differ much from that of the air. With the low expansion coefficient of invar, $4\text{x}10^{-7}$ per degree Centigrade, an error of 2°·5 causes an error in length of only 1 in 10^6. The method of using invar

---

Figures throughout the text refer to notes at the end of the cle.

wires has been closely studied by Benoit and Guillaume[5] and their procedure may be confidently followed. It is vastly simpler than the old methods with compensated bars and is also much more accurate; further, much rougher country can be negotiated and so, longer bases become possible.

For the standardisation of wires at the observatory, before and after the measurement of the base, different methods of laying out a length of 24 metres, which is the usual length of the wires, have been employed. An apparatus designed by Sir David Gill for India was fully described in *Engineering* 1915. The ultimate standard of length in this is a nickel bar of H section, one metre long. Standards for ordinary use are H bars of invar, one metre and four metres in length. Invar has been observed to undergo a secular change in length which continues for many years. Investigating this, Guillaume found that the instability is due to the presence of carbon which gradually forms cementite, Fe_3C, with the iron. The addition of chromium, which has a greater affinity for carbon than iron has, prevents this and an invar with ten-fold increased stability has been produced.

Triangulation.—Theodolites with circles of 12 or 10 in. are usually employed for the highest class geodetic triangulation. Mr. Connolly of the India Stores Department considers even that the fullest instrumental accuracy can be incorporated in an 8-in. theodolite fitted with a large objective telescope. Luminous signals, heliotropes by day and lamps by night, are essential. Vertical angles should be taken between 1 and 3:30 P.M., when the refraction is usually a minimum and most regular. None the less there is frequently at this time poor definition, and horizontal angles should be observed at night or by day within three hours of sunrise or sunset.

Control.—Triangulation emanating from a fixed point with observed base and azimuth yields positions of all stations and lengths and azimuths of all sides. Errors are unavoidably generated. Their probable amounts are given by the formulae of de Graaff Hunter[6] now indicated.

These involve the quantity $M=(1+f)m\sqrt{18/l}$, in which l is the average length of side; m (Ferrero's error of mean square of an angle) $=\sqrt{\Sigma(\Delta^2/3n)}$, where Δ is the triangular error and n is the number of triangles; and f, which lies between 0 and 1/6, depends on the type of figures in the series. Further, if O is the starting point and A the station at which errors are sought: R=OA and S=curved distance, OA measured medially through the series, both expressed in units of 100 miles, then P.E. in seconds of azimuth at $A=1\cdot''575\sqrt{\Sigma M^2S}$, P. E. in 7th figure of log. side at $A=33\cdot2\sqrt{\Sigma M^2S}$, P. E. in feet in northing or easting at $A=4\cdot03\sqrt{\Sigma(M^2\int R^2dS)}$.
The summation Σ is in each case for a set of series for which values of M differ.

The first two of these formulae give the means of determining at what intervals control of triangulation is desirable. Clearly an extra base will control the error developed in side length: to control the azimuth it is necessary to form a Laplace point, at which azimuth and longitude are determined astronomically. A numerical example will illustrate the method. It is desirable to introduce a control when the P.E. attains 3 times the error of the control. Two bases are involved, one at each end. If the P.E. of a base is 1 in 10^6 then the P.E. of the control is $\sqrt{2}$ in 10^6. The P.E. of side reaches thrice this amount when $33\cdot2M\sqrt{S}=3\sqrt{2}\cdot10^7\log.(1+10^{-6})$. Taking $M=0\cdot2$, corresponding to very high class triangulation, we find S is 772 miles.

Next, if ΔA, ΔA_o are differences astronomic minus geodetic azimuths; L, L_o, λ, λ_o triangulated values of longitude and latitude of A and O, and T the difference between the local times at A and O, then Laplace's equation is

$$\Delta A_o\text{cosec}\lambda_o-\Delta A\text{cosec}\lambda=(L-L_o)-15T$$

which serves to determine ΔA, a quantity to be subtracted from the astronomic azimuth to give the correct geodetic azimuth. The P.E. of an astronomic azimuth is taken as $0''\cdot2$ for high class work; that of T as $0^s\cdot03$. Hence the P.E. in azimuth determined from Laplace's equation is

$$\sqrt{[(0\cdot2\sin\lambda\ \text{cosec}\ \lambda_o)^2+(0\cdot2)^2+(0\cdot45\sin\lambda)^2]}$$

If we take $\lambda=\lambda_o=45°$ this become $0''\cdot42$ and $1\cdot575\times0\cdot2\sqrt{S}=3\times0\cdot42$, whence S is 1600 miles. If the time error could be reduced to $0^s\cdot01$ the value of S would be almost halved and the precision of azimuth would be about the same as that of side control. It is to be pointed out that there is little gain in controlling the side length with great accuracy while the equally important azimuth control is much less precise. Hitherto the ruling criterion has been that of azimuth. The conclusion is that until time observations are more precise, the highest class triangulation is not likely to be much improved by the controls available unless its extent is considerably greater than 1,000 miles.

Determinations of Height.—The precision of spirit levelli is so great as to justify the recognition of the lack of parallelis of the various level surfaces, each of which is approximat spheroidal. It is nowadays customary in levelling of high p cision to apply to the observed differences of height the corr tion[7,8], for the convergence of these surfaces, that is to sa the orthometric correction; and to publish the orthomet heights. As regards differences of height found by triangulati much improvement is called for. Observed vertical angles are ferred to the local geoidal vertical; they require correction to t reference spheroid vertical, as well as for refraction, after whi the height differences can easily be calculated.

Refraction.—When reciprocal observations have been made two points A_1, A_2, if E_1, ω_1, δ_1 are respectively the angle of elev tion, the refraction and the deflection at A_1 towards A_2, a similarly with changed suffixes for A_2, then

$$E_1+\delta_1-\omega_1+E_2+\delta_2-\omega_2+C=0,$$

C being the angle between spheroidal verticals at A_1, A_2, co puted from the triangulation. The ordinary practice is to igno δ_1 and δ_2 and to assume that $\omega_1=\omega_2=\Omega$; whence $2\Omega=E_1+E_2+$ The ratio $\Omega/C=k$ has been called the coefficient of refractio and as $k=\frac{1}{2}\left(1+\frac{E_1+E_2}{C}\right)$ it can be computed when a ray h been observed at both ends.

There are cases when $\delta_1+\delta_2$ is by no means negligible in co parison with $\omega_1+\omega_2$; moreover there is little justification for t assumption $\omega_1=\omega_2$, unless the two stations are at the same heigh

Refraction has a diurnal change, falling to a minimum about t time of maximum temperature, moreover the value of the minimu is pretty constant from day to day. It is in this constancy that l the value of observing vertical angles between the hours of 1 a 3:30 P.M. Consideration[4,9b] of the physical laws leads to a formu which represents the refraction usually met with at these hour At other hours the refraction is ordinarily larger by an amount whi varies as the defect of temperature from maximum and as the cos cant of the angle of elevation of the ray. The physical cause[10] is t the temperature lapse-rate is nearly constant within the hei limits of the ray, and does not vary much during the day exce comparatively close to the ground. The refractive effect of a pla stratum of air close to the ground can be expressed in terms of t air densities of its upper and lower surfaces. Some confirmation this view is obtained by considering barometric height reading Further research is required, and more observations, with f particulars of local deflection, are needed for investigation. In cas where the data are complete, the refraction does not appear so i tractable as has generally been supposed.

Astronomical Latitudes.—For the observation for latitu the zenith telescope and the Talcott-Horrebow method seem to have superseded all others (*see* 11.610); but the method equal altitudes is worthy of attention. Several special instruments have been designed for this observation, all of whi determine latitude and time simultaneously; whereby in association with wireless time signals, deflection in both meridian a prime vertical can be found.

The prismatic astrolabe of MM. Claude and Driencourt,[11, 12,] which is made in two sizes, has a horizontal telescope with equilateral prism mounted in front of the objective. The edges the prism are horizontal, and one face, that nearest to the objecti is vertical. A mercury bath is suitably placed below and slightly front of the prism. Light from a star of approximately 60° altitu falls normally on the upper face of the prism, and is reflected internally at the lower face towards the lower half of the objective. the same time light from the same star falls on the mercury, is flected into the prism through the lower face, then internally at t upper face, and so to the upper half of the objective. In both cas after reaching the objective, the light is brought to a focus and t images of the star are formed. These approach one another, and t instant at which they pass is timed—this instant corresponding t fixed altitude depending on the angle of the prism, imperfection i the focus of the telescope and the refraction. The actual altitude usually regarded as an unknown; corrected for refraction it should b a constant for one instrument.

Provisional values for this, for the latitude and for the time bein assumed, the result of one observation can be plotted as a straight lin on a chart with time and $\lambda\sec\lambda$ as co-ordinates. Four stars, on in each quadrant, form a set of observations and yield four such line which should touch a circle of radius equal to the discrepancy of th altitude from that provisionally assumed, both multiplied by cos λ. The co-ordinates of the centre of this circle represent the time an latitude sought, and the constancy of its radius is a measure of pre-of the observation. If there is too much wind the partially ed mercury surface is disturbed, and observation becomes im- le. The adjustments are very simple, as is also the observation the observer is practised; and there is practically no recording. utations and preparation of star programme are not excessive. lent results have been obtained with this instrument. In iscussion of a paper[14] Jackson stated that the images are ated, being in reality short spectra; so that stars of different r would give different results. Other users of the astrolabe have und this to be appreciable. Practical drawbacks are that each ields only one observation and that the time estimate is bur- by personality. To overcome the latter L. Favé[15] described ment to measure the personal equation, but up to 1925 this t proved completely successful.

alternative instrument, free from two of the above noted tions is the Circumzenithal Apparatus of MM. Nusl and Fric.[16] is the light from the star enters the instrument through llel plate of glass and falls on a half silvered mirror, being split wo portions. One portion proceeds to a mercury bath, and reflection there and at a second mirror passes again through the ilvered mirror. Thence both portions enter the observing tele- . The mercury is completely screened from the wind. By s of an achromatic reversible prism placed in front of the plate ich light enters the instrument, a star can be observed at three ly different altitudes. An additional interior prism in front of bjective, which causes the formation of four images, allows 7 vations to be made on the same star at each altitude.

imple bent telescope, in which reflection occurs at a mercury has been designed and used by de la Baume Pluvinal. Ob- g 10 stars on the same evening at the Paris Observatory, he ob- values of latitude and longitude differing by $0''\cdot2$ and $0^s\cdot03$ the well established observatory values.

Egypt, Wade has employed a simple method[17] of finding ential latitudes at places a few hundred metres apart.

ngitudes.—Several of the large wireless stations send out al time signals, which can be picked up at very great dis- s by suitable apparatus. These provide a basis for longitude mination when the local time has been observed.

e very powerful station at Bordeaux is an example; and the e times of the signals are determined by the "Service Horaire bservatoire de Paris." The signals are of the "rhythmic" in which 300 dots are sent out uniformly spaced over 293 ds. At the end of the set the precise times of those of the us day are signalled. Very precise comparison can be made by at what exact seconds the incoming signals coincide with the of the observer's clock: alternatively, when a recording er is used, all the 300 dots are recorded and subsequently red. Owing to the time of duration of the signals and of the beats not being precisely equal, there is some personality in timate of instant of coincidence. To obviate this Thrum[18] d a method in which the incoming signals and those of the extinguish one another in the telephone when they overlap. ence of opinion exists as to whether the registration or the on method is the more precise.

ne signals have been picked up at several of the larger observa- day by day for years. Sampson[19] pointed out and dis- serious discrepancies of the order of $0^s\cdot1$ in the relative times. omplete explanation is still to be found. On the other hand ude circuits recently formed by the U.S.C. and G.S. are stated ve closing errors of the order of $0^s\cdot01$, suggesting that field in- ents and conditions are superior to the large instruments and tions at the fixed observatories.

orld project of longitude was put forward by General Ferrié in A mixed commission of the International Unions of Astronomy f Geodesy and Geophysics was formed, and the project has discussed at Rome, 1922, Madrid, 1924, and Cambridge, 1925. ls have been advanced sufficiently for a decision to execute the e in 1926 to be arrived at. It is hoped to fix very accurately ngitude of numerous points over the earth, thus helping to dinate geodetic surveys. At the same time much experience in ghest precision work of this nature will be obtained. A com- nsive account of clock and wireless installations for this pur- s given by the Bureau des Longitudes.[20]

vity.—The absence of means of measuring the "sway" xure of the stand of pendulum apparatus was perhaps the pal cause of uncertainty in the older pendulum observa- Two methods have been devised and used for a number rs; and a further advance in eliminating the effect of sway een made by Vening Meinesz.

he two methods referred to, one is in vogue in the U.S. and ts in actually measuring the movement of the stand by aid of terferometer.[20a] It is claimed that the error in "g" from termination rarely exceeds 2 in 10^7. The other method, due to ann,[21] provides a means of mounting a second pendulum same stand. The first pendulum is set swinging, and from time to time the amplitude of the second pendulum, originally at rest, is noted. Formulae expressing the effect of sway in terms of oscillations are given. The precision appears to be much the same as that of the first method. Both of these methods regard the sway as a constant during the course of the observations at a station, lasting perhaps three days.

Vening Meinesz[22, 23, 24], solves the problem more completely, and also overcomes the effects of earth movements by always employing simultaneously two isochronous pendulums. These are mounted on one stand so that the distance between their points of support is invariable, and are set swinging in different phases. Denoting the angles of elongation by θ_1, θ_2 then the angle $\theta_1-\theta_2$ may be regarded as the angle of elongation of a hypothetical pendulum which is free from the effects of sway; as also of various irregular perturbations. So far is this the case that apparatus so arranged has been used for determining gravity at sea in a submarine; and determinations have been made in Holland in places where the ground is very unstable. Observation is much as usual in pendulum work, the ray of light passing from the mirror of the first pendulum to that of the second and thereby recording the differential angular movement of the two.

In consideration of its success at sea, Vening Meinesz's method supersedes the earlier work of Hecker and Duffield[25] with hypsometers and barometers. The possibilities opened up are very extensive. Helmert's formula of 1901 has been used widely in pendulum work. It is

$$g_0=978\cdot030\,(1+0\cdot005302\sin^2\lambda-0\cdot000007\sin^2 2\lambda),$$

λ being the latitude. Bowie,[26] p. 196, taking isostasy into account, found 978·039 as the equatorial value, and ·005294 as the coefficient of $\sin^2\lambda$, while Couchman[27] found Helmert's value too small by ·011 in the case of Indian stations.

In 1915 Helmert[3] gave a formula involving the longitude L,

$$=978\cdot052\,(1+\cdot005285\pm7\sin^2\lambda-\cdot000007\sin^2 2\lambda$$
$$+\cdot000018\pm4\cos^2\lambda\cos 2(L+17^\circ\pm6)$$

This is based on 3,000 stations reduced by Borass. It implies an elliptic equator with major axis in 17° W. longitude, whose half length is 230 metres greater than the semi-minor axis—compare Clarke's 3-axial figure results, with 8° 15′ W. as the longitude and 465 metres excess length of the semi-major axis.

The Eötvos Gravity Torsion Balance[28] measures the rate of change of gravity. The change per cm. along meridian given by the formula is $8\cdot1\times10^9$ C.G.S. units in latitude 45°; and as the instrument is incredibly sensitive, it is capable of measuring 1×10^9 and less, and easily detects irregularities. Nowadays it is used in prospecting for oil. (*See* GEOLOGY; ISOSTASY.)

GEOGRAPHY (*see* 11.619).—The advance of geography as a subject of scientific study and research in fields other than that of exploration of untrodden ways is largely due to a change in the spirit of the times, which, from a vivid realisation of man's power over nature through his invention of mechanical power-schemes, has swung across to a deep sense of the play of dimly apprehended physical and social influences, which need study for men's sakes.

Within the scientific geographical field special credit must be given to the pioneering work of Réclus in France, to Ratzel and von Richthofen among others in Germany, to Vidal de la Blache and E. de Margerie and their schools in France, to W. M. Davis and others in the United States of America and to A. J. Herbertson in England. The geographer explores the earth and hands over to many specialists the tasks of analyses of geological, meteorological and other data, but he keeps the duty of building up more and more synthetic pictures of the various regions of the world, and he does this especially by studies of the conclusions of structural, physiographical, climatological and biological specialists, and by institution of comparisons of the interrelations of these conclusions as they affect every part of the world. Alongside of this he seeks "exact and organised knowledge of the distribution of phenomena on the earth's surface."

Natural Regions.—He is thus concerned to gain on the one hand general distributional knowledge, and on the other hand synthetic regional vision, the view of interrelations of specialist conclusions with reference to a region. The latter task involves the former, for it is through an appreciation of coincidences of distribution that we are able, scientifically, to recognise a region in geography. Herbertson gave notable service in this direction, for he saw the world as composed of a number of major natural regions within each of which there reigned, for him, partial uniformities of structure, drainage, climate and ecology. Though the progress of knowledge may well alter the relative weights given to different groups of facts, and may thus lead to schemes of natural regions that diverge from Herbertson's, the basic idea, for which he was largely responsible, maintains and develops itself. His major natural regions are, inevitably, almost entirely climatic, and here the problem is relatively simple if we allow enough for transition zones. When the subdivision of major regions is discussed, divergence of view is usually developed, as so much depends on the subjects of election of the disputants.

Physical Geography.—The older form of study of physical features of the earth's surface reviewed matters such as denudation by rain and rivers, coast erosion and deposition of materials, and endeavoured to find types of various natural processes. This type of work has continued, and Dr. Vaughan Cornish has contributed especially to the study of waves. Another physical study has received a great impetus from the publication of E. Suess' masterpiece *Das Antlitz der Erde* (1883–1909). This work, made possible by the researches on mountain structure pioneered for Britain by C. Lapworth, Peach and Horne, gave a glimpse of order, of pattern, in the physique of a country, and turned studies of physical geography in a regional direction, for it was now possible in a far more real sense than previously to see how physical features had come to be as they are. The trend in this direction was encouraged by the prevalence of evolutionary thought at the time. Few fields of research have yielded such harvests in the last generation as have been reaped by the geomorphologists, students of the regional history of the earth's physical features, and advance continues rapid for Wegener's views; and Argand's ideas on the evolution of the mou systems of the northern hemisphere through northward dr Africa, Arabia and the Deccan are valuable as aids to tho whether they themselves stand or fall (*see* GEOLOGY).

Geomorphology.—To geographers, whose business is the thetic picture of a region, the conclusions of geomorpholog of the first importance, for in no other way, save by the stu geomorphology, is it practicable to gain a vivid and underst ing view of the physical features of a region studied. Wit help of geomorphology the physical map becomes a palim in which we decipher numerous superposed patterns of hil valley lines, of basins and domes, of scarps and plains, an superposition of patterns indicates the course of their evolu

Mention should be made, incidentally, of the progre knowledge as to the general factors of the surface history o earth since Fisher's *Physics of the Earth's Crust* appeared in The recent outstanding contributions have been Hayf theory of isostasy (*q.v.*) and Joly's boldly interesting speculat These researches are bringing with them a vision of law order in the formation and evolution of characters of the n regions of the earth's surface of both land and water.

To the work of Suess are naturally related the studies of reefs and their origins initiated by Darwin, and continue many workers. Deperet has studied the ordering of coastal races around the Mediterranean, and a body of knowled coastal plateaus and of their relation to fluvial and fluviogl terraces is growing up, especially for Europe and North Ame It still needs more detailed comparisons to be made, but alr promises to spread the idea of orderly changes as a key t interpretation, on evolutionary lines, of a large range of su features most important in the landscape.

We note also the continuation of the work of Penck an followers on glaciers and moraines in the Alpine regions, of of de Geer and his students in Scandinavia, and of the exten of this work by Dainelli to the Himalaya and by Renngart the Caucasus. The effects of the phases of the last great ic on the landscapes of the northern hemisphere are thus beco known, especially as American workers have brought out pa studies for their continent. This work may be said to have a from the pioneer studies of James Geikie.

Oceanography (*q.v.*).—Studies of physical conditions in oc and seas have progressed largely owing to the efforts of com sions investigating fisheries. Schmidt's description of th history and migrations of the eel was an outstanding advance. DISTRIBUTION OF ANIMALS.) As an example of some bea of this work on geographical synthesis may be mentioned work of O. Pettersson on the hydrography of fiords and part enclosed seas around Scandinavia, in which he suggests se variations of tidal power as factors of changes of climate time to time.

Meteorology (*q.v.*).—In climatic study we note J. G. Bartholo and A. J. Herbertson's *Atlas of Meteorology* (1899), the wo Lyons and others in Egypt, and that of the British Met logical Office in preparing tables of normal figures for cli facts, and Dr. G. C. Simpson's theory of the Indian summer soon published in 1921 are notable. The study of the genera tribution of barometric pressure and of its changes in cyc systems is associated in England with the name of Napier S and there has been a great increase of knowledge of the lay of the atmosphere and of its more detailed conditions at diffe levels connected with the development of flying-machines the mapping of air-routes. The many new facts and views tained are modifying very seriously our expositions of fa of the climates of the earth's regions, and here again a s position has by no means been reached.

Climatology.—Climatological researches in polar regions been of great value for better understanding of climate where. C. E. P. Brooks, Berg, Murgoci and others have tri argue from the present to the climatic conditions of the past, have thus contributed factors of interpretation of variou and other features of the present day; von Richthofen pione in this direction with his classic work on Loess. (*See* CLIM

:ology.—Ecological study of plants (*see* Ecology), animals
man is both geographical and biological, the former in so
:s it works out features of the place inhabited, and it is indeed
:times argued that geography is essentially human ecology.
ıis field there has been increasing recognition of the fact that
lora and fauna of a region represent no more response to pres-
:onditions, but result from accumulation and interference of
t of a long series of past changes. In many cases, such as that
ıe virgin equatorial forest, a complex and delicate balance
'e has been established through the course of ages, and these
ıts will probably not regrow in anything like their present
. if cut down. The work of de la Bathie on Madagascar
ght this out specially. Several opinions concerning plant
animal distributions need adjustment if newer views on
inental drifts and on climates of the past are established.

:gional Studies.—Another generation saw the appearance of
ge number of studies of regions based upon scientific data.
Richthofen's *China* is rather old in parts, but its influence has
widely extended. Vidal de la Blache's *Tableau de la Géo-*
hie de la France (1903), like F. von Richthofen's *China* (1887–
), emphasises the facts of structure most of all. J. Dantin
:ceda's work on Spain, in turn, emphasises rather the facts of
ate and ecology. The volumes of the Filippi expedition to
Himalaya are conceived in an encyclopaedic spirit, but as
t is too early to say whether much effort will be made to-
ls synthesis. The American Geographic Society began a
s of scientific studies chiefly on Latin America. Sir M. A.
ı's *Serindia* (1921) is another encyclopaedic work with the
hasis largely on cultural distributions. A. Philippson's *Mit-*
:ergebiet (1914) may be used as an example of a less ency-
ıedic type of work which nevertheless effects with some suc-
a synthesis of a large number of scientific facts. The Atlas
inlande is another type of the collection, and to some extent
synthesis of scientific data, this time concerning a state.
ıughout these works it will be seen that the geographer's
ial part is to correlate specialist data and to synthesise the
into a picture of the region.

eat services have been rendered to the science of geography
vriters on various regions whose main object is a somewhat
rent one. H. W. Bates' "Naturalist on the Amazon" (1892),
son's works on La Plata (1892) and C. M. Doughty's
ıbia Deserta" (1888) are typical examples in this connection.

aps.—The map (*q.v.*) is the geographer's special instrument
he must work at its improvement, both as a representation
rger or smaller parts of the earth's surface and as a record
ecial types of data. The War provided enormous oppor-
:ies for surveying and cartography, and remarkable results
also attained by mapping from aerial photographs (*see*
veying). Different tints in turf brought out unsuspected
on development of the negative and led to interesting dis-
ries. (*See* Archaeology: Air Survey.) The mathematical
ry of map projections has been advanced especially by A. E.
ıg in England and Adams and Deetz in America. The "One
Million" map, on the other hand, met some difficulties on
ay towards the goal of world-wide unity; political reasons
o the crowding of some sheets with names while others
left nearly blank. Sheets including frontiers led to troubles
een states in some cases, and the wave of nationalism after
War thus harmfully affected for the time what promised to
great step forward in scientific geography. The Italian
raphers issued an interesting collection of map sheets
ing typical examples both of physical features and of
ın occupation of the surface.

mography.—The mapping of various types of data has en-
l much attention. General poverty after the War largely
ed improvement of the topographical map. The demo-
ıic map, fundamentally giving distribution of population is
n a state of flux. It is generally felt that density of popula-
cannot be adequately marked by contours, and, both in this
er and in that of mapping commercial production, the meth-
stippling with fine dots has been tried, while Sten de Geer
ıcted experiments utilising large circles, etc., for the purpose of indicating agglomerates. The mapping of data has spread remarkably as an auxiliary in many fields of study, such as ethnography (*see* Folklore), archaeology, anthropology, history and commerce. In most of these cases the stipple and contour methods of representation are rivals, while new methods tend as much towards insuring graphical power as towards accuracy of detail. The growing tendency to display on any one map only appropriately related facts is a testimony to the acceptance of the map as an instrument of research. The maps in C. Fox's *Archaeology of the Cambridge Region* (1923) illustrate the development of this point of view. (*See* Map.)

Place Names.—On the border line of geography is to be noted especially the development of the study of place names under Longnon in France, the English Place Name Society in Britain, and the effort of the British Permanent Committee on Geographical Names towards standardisation. (*See* Philology.)

GEOLOGY (*see* 11.638).—The progress of geology suffered from a four years' break, which provided, however, a stimulus to economic geology by the compilations on mineral resources required during the peace negotiations, and to monographs on little-known areas such as the war fields (*Die Kriegsschauplätze 1914–1918 geologisch dargestellt*, Berlin, 1923–5).

The accumulation of geological evidence has increased apace owing to the foundation of new universities, the fuller educational employment of research work and the wider recognition of the economic value of geology. Its literature has become overwhelming, while its bibliographies and indexes are less efficient owing to the increasing bulk of material and cost of publication. One of the urgent needs in geological development is co-operation between the agencies which publish synopses of literature to secure prompter and fuller references and less serious omissions.

In the progress of geological philosophy since 1910 three features have been especially remarkable. First, the lessened over-emphasis on the geological conditions of northwestern Europe and the eastern states of North America, with the consequent abandonment (*cf. e.g.*, G. A. J. Cole, *Rep. Brit. Assoc.*, 1915) of that ultra-uniformitarianism which had developed in those countries. Second, release from the restricted range of geological time that had been declared necessary from physical and mathematical data. Instead of a possible maximum of ten million years, as maintained by Tait, geologists are at liberty to assume 8 to 10 thousand million years, and need not discard hypotheses which demand prolonged time for minor geological phenomena. Third, recognition of the plasticity of the earth's crust, and of the world-wide effect of earth movements on the relations of land and water. The physical evidence has been found to afford a more precise correlation at some dates than that based on fossils. The belief in the plasticity of the crust and the lateral movement of the land masses has led to the study of mountain ranges and crustal movements with renewed zeal, and to a flood of speculative hypotheses which are perhaps a reaction from the mental strain of the War.

Origin and Constitution of the Earth

The discussions on the origin of the earth have marked the steady wane of the nebular hypothesis of Laplace. The hypotheses which are replacing it agree in accepting the solar system as derived from one aggregation of matter; but they attribute its start to the tidal disruption of the parent mass by a passing star. This theory has been put forward in various forms. Its modern development is based upon the planetesimal hypothesis, which has been restated by T. C. Chamberlin in his *Origin of the Earth*, 1916 (and in *Jour. Geol.*,[1] Chicago, 21–29); it has been adopted by J. H. Jeans, *Problems of Cosmogony and Stellar Dynamics*, 1919, and Harold Jeffreys, *The Earth*, 1924.

According to Jeans the parent mass extended throughout the range of the solar system, while according to Jeffreys it was restricted to the inner part. The material of the earth on each of the theories was once loose and was welded by heat due to collisions or pressure. That the original material was gaseous is urged by Eddington, since so many stars have the size appropriate to a gaseous body; but that the earth was constituted by the aggregation of solid meteoritic material agrees with the well-established facts of the earth's high internal heat, zonal structure, and composition. The planetesimal theory has undergone important developments and modifications in recent memoirs by its founder, T. C. Chamberlin. He calls attention (*J.G.*, 28, 1920, pp. 144–6) to the possibility of the planets still receiving matter from the sun, in consequence of such solar explosions as those which in May and July 1919 hurled material to the height of at least 475,000 m. above the sun's surface, and probably outward to the orbits of some planets.

The planetesimals, according to Chamberlin's estimates of 1920 (*J. G.*, 28, pp. 672, 681; 29, pp. 407–8) were originally very minute, and weighed about one-fiftieth of a pound apiece; amongst other phenomena he attributes to them the zodiacal light and Saturn's rings. He compares them (*J. G.*, 29, 1921, pp.407–9) with the chrondrules, the rounded grains found in meteorites, rather than with the meteorites themselves. They therefore approximate to the meteoritic dust, which, according to T. J. J. See, was once spread throughout space. In spite of the small size of the planetesimals Chamberlin regards them as having contributed two-thirds of the mass of the earth by their fall from space as rain upon the original core (*J. G.*, 28, p. 681). Jeffreys, however, denies the possibility of any great accretion of such material, and dismisses the planetesimal hypothesis as no solution of any of the main problems of geophysics, and as quite unacceptable on cosmogonic grounds. He has brought it forward in a modified form, which, according to Chamberlin (*J. G.*, 32, 1924, p.713), accepts all the essential doctrines of the planetesimal hypothesis.

Meteoritic Theory.—Lockyer, the founder of the meteoritic theory, recognised that many of the meteorites which formed the earth had planetary orbits, and that they came from a single source or zone is supported by the work of Sir William Crookes (*Phil. Trans.*, 1918, vol. 217A, pp. 427–30). According to Crookes the stony meteorites consist of the elements which form the bulk of the earth's crust, and he suggests, from the striking simil in the proportions of their four chief constituents, that they all derived from the disruption of a planet that once existe tween Mars and Jupiter; the nickel-iron meteorites may have derived from the core of the same planet, or may have come a different source. The chemical similarity of the core of the e to the iron meteorites is asserted by L. H. Barnett (*J. G.*, 32, pp. 615–35) as according to him the core consists of 90% 7% nickel, cobalt and copper, and 3% of the other eleme The elementary constitution of the earth has been recalcul and its agreement with a meteoritic composition follows Tamman's (1924) estimate that 98% is composed of 7 elem in the following order of abundance—iron, oxygen, sili magnesium, nickel, calcium and aluminium; four othe sulphur, sodium, chromium and potassium, constitute ano 1.6%; all the other elements together amount to only four p per 1,000 of the substance of the earth.

The stony meteorites, so far as is known, correspond onl the basic igneous rocks. The occurrence of acid meteorites been claimed from the obsidianites of Australia, but microscopic structure indicates their formation as aerial gurites by the fusion of dust by lightning during dust storm

Zonal Structure of the Earth.—The earth consists of a serie layers, and much light has been thrown on their constitution thickness. The bulk of the earth consists of a nickel-iron m the barysphere, which is enclosed by a rocky crust, the li sphere. Within the barysphere is a core, 1,600 m. in diame which, according to the late C. G. Knott, is fluid, as it does transmit distortional waves. In spite, therefore, of the repeated conclusion that the whole earth is solid, seismol proves this large central core to be fluid. Between the barysp and the lithosphere, moreover, according to various authorit is a weak plastic layer, the asthenosphere of Barrell (*J. G.*, 1914), or the fluid layer of basalt glass which, according to (*Amer. Jour. Sci.*, 1923, pp. 347–71), lies below a holocrystal rigid shell 25 m. in thickness.

The lithosphere has been subdivided into various zo Suess adopted two: the basic Sima, composed predominantl silica and magnesia, and the lighter, more acid Sial, compo predominantly of silica and alumina. V. M. Goldschm (*Geochemische Verteilungsgesetz der Elemente, Vid. Selsk. S Math.-Nat. Kl., Kristiania, 1923–24*) considers that the nickel- core is surrounded by a sulphide and oxide zone which is c parable in metallurgical operations to a matte; above that zone is a stony zone which is comparable to a slag, and is divided into a lower layer of dense silicates, and an upper la of light silicates and silica. E. D. Williamson and L. H. Ada (*Jour. Washington Acad. Sci.*, vol. 13, 1923, pp. 413–28) div the lithosphere into three zones; the lowest consists of hea silicates mixed with nickel-iron and is comparable to the mete ites of the Pallasite type; this layer passes down into the ba sphere and upward into heavy silicates, which are covered b shell of light silicates and silica.

That the barysphere is composed of nickel-iron was affirmed Milne from the acceleration of earthquake waves, toward wh it behaves as a rigid material; but under the influence of intense heat and pressure, the material must at that depth capable of flow into any cavities like a fluid, so that it been described as elastico-rigid, or 'fluidible.' The work of F. Adams (*J. G.*, 20, 1912, pp. 97–118) has shown that the e mates of Van Hise as to the depth at which all rock mate would be fluidible must be extended; for Adams, by an exp ment suggested by Sir Charles Parsons, found that small cavi remained open for months in a granite cylinder which was la ally supported at conditions comparable to those in the ear at a depth of 11 miles. These experiments, however, deal o with a short period and small cores in a rigid case; they do represent the conditions of large masses acted upon by imme pressure at a high temperature for long periods. The h rigidity of the surface of the earth against tidal deformati was supported (*J. G.*, 27, 1919, pp. 585–601) by the observati of Michaelson and Gale on a horizontal waterpipe 502 ft. lo he limited depth of the lithosphere and the constitution of barysphere of nickel-iron have been supported by the evi-ce of radioactivity, for the earth's activity is of a strength ch can be explained by the restriction of radioactive ma-als to a depth of about 40 miles. The material of the nickel- meteorites is the only non-radioactive substance that is ly to form a considerable part of the earth. The inner earth ssigned a more moderate temperature than formerly; that he primitive sun, according to Jeffreys, cannot have been than 3,000° C., but within the earth the maximum may be h lower, for the temperature may be nearly uniform in such a conductor of heat as the nickel-iron core.

The Depth of Earthquake Origins

nowledge of the physical nature of the earth's interior has e most progress from investigation of earthquakes, most which have been attributed to a depth of 5 or 6 m.; Dr. ham (*Quar. Jour. Geol. Soc.*, 78, 1922, p. 57) concludes that great majority arise less than 10 m. from the surface. Lately, ever, physicists have assigned their origin to much greater ths. The late G. W. Walker (*Rep. Brit. Assn.*, 1917, pp. 13–4 *Phil. Trans.* A.222, 1922, pp. 45–56), from the angle of rgence of earthquakes recorded by the Galitzin seismographs ulkova, inferred that some originate at least 800 m. deep. s deep-seated source has been supported by Prof. Turner *p. Brit. Assn.*, 1923, pp. 283–6) who assigns the majority to a e bounded below at a depth of 145 m., and some to a depth oo m., such as the Formosa earthquake of April 14 1906, at miles.

arthquakes.—The word earthquake originally meant a shaking uaking of the earth which could be felt, might cause damage and occasionally accompanied by changes in the aspect of the sur- of the earth. Seismology was the department of science which t with these disturbances, and was naturally regarded as a minor ion of geology; with improved methods of observation and the ntion of special instruments the scope of this subject has been rged, and it has come to include much that does not belong to hquakes in the original sense of the word, or to geology, yet ot be entirely separated. Recent developments in the study of earthquake, which might be dealt with here, are, therefore, sferred to the article EARTHQUAKE.

he shallow origin of some earthquakes was concluded by ne from the twisting and breaking of telegraph cables by slips aterial down submarine slopes. It has been found that such ks are not recorded on seismographs, so that they cause no espread vibration in the underlying rocks. The main claim the superficial origin of a world-shaking shock, other than se due to volcanic explosions, is that by the late Prince itzin, who referred an earthquake, on Feb. 18 1911, to a land- in the Pamir. A mass of earth weighing 7,500,000,000 tons into the valley, buried a village and all its inhabitants, and ned a bank over 3 m. long and 2 m. wide, and a lake 15 m. and 900 ft. deep. Dr. Oldham in a rediscussion of the lence (*Quar. Jour. Geol. Soc.*, 79, 1923, pp. 237–45) has shown the landslip was a result of the earthquake and not its se, for it was not above the centre of the disturbance, which ssigns to a depth of 30 miles.

Volcanic Action

olcanic studies have been greatly advanced by work at the ervatory on Kilauea in the Hawaiian Islands under the ction of T. A. Jaggar. His weekly letter enables geologists ll parts of the world to follow the changes in that instructive ano. Its cauldron was enlarged by huge subsidences in 1919, and 1924, the last being associated with powerful ex-ions.

he destructive eruption of Vesuvius of 1906 has been de-bed by Perrett (*Publ. Carnegie Institute*, No. 339, 1924), shows that the weight of the lava in the throat of the vol- broke through the wall, and the relief of pressure on the en rock enabled its superheated water to explode; the ex-ion threw up a column of vapour 7 m. high and produced anches of hot volcanic sand like that from Mt. Pelée, which whelmed St. Pierre, the capital of Martinique, in 1902. The Pelean eruption has been further brought into line with ordinary volcanic phenomena by the eruption of Katmai, at the base of the Alaska Peninsula, in June 1912—the most notable volcanic event of recent years. Katmai is an old volcano of basic andesite resting upon Jurassic sandstones. The eruption was of the paroxysmal explosive type. It scattered 5 cu. m. of pumice and scoria over the district, depositing a layer a foot thick even 100 m. away. The eruption left a great hollow with numerous steam vents on its floor; the summit of the mountain was replaced by a pit 2½ m. wide, and from 2,000 to 3,700 ft. deep. This crater was at first attributed to the explosion, but C. Fenner (*J.G.*, 28, pp. 569–606, 1920) shows that it was due to subsidence, aided by the solution of the older andesites by the 1912 lava.

The eruption is explained as due to the intrusion of a sheet of rhyolite under the volcano. The intrusion shattered the overlying rocks and the rhyolite rose through the fractures. The Katmai obsidian, when heated, froths up to pumice, and when it reached the surface it was blown into fragments by its superheated steam. This eruption has explained two phenomena of the West Indian eruptions of 1902 that had appeared unique. Part of the Katmai area was covered with beds of sand, composed of pumice that had been pulverized by the explosive escape of the steam. This sand is of the same nature as the incandescent dust which fell in an avalanche upon St. Pierre. A new secondary peak named Nova Rupta was formed at Katmai by the forcing of a dome of rhyolite into the overlying rocks; it is similar to the lava spine which was pushed up through the vent of Mt. Pélée.

Volcanic Cauldrons.—The first report that the great cauldron at Katmai was due to an explosion, threw doubt on the origin of some volcanic basins that had been attributed to subsidence. J. S. Diller (*J. G.*, 31, pp. 226–7, 1923) has restated the evidence proving that "Crater Lake" in Oregon lies in a basin due to subsidence. It is therefore a cauldron. This origin has been attributed to some huge volcanic basins in East Africa, such as Menengai in Kenya Colony, and Ngorongoro which has been further described by Barns in his *Across the Great Crater Land* (1923). Mount Aso in Japan remains by a little the largest known cauldron, being 14 m. long by 10 m. wide (Anderson, *J. G.*, 16, p. 499, 1908). Still larger subsidences form sunklands in some of which, such as the Riessenkessel in southern Bavaria, the sunken rock, there a shattered granite, is surrounded by a ring of lava. The ring-shaped intrusion of syenite, 16 m. in diameter, at Pilansberg in the Transvaal, described by W. A. Humphrey (1914), represents the deeper part of such a formation. The importance of such ring-dikes in volcanoes has been shown in the island of Mull in western Scotland. Its central mountains are the deeply dissected foundation of a volcano of the first order; and the tendency of lavas to rise along circular fractures is there well displayed and has been described in *Geological Survey Memoir* (by E. B. Bailey and others), which confirms the view of Judd that the ancient volcanoes of the Western Isles were separate volcanic vents.

Plateau Eruptions.—That some of the Mull lavas were ejected by fissure eruptions is still advocated, but this origin is not shown for any lava left on the island.

Knowledge of the vast lava fields that have been attributed to fissure eruptions has been extended for those in South Africa and South America. Those in South Africa have been described by Du Toit, "Karroo Dolerites of South Africa" (*Trans. Geol. Soc. South Africa*, 22, pp. 1–42), who shows that the Stormberg lavas (of which the age is Rhaetic or Liassic) cover an area around Basutoland 350 m. long by 150 m. wide. A surrounding area of some 320,000 sq. m. is seamed by dolerite dikes, so that the volcanic area was doubtless more extensive than it is now. C. L. Baker, "The Lava Field of the Barana Basin, South America" (*J.G.*, 31, 1923 pp. 66–79), points out that the basalt flows there cover an area of 300,000 sq. m. with an average thickness of 1,000 ft.; and the surrounding country, to the extent of 75,000 sq. m., is penetrated by innumerable sills and dikes of dolerite. These South American eruptions are of the same or of approximately the same age as those of South Africa—namely, at the very beginning of the Jurassic.

Meteoritic Impact Crater.—The view that Coon Butte or Meteor Crater in Arizona was due to the impact of a great meteorite has failed of further support by the explorations of D. M. Barringer. It was suggested that the crater was made by the nucleus of a comet instead of by a single meteorite. Recognition that this body struck the earth obliquely led to a fresh search for the meteorite under the southern rim of the crater and not, where previous borings were made, under the centre. Recent boring found only country rock.

ISOSTASY

The most significant discussion of the period has been upon the extent of isostasy, *e.g.*, *Bull. Geol. Soc. Amer.*, 33, 1922, pp. 275–410 (*see* ISOSTASY). The evidence for the greater density of the rocks below the oceans has been strengthened by pendulum observations in a submarine. This high density, according to F. P. Shephard (*J. G.*, 31, 1923) may be due to compression. The view generally adopted is, however, that the rocks below the oceans consist of denser material—the sima. Since the ocean floor must consist in places of sunken continental rocks, the existence of sima so near the sea bed appears uncertain.

Isostasy explains how large areas of the earth's crust may be uniformly uplifted, though the possibility of such a movement was denied by Suess. Burrard (*Prof. Pap. Survey of India*, No. 12, 1912, p. 6) has, however, supplied an instance in which 5,000 sq. m. of country between Saharanpore and Mussurie in northern India were upraised 5 inches during an earthquake. This fact was proved by re-levelling a line that had been surveyed shortly before the earthquake.

AREAS OF TENSION

Areas that are being slowly upraised are torn by tension clefts and broken by normal faults. Faults so weaken the rocks they traverse that the side left upstanding is usually reduced to a gentle slope; nevertheless some recent faults in areas of hard rock are marked by fault-scarps which bound sunklands and rift valleys. Of the latter the greatest extends from Palestine across East Africa, and as shown by Teale and Wilson (1915) south of the Zambezi. Its geology has been described by Gregory (*Geology and Rift Valleys of East Africa*, 1921) and Krenkel (*Bruchzonen Ost-Afrikas*, 1922). That this valley had a longer history than was originally recognised by Suess is now admitted. E. Lehmann (*Zeit. Vulkan.*, Erg. 4, 1924) has described the volcanic area in the Rift Valley north of lake Nyasa and shown that its rocks are alkalic in composition. The tectonic origin of the Gulf of Suez, a branch of the Great Rift Valley, has been proved by the Petroleum Bulletins of the Geological Survey of Egypt, and Prof. Brock has confirmed that view for the Dead Sea (*Quar. Jour. Geol. Soc.*, 75, 1919).

Abendanon, as a corollary to his view of the radial contraction of the earth, considers that some parts are forced upward by the subsidence of others, and that tension in the rising parts gives rise to rift valleys. W. H. Bucher, (*J. G.*, 32, 1924) has illustrated the importance of tensional structures by model shells in which the plan of the crumpled bands of the earth are produced by tension and not by compression.

The deformation of the earth leads to wide areas of subsidence and uplift. Thus the subsidence of an ocean floor, by forcing the material below it to flow outward, may uplift its borders. Where the uplifted area consists of hard rocks, the surface will be torn by a network of tension clefts forming fiords and fiord-valleys (J. W. Gregory, *The Origin and Nature of Fiords*, 1913). The upheaval of these areas accompanied great subsidences that followed the crumpling of the earth's surface during the mountain formation which culminated in the Miocene. Where the surface consists of soft rocks the rupture may control the topography, as in the rectangular valley system of north-eastern France, and S. W. Wooldridge (*Proc. Geol. Assoc.*, 34, 1923, pp. 175–92) suggests that many topographic features of the London Basin were determined by intersecting fractures in the underlying platform of old rocks. The tectonic origin of the Greenland fiords has been supported by L. Koch (*J. G.*, 31, 1923, pp. 42–65) who points out that some of the fiord valleys are pre-glacial, w others are of very late origin and have been but slightly fluenced by denudation. These fiords he calls fracture-fiord they were formed by the cleavage of gneiss along plane fracture.

AREAS OF COMPRESSION AND FOLD MOUNTAIN CHAINS

Alpine Structure.—Intense compression of the crust prod fold mountains, the study of which has been especially acti the Alps. It has long been known that some of the northern consist of blocks of old rock resting on younger beds. T "Klippe," or "mountains without roots" have been pu sideways on to their present foundations, a process demonstr in the north-western Highlands of Scotland. There, in s cases, the rocks were broken into short slabs which were fo one over another, giving rise to the "imbricate" structure, as would be produced if a row of slates on a roof were pressed a shorter space. In Switzerland the process has taken place great scale, and successive slabs of rocks have been thrust over another as *Decken* or overthrust-sheets.

In some parts of the Alps this structure is indisputable, bu others the evidence depends on an uncertain identification of rocks. Thus Monte Rosa and the Matterhorn have been in preted as pinnacles of old rock thrust northward over the T The Triassic age of the underlying rocks is uncertain; and tradition dating from the time when many of the Alpine sc were regarded as Jurassic. Bonney's work in the Lepontine showed that the so-called Jurassic schists, like the Carbonife "fossiliferous gneiss," were beds composed of schist debris; were infolded amongst the ancient rocks. The pre-Palaeo age of the crystalline schists of the Alps is now generally adop and the Triassic age of the base of Monte Rosa and the Ma horn is uncertain. The supposed overthrust parts of those m tains have no similar rocks to the south, so that they must h been transported from afar; and some advocates of the extr Decken theory regard parts of the overthrust sheets or "napp as African in origin. This view is dismissed as fantastic "U nappismus" by some Alpine geologists, and has led Heritsc describe the Decken theory as a fantasy.

The distance to which sheets of rock can be thrust is lim by their crushing strength. According to A. C. Lawson mechanical limit of overthrusting must be between 20 and 3 and Oldham has adopted a limit of about 5 miles. An overth of 150 m. has been claimed in Scandinavia but appears impos and is unnecessary on a more probable correlation of the ro The Decken theory in its extreme form may prove untena Amongst the voluminous literature on the theory reference be made to Albert Heim's work, *Geologie der Schweiz* (1918– to the case for it by R. Staub, *Der Bau der Alpen* (1924); f critical view to F. Heritsch, *Die Grundlagen der alpinen T tonik* (1923).

The investigation of Alpine movements has shown that t began earlier than was realised. The movements culmin in the Oligocene and Miocene; but the preliminary buckling gan early in the Mesozoic. Increasing importance is attache the younger granites of the Alps, to which fresh attention been directed by Steinmann. Movements of the Decken typ the southern and eastern Highlands of Scotland have been vocated by E. B. Bailey (1910–25); but his interpretation not been generally accepted.

The Decken theory of the Alps agrees in one respect Suess's interpretation, by attributing the main folding to pres from the south. That direction of movement has been reje by L. Kober, *Bau und Entstehung der Alpen* (Berlin, 1923), denies the asymmetry essential to Suess's view that the Alp belt has been pushed northward and buckled against the resist masses of Central France, the Black Forest, Bohemia and Russian Platform. Kober regards the Alps as symmetrical; explains Alpine mountains as due to a belt of the crust be crushed between the continental coigns, as they are forced gether by the earth's contraction. He regards the Mediterran basin as one mountain block or "orogen," which has be

mpled between northern Europe and North Africa, the move-
nts being outward from the compressed belt and therefore
thward in the Alps and southward in the Atlas. In the Atlas
pre-Alpine folds are southward; but those of the Alpine
iod, according to Gentil, are northward. That direction is in-
isistent with Kober's requirements. Longwall has pointed
that the structure of the Sierra Nevada of California is also
onsistent with Kober's explanation of the Rocky Mountains;
l Hobbs has rejected the theory for the Asiatic Arcs, which he
ributes to deep-seated pressure from the rear or concave side.

he Contraction of the Earth.—The view that mountain folding
lue to the compression of a contracting earth has been further
cussed; arguments against it have been stated by Sandberg
24) and Keith (*Bull. Geol. Soc. Amer.*, 34, 1923); but it has
n more widely adopted owing to the recognition of the fallacy
some objections. It was claimed that the utmost possible
inkage of the earth was inadequate for the observed com-
ssion; that view was based on the limited age of the earth, but
h the multiplication of its age 10 or 20 times that argument
become invalid. Jeffreys has pointed out that shrinkage by
ling would be sufficient, and there are other even more
ent factors of contraction. T. C. Chamberlin has supported
shrinkage of the earth's crust from the greater density of the
th as compared with the moon. If both originally consisted
similar material, the higher specific gravity of the earth is due
condensation, and to the shrinkage of its circumference by
55 miles.

The number of mountain chains in which overthrusting is rec-
nised has been increased, as by the work of Deprat in Tonkin
l southwestern China (*Mem. Geol. Serv. Indo-China*); his con-
sions in this respect have been confirmed by Jakob. Over-
usting has been recognised in the areas between Indo-China
l the eastern end of the Himalayas in northwestern Yunnan
hil. Trans., vol. 213B, pp. 171–298, 1925). Other mountains,
vever, though folded, show but slight overthrusting. Thus the
des, though gently folded in the Upper Cretaceous and
cene, have subsequently undergone block faulting without
ust planes, as shown by Steinmann (*Geol. Rundsch.*, 1922)
sworth (*Geol. North-West Peru*, 1922), Douglas (*Quar. Jour.*
l. Soc., 1914, 1920, 1921) and H. Backlund (1923). Different
ts of one mountain system may have been affected by both
es of movement; thus the northern Rocky Mountains are
wn by Mansfield (1923) to have undergone intense lateral
npression, while Lee (1923) and R. T. Chamberlin (1919)
wed that the movements in the southern Rockies were vertical.

Varrow U-shaped Fold-lines.—Suess explained some important
ographic features by the fold-lines having been diverted in a
rpin-bend, in Assam, the Caribbean Islands, the South
orgia arc in the South Atlantic, and the Moluccas to the west
New Guinea. This view has been adopted by Hobbs (1925)
l extended for the Moluccan Arcuate fold by G. A. F. Molen-
aff and H. A. Brouwer (1921); but the evidence for these
rrow U-shaped bends is inadequate, as the main Himalayan
e of Assam continues eastward into South China; the rocks of
ith Georgia are fundamentally different from those of the
des; in the West Indies the contorted foundation of Barbados
ikes west to east almost at right angles to the supposed arcuate
l; and in the Moluccan islands the essential strike is across the
ection of the chain, and the depression to the west may be due
a foundered block.

gneous Rocks and Earth Movements.—That distinctive series
igneous rocks are associated with different types of earth
vement has been reaffirmed by Harker (*Address, Geol. Soc.*,
7), but has not been generally confirmed (see for example
ewinsson-Lessing, *Bull. Geol. Soc. France* (4), 23) from the
ssian evidence, and for the Australasian area (*cf.*, *Scientia*,
1912, pp. 56–63).

The nature of the intrusions of the great plutonic masses has
n discussed by Daly in his *Igneous Rocks and their Origin*
14), with many luminous suggestions. Hans Cloos of Breslau,
n work in southwest Africa and Silesia (*Der Mechanismus
vulkanischer Vorgänge*, 1–21, and *Abh. Preuss. Geol. Landesanstalt*, n.f. 89, 1923), rejects Daly's theory that the granite masses eat their way into the crust by assimilating the material they replace. Cloos, agreeing thereby with Suess, concludes that intrusive granite either forces the rocks apart or occupies spaces made during the subsidence of blocks of the crust. Some assimilation naturally occurs on the margin, but Cloos regards it as only a minor incident. According to him the direction of pressure during the intrusion and consolidation of the granite may be inferred from the rifts, joints and dikes in the granite, which are parallel to the general grain of the country. The foliation in the granite he regards as less important, as it expresses only the local pressure.

STRATIGRAPHICAL GEOLOGY

In stratigraphical geology the national Geological Surveys and private workers in all countries have been collecting an immense accumulation of new data. The most notable addition to the Geological Surveys is that of China, which, with the new Geological Society of China, have together made a great contribution to knowledge of that country. Among the principles of stratigraphy the problem whether geological evolution has been even and continuous, or periodic by alternate rapid developments and long intervals of repose, has been further discussed. Shepard (1923) insists that the rate of progress has been on the whole regular; but advance by periodic spurts has received wide support, as from T. C. Chamberlin (1921, etc.), R. T. Chamberlin (1914, 1921), G. Stille, *Die Schrumpfung der Erde* (1923) and Prof. J. Joly (*Phil. Mag.*, 1923, pp. 1167–88) and *Surface History of the Earth* (1925) from his theory of the periodic re-melting of the foundations of the crust by radioactive heat; and also from the distribution of land and water by tetrahedral deformation of the crust and its spheroidal recovery.

The classification of the pre-Cambrian rocks has made much progress, especially in Canada, though there is no general agreement in the nomenclature. The tendency is to subdivide the pre-Palaeozoic rocks into a lower division of gneisses and coarse schists, an intermediate division of strongly metamorphosed sediments, and an upper division of sandstones, which are but little altered and may contain traces of organic remains. Some of the pre-Cambrian limestones, which are especially abundant in the middle division, are often attributed to an organic origin; but the extensive chemical precipitation of carbonate of lime has become more apparent, and some oölitic structure is inorganic as shown by its artificial formation (*e.g.*, Johnston and Williamson, *J. G.*, 24, 1916) and the crystalline structure of some recently formed oölite; Van Tuyl (*ibid.*; pp. 792–7) on the other hand shows how oölites with an organic structure may lose all traces of it.

In stratigraphical geology the process has been especially important in regard to the pre-Palaeozoic and the Palaeozoic. Much work has been done by many British geologists on the Lower Palaeozoic rocks of Wales and the Welsh border country, and on the zonal study of the Carboniferous Limestone, in papers published mainly by the Geological Society of London.

Important proposals for the reclassification of the Lower Palaeozoic have been made by E. O. Ulrich of the U. S. Geological Survey, in a paper which, owing to the extreme changes proposed, has been issued in the Bulletin of the Geological Society of America (23, 1912, pp. 261–680) with a note by the Director of the Survey disclaiming responsibility for its views. Ulrich classifies the Lower Palaeozoic into five systems instead of three, adding the Ozarkian and the Canadian systems between the Cambrian and Ordovician. Neither system is likely to be welcomed by British geologists, for there is little evidence for them in the British Isles. The Ozarkian system is either absent or is represented only by the Upper Lingula Flags; the Canadian system includes the British Tremadoc and Arenig Series. The proposed systems have not been widely accepted in America. The better American representation of this part of the geological record has enabled Dr. Grabau to settle an old problem in the northwest of Scotland; he confirms Salter's view that the Durness Limestone is Ordovician, and not Lower Cambrian, to which it was transferred from its superposition on the Lower Cambrian quartzites with *Olenellus*.

Much light has been thrown on some stratigraphical problems by the separation and identification of the heavy constituents of rocks—a method especially advanced by the work of Boswell. The Kainozoic classification of many areas has been put on a firmer basis by detailed palaeontological work, which has permitted the correlation of different sequences of beds in independent basins, as in California (for example, by B. L. Clark, 1921), and in Australia and New Zealand, largely by F. C. Chapman. Man has been traced back into the Pliocene by the rostrocarinate implements found in the Red Crag by Moir (*see* Archaeology), which, however, like the early Palaeolithic implements from the Forest Bed of Cromer, are not universally accepted. A great stimulus to the study of the geological history of man followed the description of the Piltdown skull (Eoanthropus) by Sir A. S. Woodward (*Quar. Jour. Geol. Soc.*, 69, 1913), and important skulls have been found in Queensland, South Africa and Palestine (*see* Man, Evolution of). Claims have again been made for the occurrence of early man in America, but without carrying conviction. The reports published by various Antarctic expeditions have thrown much light on glacial processes, strengthening doubt as to the extent to which ice erodes hard rocks, attaching increased importance to the shattering action of frost, and supporting the subaqueous origin of boulder clay from its absence on the Antarctic lands and its formation on the floor of the Ross Sea. (*See* Palaeontology.)

Palaeogeography

The steady advance of stratigraphical geology enables palaeogeography to be placed on a firmer footing and its data have been summarised in a series of works by Theodor Arldt, *Handbuch der Palaeogeographie* (1919). Eduard Suess's great work, *Das Antlitz der Erde* was completed in 1909, but the comprehension of his views has been much aided by the French translation edited by Prof. E. de Margerie (completed 1918), with its invaluable collection of maps and supplementary material. Suess's teaching has led to increased recognition of the fundamentally different arrangement of ocean and continent in former times, combined with the stability of some areas and the weakness of others. E. Haug in his *Traité* (completed 1911) has laid stress on the importance of the geosynclinals as mobile bands. C. Schuchert (1923) in several luminous contributions to the palaeogeography of North America has also shown the continuous influence of the geosynclinals and has organised symposia which have collected on various problems expert opinion which might otherwise not have been expressed.

Ruedemann (1923) believes that in spite of the many changes in the earth's geography three archi-continents have persisted throughout geological time. This view has, however, been criticised by W. J. Miller, who considers that it is impossible to distinguish between the pre- and post-Cambrian folding.

L. Kober has extended his theory of the Alpine structure to the world in general; he explains the distribution of land and water as due to the massive resistant coigns having been surrounded by weak belts, which sink in geosynclinals, are then crumpled into fold mountains, and on refoundering may carry down with them adjacent parts of the continental blocks.

Climatic Changes.—In connection with stratigraphy a good deal of attention has been devoted to former variations in climate (*see* Climate), which many authorities refer to changes in the heat emitted from the sun, leading at times to universal refrigeration. This view has been strongly advocated by Huntington and Visher (*Climatic Changes*, 1922) and some change of this nature is regarded as probable by Jeffreys. Prof. Coleman (*Amer. Jour. Sci.*, 1924, pp. 298–404) has called attention to the world-wide nature of the refrigeration during the Pleistocene glaciation. The leading alternative explanation rests on geographical changes in the arrangement of ocean and continent or in the relief of the land. Prof. William Ramsay of Helsingfors (*Geol. Mag.*, 1924) points out that a period of high relief produces a cold climate and that the wearing down of the land into extensive peneplains produces a milder climate. C. E. P. Brooks, *Evolution of Clim* (1922), gives important help to this line of explanation by c culating the quantitative effects of changes in the position land and water. Of the former glacial periods, the known ran of that in the Upper Carboniferous and Permian has been grea extended, especially in America, in Brazil, Paraguay and t Argentine, and in the eastern United States, where Quayle h shown that the till at Squantum near Boston is a boulder clay this period. There has been a tendency to attribute all coa boulder beds to glacial action, though some have now receiv other explanations. The glaciation in South Australia a Central China is generally regarded as belonging to the upp part of the pre-Palaeozoic instead of Cambrian.

Darwin's theory of coral reefs has gained general acceptan and the main interest in connection with them has been fr Daly's view that their up-growth was due to the rise of sea-le owing to the release of water by the melting of the glacial i sheets. This argument is largely based on many of the co reefs rising from banks at the depth of 100 fathoms; but th banks and platforms are probably cut down to that level, as is the lower limit of wave action. The numerous variations level of raised coral reefs and beaches do not support a unifo world-wide rise of the oceans. The irregularity in the rise a fall of coral reefs has been explained by Molengraaff as due the isostatic subsidence of volcanic areas by the weight of t volcanic materials being favourable to the growth of coral ree

Economic Geology

Perhaps the most marked change since 1910 has been the i proved status of economic geology, due to recognition of its i creasing practical service, and to the value of its contributions academic science. The further study of coals has strengthen the view that anthracite is formed from the same vegetation bituminous coal, the difference being due to subsequent change The enormous increase of output of oil, which has been mag fied more than threefold in the past 14 years, has roused anxiet as to the duration of the supplies. Oil geology attaches less valu than formerly to anticlinal structure as indispensable to a pro itable oil field. Oil prospecting has revealed the form a structure of the salt domes, and the oil fields in Persia have b come the most important under British control.

The extensive boring stimulated by the high prices of 1916– led to energetic well drilling from 1917–22, and to a sensationa increase in oil production in California. It is doubtful whethe the oil output can be extended to meet the growing deman or even be maintained, although improved methods of extracti of oil from beds will lengthen the life of many fields. The ind cations of a decline in some of the leading sources of supply hav led to increased attention being paid to oil shale, in the expectation that before the end of the century it will be the main sourc of mineral oil. Discussion on ores of magmatic origin indicate that they are relatively unimportant, unless the term be s defined that practically all primary ore deposits are regarded a magmatic. There has also been increasing recognition of th importance of magmatic water—as in the series of papers by American authors (*J. G.*, 32, 1921, pp. 177–225, 292–310, 373– 449–71), who agree that part of the water from the hot spring of the United States is of deep-seated origin.

The deep flowing wells of east-central Australia have con tinued to decrease in volume, supporting the view that the flow is due partly to the plutonic water which rises from bel and mixes with the water stored in the stratified beds. No sing chemical distinction has been found by which the proportion the plutonic to the meteoric waters in a deep-seated supply ca be determined; but, with the prolonged age now accepted for th world, a small annual supply of plutonic water would, in th course of geological time, make an important addition to th volume of the oceans.

(J. W. G.)

GEOLOGY: NEW THEORIES (*see* 11.638).—In considering the gin of continents and oceans it is important to have a clear a of the magnitudes concerned. If we imagine a globe a foot diameter to represent the earth, with all its features in their ie proportions, by far the greater part of the ocean will be less an $\frac{1}{200}$ in. deep and only its extreme depths will reach $\frac{1}{100}$ h. Almost the whole of the land will rise less than $\frac{1}{1000}$ in. ove the sea and even Mt. Everest will have an altitude of s than $\frac{1}{100}$ inch.

Leaving out of consideration exceptional heights and depths e difference in level between the surface of the land and the or of the deep oceans will be less than $\frac{1}{200}$ inch. These are e features for which we are trying to account. Of the 12-in. be all that lies more than an inch beneath the surface is der conditions of temperature and pressure which cannot be proached in our laboratories, and we have no experimental owledge of the behaviour of materials under such conditions. oreover, time is an important factor, and our experiments give t little indication of what may happen under stresses acting thousands or millions of years. It is not surprising that there no general agreement as to the causes that have produced the esent distribution of land and sea.

Earlier Ideas.—Throughout the greater part of the last century geologists in general believed that our present continents d oceans were only temporary features of the globe. It was sy to prove that much of the land had once been beneath the a, it was not possible to show that any part had always been nd. It was reasonable to suppose that much of the ocean had ce been land, it was not unreasonable to imagine that no part d always been sea. In the last quarter of the 19th century, wever, the idea of the permanence of the ocean basins began gain ground. It cannot be said that there is any universal reement upon the question even yet. Many geologists are w inclined to ascribe a high antiquity to the Pacific Ocean it to look upon the Atlantic and Indian oceans as comparavely modern. Haug and others still suspect the former existce of a Pacific continent.

If continents and oceans are not permanent the present stribution of land and sea is only an episode in the history of e globe and has no more significance than the distributions in e past. It was not geologists therefore who first endeavoured formulate general theories to account for the present shapes continents and oceans. Those who made such attempts nored the changes in the past and their speculations were ceived with little favour by geologists.

The Tetrahedral Theory.—By far the most suggestive of these eculations was the tetrahedral theory of Lowthian Green. It as to some extent foreshadowed by him in *The Edinburgh New hilosophical Journal* in 1857 and was fully elaborated in his *estiges of the Molten Globe* in 1875. Following the widely accepted notions of the time, he assumed that the earth is cooling, ie interior contracting more rapidly than the exterior, and nder the force of gravity the outer crust collapses. Fairbairn's periments on the crushing of wrought-iron tubes led him to beeve that the collapsing sphere will tend to approach a tetraheral form. The corners of the tetrahedron will rise above the ater, forming triangular masses of land; the faces of the tetraedron will remain covered and will form the oceans. He places ie of the corners at the South Pole and the other three in the orthern Hemisphere. The corner at the South Pole is the ntarctic Continent and the opposite face of the tetrahedron is vered by the Arctic Ocean. The triangular masses of land rmed by the other three corners are represented respectively y North and South America, Europe and Africa, Asia and ustralia, all of them wide toward the north and tapering toward ie south. The two last are united in the north, but the Caspian epression is below sea-level and the plain of the Obi but little ove it. Between these three land-masses lie the Atlantic, dian and Pacific oceans, all narrowing toward the north and, the south, where the tetrahedral edges are lowest, uniting to a continuous belt around the globe.

The actual form which Lowthian Green believes the earth to have reached is the hexakis-tetrahedron (*see* 7.575, fig. 29), and he supposes that all the faces are much rounded so that the departure from the spheroidal form is only slight. Lowthian Green's theory was entirely neglected in England for many years, but was more favourably received in France. De Lapparent seems to have been the first to recognise it as a probable hypothesis and at a later date both Michel Lévy and Marcel Bertrand adopted it in a modified form. Since the closing years of the last century a tetrahedral theory in some shape or other has been accepted by many writers in England, Germany and America.

Modifications of the Tetrahedral Theory.—That the lithosphere shows some approximation to the tetrahedral form is matter of observation and not of theory. But that the approximation is only rough is indicated by the fact that the writers who support the theory do not all place the tetrahedron in the same position. Michel Lévy's tetrahedron, for example, is not the same as Lowthian Green's. The question naturally arises whether so ill-defined an approach to the form is due to some general cause such as Lowthian Green imagined, or to the accidental concourse of a number of minor causes. If the form is due to a general cause, then, since three of the corners of the tetrahedron are placed symmetrically with respect to the axis of the earth, the three land-masses which represent them should have a similar geological history. In particular it might be expected that their coasts should show some uniformity of type. But, as has been pointed out by Suess, the Pacific and Atlantic coasts differ fundamentally in character. The former runs parallel to the folds that have affected the surrounding land, and it is clear that the cause that produced the folds also determined the coast. The Atlantic coast, on the other hand, in general cuts right across the folds that have affected the neighbouring land and must owe its origin to another cause. The difference is too great to be accounted for by later modifications of coasts which were originally of similar origin. Further, if the differences are due to later modifications, the approximation to the tetrahedron should have been closer in the past than it is now. All the available evidence goes to show that the tetrahedron which fits best to the present distribution of land and sea will not fit at all to the distributions in past times.

On physical grounds objection has been raised that the tetrahedron is not a figure of equilibrium for a rotating earth, and even a slight approximation to it cannot be retained. Gregory has suggested that there may have been periods of collapse with an approach to the tetrahedral form, and in the intervening periods the spheroidal form was resumed. Moreover, in these periods of collapse the tetrahedron may not always have been in the same position, and thus we get the different distributions of land and sea in the past. Other writers also place the tetrahedron differently for different periods, but the geological evidence in favour of these views is not convincing.

Suess's Theories.—A great advance in our knowledge of the history of the globe was made by Suess in his *Das Antlitz der Erde.* He showed that there are large areas where even the oldest fossiliferous beds still lie horizontal. Here the crust of the earth has been rigid, in the ordinary sense of the term, since Cambrian times. It has broken, but it has never crumpled. Between these areas lie broad belts in which the strata are often folded. Here the crust has been weaker and has yielded to tangential pressures by crumpling and overthrusting. The crumpling was not a continuous process. There were well-defined periods of folding separated by intervals during which the whole earth was free, or almost free, from such disturbances. During these intervals, however, fracturing of the resistant areas took place and large blocks sank; and there were also wide extensions or " transgressions " of the sea over the land. Some of these transgressions seem to have been nearly simultaneous throughout the world and the whole land-surface must have been greatly reduced. The most extensive of them, so far as positive evidence can be adduced, occurred in the middle and later parts of the Cretaceous period.

In the Northern Hemisphere there are three areas in which the Cambrian beds remain unfolded. These are: (1) " Laurentia," which includes most of Canada east of the Rockies and probably stretched to the Western Is. of Scotland, (2) the "Baltic Shield" and "Russian Platform," (3) "Angaraland," which includes a great part, but not the whole, of Eastern Siberia. In all these areas, except upon the Russian Platform, no marine beds of Mesozoic age have been found, and during the Mesozoic era they were land. Probably by that time Laurentia and the Baltic Shield had been united by the folding of the intervening belt that took place at an earlier date.

In the Southern Hemisphere Cambrian fossils have only been found at one or two localities, but there are areas in which the oldest fossiliferous beds known show no folding. The most extensive of these is "Gondwana-land," which includes the greater part of South America east of the Andes, most of Africa between the Atlas and the mountains of the Cape, Arabia, Syria and the Peninsula of India. Strictly speaking, perhaps, the whole of this region should not be called Gondwana-land, for the Cretaceous sea extended far over it and even marine Jurassic beds are found in places. But much the larger part was land throughout the Mesozoic era. A similar remark applies to a great part of Australia. Between the Mesozoic land-areas of the north and those of the south lies a belt in which the Mesozoic beds are for the most part marine. This is the "Tethys" of Suess.

Between the rigid masses of the north and those of the south the more yielding crust beneath the sea of Tethys was crushed, and the great series of mountain ranges which run from west to east across the Old World was elevated. Tethys was much reduced in size and is now represented chiefly by the Mediterranean Sea. About the same time Laurentia and Gondwana-land broke up, large portions sinking beneath the sea, and thus the present Atlantic came into existence.

Such are some of the more important events in the history of the globe according to the researches of Suess, and it is impossible here to enter into further detail or examine the evidence more closely. The Pacific appears to have been sea throughout the Mesozoic era at least, but nevertheless it has functioned as a rigid area.

Suess imagines that the interior of the earth is contracting and the crust settling down upon it. The settling is accomplished partly by the fracturing of the more rigid portions, partly by the crumpling of the more yielding parts between them. Sometimes one portion of the crust is pushed over another and thus there must have been changes in the relative positions of different points upon the surface, but in comparison with the size of the globe these changes are small.

The Wegener Hypothesis.—Wegener introduces an entirely different conception, according to which the relative positions even of whole continents have altered greatly in quite recent times. The idea is not altogether new, for Schwarz had already suggested that Africa and South America were once nearer to each other; and other writers, on less solid ground, have made somewhat similar suggestions. But Wegener goes further than his predecessors and brings forward a much greater body of evidence.

Sial, Sima and Nife.—It has long been known to geologists that the visible part of the earth's crust consists chiefly of the lighter and more acid rocks, and beneath this it has been commonly supposed that there lies a layer of the denser and more basic rocks. The interior core must be denser still. In formulating these ideas Suess proposed the names Sal, Sima and Nife for the three concentric regions respectively. The term Sal is now usually replaced by Sial, and with this modification Suess's nomenclature is widely adopted. It has generally been supposed that the sial covers the whole globe. It may be thinner under the oceans and thicker on the continents, but it is present everywhere. Wegener believes that the sial is discontinuous. The floor of the ocean is formed of sima and the continents are sheets of sial floating in the sima. Because the sial is of smaller density its surface rises above the surface of the sima. The sima is not liquid in the ordinary sense of the word; but there is no perfect solid, and the sheets of sial, supposed to be about 100 km. thick, could not lie upon the sima without the force of gravity pressing them in until they floated
like a cork in water. This is quite in accordance with the
servations of geodesists, which indicate that the earth is
nearly in a state of isostatic equilibrium.

It was long ago shown by Pratt that there must be an exc
of density beneath the oceans and a deficiency beneath
elevated regions; and Airy suggested that all elevated mas
must be supported by a downward protuberance of the ligh
rock of which they are formed, into a denser layer below—
fact by flotation. It should be noted, however, that all
observations are equally consistent with the notion of a c
tinuous sial thinner in oceanic areas and thicker in elevated
gions, the downward extension into the sima bearing such
relation to the protruding portion that the whole is in hyd
static equilibrium.

Wegener's view is that the sheets of sial are not only separ
and floating in the sima but also moving laterally, and that th
positions relatively to one another have altered in the past a
are altering still. There are certain forces arising from
rotation of the earth and the attraction of the moon which wo
tend to cause lateral movements. Whether they are sufficie
to produce such movement through so resistant a medium
the sima is open to question; but it is conceivable that th
may be.

Wegener says that if we take the edge of the continental sh
as the edge of the sial sheets and allow for the effects of Tertia
folding, the pieces of sial can be fitted together into one c
tinuous sheet covering about a third of the globe. This,
thinks, was the condition at the close of the Palaeozoic era.
brings Africa and South America together and both into cont
with the Antarctic continent. Australia also is placed agai
Antarctica, and Madagascar and the end of an elongated Ind
are wedged between Africa and Australia. In the north, Gree
land, Canada and north-western Europe come together but
wide gap is left between the rest of North America and t
continents of Europe and Africa.

Criticisms of the Theory.—There is far too much scope for t
imagination in this process. Wegener does not follow the edge
the continental shelf with any precision, and the allowance th
he makes for the Tertiary folding is purely fanciful. Moreov
in his fitting he has introduced great distortion. If we keep t
masses rigid and fit South America into the Gulf of Guine
Canada will not come within 1,000 m. of the position it occup
in his scheme. Indeed, if his theory rested solely on the eviden
of fitting, it might be dismissed at once. But there is mu
stronger evidence than this. He says that with his fitting t
geological structures on the eastern side of the Atlantic beco
the direct continuation of the structures on the western si
The argument is weakened by the great amount of distorti
that he has introduced to make them fit, it is almost entire
destroyed by the real facts. Several of his statements are qu
at variance with those of the actual observers, and others r
on a very imperfect basis.

It is in the Southern Hemisphere that the geological eviden
for a former union of the continental masses is strongest, and it
perhaps significant that the nearest approach to a fit is th
between Africa and South America. The close similarity betwe
the rocks and fossils of these two areas has led most geologis
to assume a former land connection. Both regions are cha
acterised by the occurrence of the fossil *Glossopteris* flora, whi
differs considerably from the contemporaneous flora of Europ
The same flora has also been found in India and Australia. A
these are brought together in Wegener's scheme and the si
ilarity in rocks and fossils is at once explained. But the arg
ment is considerably weakened by the fact that the *Glossopter*
flora is also found in Siberia and northern Russia, which in h
reconstruction become farther away from the presumed home
Glossopteris than they are at present. In view of our very i
perfect knowledge of the geology of Asia, and the discovery of th
Glossopteris flora in a few other Asiatic localities, it seems pro
able that it had a wide distribution and was far from confine
to the regions that Wegener brings together.

Associated with the *Glossopteris* beds in South America, Afric a and Australia there is a boulder bed containing glaciated ders, which has long been a puzzle to geologists. On the most urable supposition with regard to the position of the South the ice that carried the boulders must have extended nearly he tropics, and it seems improbable that any glacial period d have reached the required intensity. In Wegener's re- struction of the period all these areas come together and ld lie within a reasonable distance of a suitably placed pole. here again there are difficulties. A similar boulder bed, also ciated with beds containing a *Glossopteris* flora, has been d in Afghanistan, which, with Wegener's fitting, must have within thirty degrees of the equator when the other areas e centred about the pole. The Afghanistan boulder bed was down near sea-level, for it is associated with an alternation arine and terrestrial deposits.

general it may be said that Wegener's theory removes cer- difficulties, but in removing them it introduces others of al magnitude. By far the most suggestive point in his ur is the resemblance between the African and South erican rocks and fossils. Even here Coleman, who has ex- ned the South American boulder bed, states that the ice ch deposited it reached the sea on the eastern side of South erica.

oly and Radio-activity.—Joly's theory is based on the effects adio-activity. Like Wegener he thinks that the continents are ets of sial floating in the sima, which forms the floor of the an. Relative displacements of the continents may have taken ce, but only at certain periods.

he sial and the sima are both radio-active and the radio- ive elements in them are continually generating heat. Unless heat can escape the temperature must rise. The melting nt of the sial rocks is known to be much higher than that he sima, which is basaltic in composition.

uppose that at a certain period the whole of the sial is solid the sima also is solid down to a considerable depth. Heat can y escape by the slow process of conduction. Beneath the sial re will be no escape from the sima, because the base of the sial lf, owing to its own radio-activity, must be nearly at the lting point of sima.

ince the escape of heat is so slow the temperature rises and sima melts to within some 20 m. of the surface. Tidal movements in the molten sima acting upon the downward projections the sial move the whole crust so that the local accumulations heat originally formed beneath the sial come to lie under the n layer of solid sima beneath the ocean. This is quickly nned still further, and molten sima escapes through fractures. e loss of heat now becomes more rapid and an era of cooling d consolidation begins..

We must suppose, then, that there are periods during which the a layer melts more or less completely and periods during which olidifies down to a considerable depth. It has been shown ex- imentally that basalt, and most other rocks that have been ed, expand on melting and decrease in density. As the sima lts it expands, and therefore the general level of the earth's face is raised. But because the density of the sima is de- ased the masses of sial which are floating in it sink more ply into the layer. Their surfaces, owing to the general rise, ome farther from the earth's centre, but, relatively to the face of the sima they are depressed. In this way the wide- ead transgressions characteristic of certain geological periods explained. As the sima cools again and becomes denser the face falls, but the sial masses rise relatively to the sima.

When the sima begins to cool, the crust upon it, if not already mplete, is soon completed by the consolidation of molten ma- ial in its fissures. Together with the sial masses it now covers whole globe. But the sima continues to contract further, and covering becomes too large. And now begins a period of ding and other earth movements to enable the crust to descend th the sima.

It is not possible here to enter further into the consequences of theory. Its great merit, from the geological point of view is at it seems to offer a clear explanation of the most remarkable features in the history of the globe, the periodicity of earth-folding and sea-transgressions and their widespread character.

Conclusion.—In view of our ignorance of what goes on in by far the greater part of the interior of the globe it remains improbable that any theory founded on examination of a thin external skin can be wholly true. The old hypothesis of a contracting core fits the observed facts of geology as well as any other. It has been urged that the possible amount of contraction is insufficient, but on this point it is unsafe to dogmatise. Recent astronomical observations show that the companion star of Sirius consists of gas and yet is denser than any material upon the earth's surface. A discovery so unexpected leads us to revise our ideas and, though the conditions are very different, renews interest in the suggestion of Arrhenius that the interior of the earth is gaseous.

Wegener, *Die Entstehung der Kontinente und Ozeane* (1920)—an English translation appeared in 1924; J. Joly, "The Movement of the Earth's Surface Crust," *Phil. Mag.* (1923), also *Radio-activity and the Surface History of the Earth*, Halley Lecture (1924) and *The Surface History of the Earth* (Oxford, 1925); H. Jeffreys, *The Earth* (1924) is of special interest from the point of view of geophysics in general and lends support to the contraction hypothesis.

(P. LA.)

GEOMETRY (*see* 11.675).—The usual history of the development of the ideas of a student of geometry in England to-day is somewhat as follows: After a more or less prolonged (and highly desirable) course of experimental geometry, very largely (and undesirably) limited to a plane, in which a line is a mark made on paper, and a straight line is a mark which agrees with a physical object (a ruler), the student passes through a course in which he is shown that there is a logical connection between the geometrical conceptions his experience may have led him to form.

I. FOUNDATIONS

At first, and for a long time, often permanently, lines and circles are regarded as objects of perception and, for instance, there is no hesitation in accepting the idea of two lines being in the same direction, and it appears intuitive that two points must have a certain distance, a result of familiarity with the rigid bodies which the student has had put before him. This teaching, after a certain knowledge has been obtained of the detailed relations of circles and lines, often painfully acquired and difficult to remember, is continued on the same plan, for the so-called geometrical properties of conic sections, though these are apt to appear at first as much less concrete than circles.

After this, as soon as some facility with algebraical computation is acquired, the student learns that a straight line has an *equation*, and that, *e.g.*, the common points of two circles depend on the solution of a quadratic equation, while the common points of two conics depend on a quartic equation. If his instruction is pursued far enough, he learns, with the expenditure of much time and energy, a vast number of algebraical devices, and is now, if apt in using them, capable of proving algebraically almost any question that his usual examinations are likely to require of him.

For his further efficiency to this end he is probably taught towards the close of his career something about harmonic relations, about homography, and about projections. In particular, for example, he may be taught that the equations which give the foci of a conic are obtainable by applying the analytical conditions for a circle to the equation of the pair of tangents to the conic from any point. If he is fortunate it may be pointed out to him, near the end of his laborious drilling in detail, that a circle behaves as if it were a conic with two definite (albeit imaginary) points; and if he must in any case know the properties of conics he may, for economy of memory, seize hold of this remark, and come also to a geometrical description of the property of foci just referred to—and pursuing this course, if circumstances allow, he may finally reach a framework of hypothetical constructions including the so-called circular points and the circle at infinity, from which, looking back, as from a hill-top, he sees the whole country of geometrical fact, with which he has so laboriously become acquainted, shrink into a landscape dominated by very few main routes.

He may now be at the stage of the third year university student. With continued consideration he may be led finally, even if only with the purpose of summarising his geometrical outlook in the fewest possible ideas, to regard as working hypotheses such as the following: (*a*) there is no fundamental difference between points at infinity and those not at infinity; (*b*) there is no difference in reality between real and imaginary points; (*c*) there is no gain but great loss in refusing to consider space of more than three dimensions; (*d*) distance, as a fundamental conception is unnecessary. And with these will come a recognition that the so-called non-Euclidean geometries are logically prior to the Euclidean geometry.

Leaving aside now the tempting pedagogic question of whether he has been justly treated in being so long denied the synthesis which, if he could have appreciated it, would so much have lightened his task of becoming familiar with the details, we remark that he finally works with a conceptual scheme which includes the perceptual experiences by which it has been suggested —but discards many ideas which at earlier stages his perceptions seemed to suggest as necessary. For instance, the points of a line are not now in (linear) order, and lines have lost their straightness, the lines of threefold space being for many purposes better regarded as points of a quadric in five dimensions.

Questions then arise such as: is geometry unique in thus replacing the first crude ideas of physical experience by a conceptual scheme of entities, whose properties are determined logically, not from a set of *definitions* which tell us what these entities are, but from a set of fundamental propositions or statements of relations between them? And connected therewith: are the ideal entities of such a conceptual scheme less *real* than those, for example, which the physicist employs, say the aether or electrons, to explain his conceptions? May the statement that distance is not necessary as a fundamental conception be fairly replaced by the statement that distance in the abstract is an illusion? It would seem that the difference is one only of the degree of abstractness of the conceptual scheme employed. We may in geometry itself have different levels of abstractness; for example, we may in the first instance regard the points of a line as conforming to our idea of an abstract order of such a kind that the so-called Dedekind's axiom is applicable, although finally when we allow the so-called imaginary points we discard this notion of order and use the word line in a still more abstract sense. It would seem that every science as it advances in comprehensiveness must similarly evolve for itself a conceptual scheme of ideal entities; and that in strict logic, no proposition can be asserted to be true or false except in reference to entities whose fundamental relations have been made explicit.

Such questions as these arise when it is assumed that it ought to be possible to ascertain by observation whether the world is finite, or still more whether space (in the abstract) is Euclidean or non-Euclidean. If the attitude which has been suggested is sound, the most that can be done is to inquire what would be the modifications in our statements of perceptual regularity which would follow if we adopted a particular scheme of conceptions in regard to the extent of the world, or the character of space.

Of such conceptions, those which have reference to a method of measurement are of fundamental importance. And if measurement is possible at all, it must presumably be based upon a scheme for assigning identification numbers to the points of bodies which are to be measured. This is not the same as assigning numbers to points of space, nor, even if this could be done, would the method of measurement be determined uniquely thereby. A way of assigning identification numbers to the points of a figure must be conditioned (*a*) by the fundamental theorems of incidence of the elements of the figure (as that a line is determined by two points, or that two planes meet in a line); (*b*) by the nature of the numbers to be used (whether they allow commutative multiplication, for example); (*c*) by the freedom of the assignment, that is the number of points of the figure for which the corresponding numbers may be assigned arbitrarily, the numbers belonging to any other point being then determinate; (*d*) which is in fact included under (*a*), by the character of
the "infinity" of the figure (as whether the space of the figu
open or closed); and even then (*e*) it appears to be necessary
assume one or more definite limiting theorems of incidence.

In the way which has been studied most in detail, as being
which is most naturally suggested by the Euclidean scheme in w
geometrical thought has developed, the numbers being taken t
those of ordinary arithmetic, it is possible to assume arbitrarily
numbers for three points of a line, so long as this is considered
itself, the numbers of four points of a plane regarded as isolated,
the numbers of five points of a three-dimensional space; this spa
regarded as closed, the numbers belonging to a point are regar
as ratios of numbers, and infinite values of numbers are thereby
cluded from consideration—and the assumption is made that
lines of which no two intersect have two common transversals.
is shown that the introduction of this assumption is equivalent (ot
things being equal) to assuming that the numbers used are commu
tive in multiplication. The number space of Descartes, in which e
point is represented by three ordinary numbers, one or more of wh
may be infinite, may be regarded as a particular case of the so-ca
projective space thus described.

In his famous *Habilitationsschrift* (1854), when 28 years old,
Riemann considered a Cartesian space in which each point is speci
not by three but by n numbers or co-ordinates, and proposed
measure the distance between two neighbouring points by means
a quadratic function of the small differences of their correspond
co-ordinates. He remarked then that such a space has not nec
sarily any rigid bodies capable of movement without change
linear dimensions. For this to be possible it is necessary and su
cient that certain functions of the co-efficients in the quadra
form and their differential coefficients should be constant. T
number of these functions is $n^2(n^2-1)/12$; for instance, for $n=$
this number is 1, and for $n=3$, it is 6. When these conditions
satisfied the space is said to be of constant curvature. But it is
be remarked that a Cartesian space of n dimensions, such as th
considered by Riemann, is in reversible, point-to-point correspo
ence with a quadratic manifold (also of n dimensions), in a p
jective space of $n+1$ dimensions. In such a space of $n+1$ dimensio
as was first remarked by Cayley, we can set up a measurement
distance between any two points by taking, quite arbitrarily,
quadric manifold of reference. It is then the case that Rieman
definition of distance, when his space is of constant curvature a
allows rigid bodies capable of movement, is so obtainable af
Cayley's manner.

These details appear to bring out very clearly that even when t
difficult step has been made of passing from the descriptive pro
erties of a geometrical figure to the assignment of co-ordinates,
is a further step of much artificiality to introduce a measure of t
distance between any two points.

In recent years, under the stimulus of A. Einstein, H. Mi
kowski, H. Weyl and others, Riemann's dearest dream of a u
form formulation of all phenomena of physics, has, it would see
been brought appreciably nearer to realisation, in what is know
as a Theory of Relativity. An event, occurring in a defini
place at a definite time, is regarded as depending on three co-or
nates for its position, and one for its time, and these four togeth
are spoken of as its co-ordinates in a Cartesian space of fo
dimensions. As formulated by Einstein, there is an interv
between two neighbouring events, given by a quadratic in th
differences of their corresponding co-ordinates; this quadratic wi
then have 10 co-efficients. (*See* RELATIVITY; SPACE-TIME.)

It can be shown that there exist functions of these coefficients an
of their derivatives in regard to the point co-ordinates, which are u
changed in value if calculated for the quadratic form into which th
given one is transformed by any transformation of the co-ordinates
for instance, the 20 functions which, as has been stated, arise in th
consideration of what is called the curvature, are such functions
It is clear that the vanishing of such an invariantive function ex
presses a fact which is not altered by any simplification that may b
possible in the form of the quadratic expression. For instance, if th
20 functions above referred to all vanish, the quadratic expressio
has a form the same as in Cartesian Euclidean geometry; and
they are all equal to the same quantity independent of co-ordinates
the quadratic expression has the form considered by Riemann.

In Riemann's theory, following Gauss, account is taken of curves
called geodesics, which satisfy the condition that the integral $\int d$
taken along such a curve, shall be stationary according to th
ordinary rules of Lagrange's *Calculus of Variations*, where ds is th
square root of the quadratic expression referred to. Einstein's sug
gestion is that the path of a particle under the influence of what w
call gravitating masses may be represented as such a geodesic, pro
vided the coefficients in the quadratic form are chosen to depend
suitably upon these masses; and this has proved capable of verifica
tion in the case of the planet Mercury, and in the case of a ray o
light passing near to the sun.

An analogous suggestion has led Weyl not only to the equations
belonging to the theory of gravitation, but also to those which

ess the phenomena of electromagnetism (and light). And it is interesting from our present point of view to see the character e modifications which Weyl has been led to make in Einstein's ematical formulation in order to attain this end. For our ent purpose we may state this in a twofold manner without ring into the logical connections. In the first place, in Weyl's ry, instead of the quadratic form ds^2 being regarded as definite wo specified neighbouring events, a product ϕds^2 is regarded as ite, where ϕ is a function variable from point to point, whose vatives in regard to the co-ordinates are utilized to represent romagnetic phenomena.

s Weyl writes (*Math. Zeitschrift*, ii., p. 397, 1918), "Riemann hte die . . . Annahme, dass sich Linienelemente nicht nur an elben Stelle, sondern auch an zwei endlich entfernten Stellen Länge nach miteinander vergleichen lassen. Die Möglichkeit r solchen ferngeometrischen Vergleichung kann aber . . . nicht standen werden." This is precisely in the spirit which has ed geometers increasingly since the publication of G. K. C. von dt's *Geometrie der Lage* (1847). It introduces however evidently de arbitrariness which Weyl limits by adopting as a datum the ibility of the translation of a vector given at one point to her neighbouring point *without change of direction.* This conception adopted from T. Levi-Cività (see Levi-Cività, *Palermo, Rendi-i*, xlii., 1917, pp. 173–205, and F. Severi, *ibid.*, p. 254), is as ws: The two elements of direction defined by (*a*) the vector he first point P and (*b*) the displacement from P to the neighing point P′, define a family of geodesic directions through P, ing a surface; the parallel vector at P′ is that whose direction *his surface* makes with the direction PP′ the same angle as that le by the vector at P. Evidently the assumption of the possibility his determination of unchanged direction is fraught with large sequences or conditions. A suggestion subsequent to Weyl's S. Eddington, *Proc. Roy. Soc.*, xcix., 1921, pp. 104–122), ns with Levi-Cività's differential equations for parallel displace-t of a vector, but working backwards towards the quadratic rential form leads to a generalisation of Weyl's formulation.

o much of detail in regard to these remarkable contemporary culations seems necessary in order to compare the geometrical ects with those of older conceptions. In the so-called space of stein, still less in Weyl's space, there exist neither bodies, nor vement; and what are the fundamental geometrical condi-s assumed prior to the establishment of the system of co-inates is as yet undetermined. The latter fact, which is ally true of any Cartesian space, may provisionally be evaded regarding the space as being in point to point correspondence h a quadric manifold in a projective space of five dimensions; former fact, which relates to the consideration of a quadratic erential expression, is most probably, if it proves finally to be sible to put the phenomena of physics into exact correspon-ce with geometrical considerations, suggestive of a physical ory which, given some fundamental relations of experience, ll be developed not by computation, but by descriptive hods. For the aim of geometry, towards which since Von udt's time, much progress has been made, is such a descrip-e conception of the relations of figures in space as may render nputation unnecessary.

II. GENERAL THEORY OF SURFACES

he older theory of circles and conics, or of rational curves in eral, as also the theory of quadric surfaces, of cubic surfaces f rational surfaces in general, can be placed in (1, 1) correspon-ce with the geometry of lines, or of planes, respectively; it ls ultimately with linear equations when viewed analytically. onsideration of cubic curves on a plane, or of the curve of rsection of two quadric surfaces, soon shows that these do depend upon linear equations ultimately—or more precisely t the points of a plane cubic curve cannot be put into (1, 1) respondence with the points of a line. And it further ap-rs that a quartic curve in a plane is again of a higher category, cannot be put into (1, 1) correspondence with a cubic curve. his fact first emerges clearly in Abel's great paper on the inte-ls of algebraic functions. The general theory of the so-called her Curves was then historically subsequent to the theory of ebraic functions and the integrals of these; though, when theory had received a sufficient development, it proved pos-e to elaborate a descriptive theory of these curves embodying results obtained by the earlier analytical methods. In geom-y, entities which can be put into exact (1, 1) correspondence equivalent for geometrical purposes, and conversely, for purposes of a general theory, it is vital to know whether two entities have this equivalence or not. It is one of the most important recent developments of geometry to have made it clear that criteria can be given by which to determine whether two surfaces have this (1, 1) correspondence.

And it is interesting to remark that historically the development in this case has been on similar lines to that by which the corresponding result was obtained for curves; in the first place, over many years, Picard developed the theory of algebraic integrals associated with surfaces on lines as far as possible analogous to those which had been followed in the case of curves, therein in part carrying out a suggestion due to Klebsch and Noether, though the integrals which have proved most effective hitherto were not those suggested by Klebsch; after this the geometrical aspect of the matter was investigated by Italian geometers, more especially Enriques, Castelnuovo and Severi, who have succeeded in surpassing in beauty and generality even the distinguished contributions of their own countrymen to the theory of curves. It is impossible indeed to convey to a non-geometrical reader any idea of the interval which separates the development of geometry in Italy to-day from the development reached in England.

The new theory is under the disadvantage that an appreciation of it is impossible without sympathy and acquaintance with the theory of algebraic functions and their integrals, and it may be some time before detailed applications of it become the common property of mathematicians. But it offers a limitless scope for new work, its importance cannot be doubted and its permanence is assured.

Bibliography.—For the question suggested by the Einstein-Minkowski work, ample material arises in attempting to sift into logical coherence many of the current writings on Relativity. An ample bibliography of these concludes the work of Hermann Weyl, *Raum-Zeit-Materie*, Vierte erweiterte Auflage (Berlin, 1921). The English reader will find much stimulus to geometrical consideration in Eddington's volumes, *Space, Time and Gravitation* (Cambridge, 1920) and *The Mathematical Theory of Relativity* (2nd ed., Cambridge, 1924); and should consult E. Cunningham's two fundamental volumes on *Relativity*, and A. A. Robb, *A Theory of Time and Space* (Cambridge, 1914). Emile Picard's work is summarised in his book, *Théorie des fonctions algébriques de deux variables indépendentes* (Paris, 1897–1906), which concludes with a summary by MM. Castelnuovo and Enriques (t.ii., pp. 485–522) of the results obtained by the Italian geometers up to 1906. The reader may also consult the article by Severi in vol. II of Pascal's *Repertorium of Higher Mathematics* (German Edition, pp. 741–782, 1922). Subsequent progress is recorded (and scattered) in the various mathematical journals, mainly of Italy. (H. F. Ba.)

GEORGE V. (1865–), King of Great Britain and Ireland (*see* 11.745), succeeded to the British throne on the death of his father, King Edward VII., May 6 1910. By the Regency Act, 1910 (a temporary constitutional necessity in view of the fact that King George's eldest son, Prince Edward, was then not 16) his consort Queen Mary was at once nominated regent in the event of a demise of the Crown while the heir to the throne was under age. A new civil list fixed at £470,000 a year, was approved by Parliament in 1910. An important change in the King's accession declaration was also embodied in an Act of that year, the following short and simple formula being substituted for the old manifesto:—

> I do solemnly and sincerely in the presence of God profess, testify and declare, that I am a faithful Protestant, and that I will, according to the true intent of the enactments which secure the Protestant succession to the Throne of my Realm, uphold and maintain the said enactments to the best of my power according to law.

The coronation at Westminster Abbey, on June 22 1911, was attended by representatives from all parts of the Empire and other countries and, in order to complete the public assumption of royal authority throughout the United Kingdom, the King and Queen, with the Prince of Wales and Princess Mary made state visits to Ireland, Wales and Scotland during July. Later in the year Their Majesties visited India, and coronation ceremonies took place at the ancient capital of Delhi (Dec. 12 1911).

From the very first King George and Queen Mary showed in all their actions their earnest desire to use their royal position in the most public spirited manner. Great Britain was fortunate in the fact that so much had already been done, by Queen Victoria and King Edward VII., to establish the Throne in the hearts of the people as a central and unifying national and Imperial force, distinct from sectional interests of party or class. Under King George this tradition was steadily maintained. He and Queen Mary devoted themselves to the task of making the influence of the court a pure, useful and kindly one in the life of the country; they mingled with different classes of society and were ever active in accepting new opportunities of service. The personal tastes of both were known to lie in characteristically domestic directions. The royal stamp collection is the most complete in existence, and in 1920 the King assured the Junior Philatelic Society of his "unabated interest in stamp-collecting."

The War Period.—The value of the influence of the Crown, as standing above and outside domestic party politics, was emphasised by the Buckingham Palace conference of 1914 on the Irish deadlock; and by the conduct during the World War of the King and Royal Family who in various ways strengthened their hold on the affections of the British people. From the opening of the World War in Aug. 1914 the King and Queen jointly and severally set themselves to make the royal influence an encouragement to every form of national activity in aid of the fighting forces. The King and Queen regularly went in state to prorogue and open Parliament in successive sessions and on frequent occasions during the War royal visits were paid to important factories and workshops at the munitions centres throughout Great Britain, as well as to shipbuilding yards, hospitals and other institutions engaged in war-work of one kind or another. The King's inspections of provincial industrial establishments included visits to Glasgow and the Clyde, Coventry and Birmingham, Leeds and Sheffield, Nottingham, Liverpool, Manchester, Barrow and Gretna, Newcastle-on-Tyne, Hull and Rosyth, Bristol, Bradford and Huddersfield. Moreover, periodical visits were made by him to the Grand Fleet. In 1917 Queen Mary accompanied the King to France. Finally, after the Armistice, the King made another visit to Paris and to the battle-fields, Nov. 27–Dec. 10 1918, and had an enthusiastic reception in the French capital (Nov. 28–30).

In other directions during the war period, the King's desire to set an example of patriotic self-abnegation was frequently apparent. The long record of royal attendances at notable ceremonies included such occasions as the funeral services at St. Paul's for Lord Roberts (Nov. 19 1914) and Lord Kitchener (June 13 1916); the commemoration service there on the entry of the United States into the War (April 20 1917); the Albert Hall commemoration of the first Seven Divisions (Dec. 15 1917); the thanksgiving at St. Paul's on Their Majesties' silver wedding (July 6 1918); the presentation to the King at Buckingham Palace by the special Japanese mission of the sword and badge of a Japanese field-marshal (Oct. 29 1918); and other events. On the occasion of Their Majesties' silver wedding, the King and Queen were received at the Guildhall (July 6 1918) and were presented with a cheque for £53,000, subscribed by the citizens of London, to be devoted to charities by Their Majesties' wish, together with a silver tankard once owned by Charles II.

On July 17 1917 it was announced that King George V. had abandoned all German titles for himself and his family. At the same time a proclamation was issued to the effect that henceforth the royal house of Great Britain and Ireland would be known, not as the house of Saxe-Coburg-Gotha, but as the house of Windsor. It had previously been announced (June 20 1917) that the King had decided that those princes of his family who were British subjects but bore German titles should relinquish those titles in favour of British names.

Post-War Incidents.—With the return of peace it was possible for the more normal activities of court life to be resumed, but in the long list of later royal functions some stand out as worthy of record for their special appeal to contemporary public interest. Immediately after the Armistice in 1918, the King and Queen on successive days made popular progresses through different sections of London, and received general ovations, in carriage drives through the city (Nov. 11), to a special thanksgivin St. Paul's (Nov. 12), through the East End (Nov. 13), the s (Nov. 14), the north (Nov. 15), the northwest (Nov. 18) an southwest (Nov. 22). On Dec. 27 a banquet was given in our of President Wilson at Buckingham Palace, where he Mrs. Wilson were staying with the King and Queen.

On June 21–2 1921 the King and Queen visited Belfast, w His Majesty inaugurated the new Parliament of Northern land. The King, in his speech on that occasion, made an ap to all Irishmen to pause and stretch out the hand of forbeara to forgive and forget and to make for the land they loved a era of peace, contentment and good-will. When, in the follo Dec., an agreement was at last reached with the Irish State, the King in his telegram of congratulation to Lloyd George, ventured to hope that his own speech at Bel might have contributed to bring it about.

On Feb. 28 1922 the King's only daughter, Princess Mary, married in Westminster Abbey to Viscount Lascelles (eldest son of the Earl of Harewood. The King and Queen a state visit to Belgium on May 8. Early in the following (Feb. 7) a son was born to Princess Mary and on April 26 Duke of York was married to Lady Elizabeth Bowes-L fourth daughter of the Earl of Strathmore and Kinghorne. days later the King inaugurated the new Stadium at Wemb Middlesex, constructed in connection with the projected Bri Empire Exhibition, by attending the final cup tie of the Eng Football Association. On May 5 the King and Queen pai state visit to the King and Queen of Italy, remaining in Ro for some days. They were received by the Pope at the Vati on May 9, and on May 12 the King visited Montecchio inspect the graves of British soldiers, who had fallen in Italy.

The outstanding event of 1924 was the opening by the K on April 23 of the British Empire Exhibition at Wembley. and the Queen made frequent subsequent visits to the Exhibiti both privately and accompanied by their royal guests, the K and Queen of Rumania and the King and Queen of Italy, made state visits to London during May. On Sunday, May an Empire Thanksgiving Service was held in the Stadium, c ducted by the Archbishop of Canterbury and attended by King and Queen. On July 19 the King and Queen visited Liv pool and were present at the dedication of the new Cathed On Aug. 21 a second son was born to Princess Mary. Nearer throne was the daughter born to the Duke and Duchess of Y on April 21 1926 and named Elizabeth Alexandra Mary. May 9 1925 the King and Queen opened the second year of Wembley exhibition. (H. Ch.; J. E. C.)

GEORGE I. (1845–1913), King of Greece (*see* 11.746).—In 19 King George promptly recognised Veniselos' rare ability a gave him his whole-hearted support, though the latter had lo denounced the royal policy of *laissez faire.* Internal polit played only a secondary part in King George's reign; the Pa hellenic idea had absorbed the thoughts and resources of t Greek people ever since the recognition of the independence Greece. The King consistently strove to restrain the patriot exuberance of his subjects on the one hand, while endeavourin on the other, to use his great personal influence and family co nections abroad in favour of the aspirations of the Greek peopl His policy was consistently pacific. Even in Oct. 1912, whe Greece was preparing to declare war against Turkey, King Geor made it clear to Veniselos that he only consented to the ventu because of his obedience to the constitutional principle. He wa about to celebrate his jubilee when he was assassinated by Greek named Schinas at Salonika on March 18 1913. He wa succeeded by his eldest son, Constantine I. *See* Capt. Walt Christmas, *King George of Greece* (1914).

GEORGE II. (1890–   ), ex-King of the Hellenes, eldest so of King Constantine, was born on July 20 1890 at Tatoi, the roya villa near Athens. On account of his supposed Germanoph tendencies during the World War, he was excluded from th succession by the Allies in favour of his younger brother, Ale ander, upon the deposition of his father by the ultimatum

e 11 1917. After his father's restoration to the throne in 1920,
narried on Feb. 27 1921, Princess Elizabeth, elder daughter of
g Ferdinand and Queen Marie of Rumania. Upon the second
osition of his father by the revolution of Gen. Plasteras, his
nger brother Alexander I. having died in 1920 he succeeded
he throne on Sept. 27 1922. After the unsuccessful counter-
olution of Oct. 1923, his position became more difficult, al-
igh there was no proof that he had been a party to that rising.
ublican feeling grew under the leadership of M. Papanasta-
and others, and, despite M. Veniselos' advice to await the
sion of the National Assembly, a number of military and na-
officers demanded the deposition of the Glücksburg dynasty.
Dec. 19 1923 the King and Queen left Greece. Next day,
niral Condouriotes, for the second time, became regent. On
rch 25 1924 the Assembly deposed the dynasty and forbade
members to reside in Greece; and the plebiscite of April 13
firmed the vote of the Assembly (*see* Greece).

EORGE, DAVID LLOYD (1863–   ), British statesman (*see*
32). The 1910 conference of British party leaders lasted from
e till November. It was a strange pause of calm in the midst
he stormy events of that period. It is not true to say that
conference was a failure. The conferring leaders, on the con-
y, nearly arrived at a very comprehensive and far-reaching
eme of agreement, affecting all the disputed issues—the House
ords, Home Rule, tariffs and conscription. But the six months
ecrecy ended in detaching the leaders from their followers.
haps the secrecy was overdone, because very few whispers
ne from behind the closed doors of the conference room to
pare the party followers for the agreements which required
e ratified by the parties before they could become valid. The
ilt was that when the party leaders on both sides emerged
n the conference room they found their followers quite unpre-
ed to grant the concessions required from them. While the
lers had passed into a mood of conciliation, the followers were
l living in an atmosphere of party warfare. On both sides the
posals put forward were regarded as surrenders.

Mr. Balfour (later Lord Balfour) and Mr. (later Sir) Austen
amberlain found themselves in peril of being isolated, and Mr.
yd George was immediately denounced as an opportunist.
ng party leaders themselves they were compelled to bow to
storm. Yet it is a fit reflection now that, but for the World
r, this conference presented to Great Britain at that moment
last solid alternative to the civil war which even then loomed
ad. It is also interesting to observe that most of the confer-
e proposals were adopted later, during the War or after. Mr.
yd George was among those who took a sanguine view of the
spects of the conference, and afterwards he always regretted
failure. He took a long view. He was ready to come to very
d settlements if they would save the country from civil strife.
and Mr. Balfour agreed in this attitude. But public opinion
s not ready for compromise. Party tides still ran too strong.

Schemes of Social Reform

National Insurance.—The political conflict was resumed. In
cember there took place the second of the two 1910 general
ctions. It was, in effect, a test election on the Parliament bill.
e Liberal Govt. had refused to go to the polls until they ob-
ned the promise of the King that, if they were successful, he
uld consent to employ his prerogative of peer-making in order
carry the Parliament bill. That promise was reluctantly given
King George V. Mr. Lloyd George was returned for Car-
rvon Boroughs for the seventh time with an enhanced majority
208). But a second national campaign within one year proved
much for his strength, and he was struck down by serious
roat trouble for some months. During this compulsory retire-
nt he prepared the National Insurance bill of 1911. This was
e first of a series of measures for improving the condition of
e British working class by the method of social insurance. The
a was first applied by Bismarck in Germany in 1893, and Mr.
oyd George had made a study of the German insurance sys-
n during a holiday visit to Central Europe in the autumn of
08. Old age pensions had been already passed into law before that visit; and thus it was that the British system of old age pensions originally took a non-contributory form.

Mr. Lloyd George's first general application of the contributory insurance principle was to sickness and invalidity, and the proposal produced a formidable social and political crisis in the autumn of 1911. Mr. Lloyd George was proposing a new habit to the British people, and at the first shock it was profoundly unpopular. All classes rose against it. There followed a succession of political revolts; and it seemed as if the combination of forces—of the Conservatives—of the Press and the public—opposed to the bill would be sufficient to swamp it. By-election after by-election was lost by the Liberal Government. The party managers were in favour of postponement; but Mr. Lloyd George held on. He eased the passage of the bill by a series of conferences with all the disturbed parties. Early in the year he won over the insurance societies. The trade unions were never definitely hostile. The doctors, after a series of protests and defiances, were finally appeased by a combination of firmness and concession. So at last, pushing the bill through the House of Commons with the aid of a strong closure time-table, Mr. Lloyd George achieved its third reading early in Dec. 1911. The House of Lords, tired of conflict with the House of Commons, allowed Mr. Lloyd George's insurance scheme to pass into law without serious amendment. This was followed by Mr. Lloyd George with an Unemployment Insurance bill which broke new ground. It was extended in subsequent years over the whole working class, and did much to carry the country through the dark years of unemployment which followed the World War.

The "Marconi" Affair.—In 1912 Mr. Lloyd George approached the reform of the English land system by way of a land committee, of which Sir Arthur Acland was the chairman. Two reports were published, one on the rural and the other on the urban side of the existing system; and Mr. Lloyd George had already announced his intention of bringing forward a series of bills in the House of Commons to carry out the proposals of his land committee. He sketched the main lines of his policy in a series of speeches throughout 1912 and 1913. But just as he approached this venture his way was barred by two events—one personal, and the other national. The first was known as the "Marconi Affair," which produced a grave crisis in Mr. Lloyd George's career. He had been persuaded by his friend Sir Rufus Isaacs (later Lord Reading) to take £1,000 worth of shares in the American branch of the great Marconi company at a moment when the British Post Office was discussing the terms of a contract with the British company. The two companies were separate, and there could in fairness be no accusation of anything beyond carelessness. But Mr. Lloyd George—at that moment Chancellor of the Exchequer—was too formidable a political figure to be let off lightly. The proceedings became the subject of an inquiry by a committee of the House of Commons, and he was gravely censured in the report of the chairman, Sir Albert Spicer, a prominent Liberal member of Parliament, although the majority of the committee acquitted him of serious blame. A majority of the House of Commons replied to the opposition attacks by a vote of confidence in Mr. Lloyd George. But for the moment his position was shaken.

The Curragh Revolt.—Already overshadowed by these events, the land proposals were now effectively blocked by the far greater crisis of Irish civil war. Mr. Lloyd George always took a mediating attitude in regard to the relations of Ulster and Southern Ireland, but he was now acutely involved in the coming passage of the Home Rule bill with its proposal of a single Irish Parliament under the Parliament Act. Ulster, organised by Sir Edward Carson (later Lord Carson), threatened an armed defiance of the Government. This defiance had now its first effect in the revolt of the officers at the Curragh against the orders issued for carrying out the prospective Home Rule policy. Faced with the possibility of a military revolt both at the Curragh and at Aldershot, Mr. Lloyd George took a very grave view of the situation and devoted all his energies to preserving civil peace. But at this moment, at the very heart of this Irish crisis, there came the vaster and more momentous challenge of the World War.

THE FIRST WAR YEARS

Mr. Lloyd George's Position.—Lord Grey of Fallodon in his memoir, *Twenty-Five Years, 1892–1916* (1925), gives a vivid account of the state of division that prevailed in the Liberal Cabinet in the fortnight before the outbreak of War. During that period the attitude of Mr. Lloyd George was deeply affected by his position as Chancellor of the Exchequer. On the Saturday before the declaration of war—Aug. 1 1914—the Governor of the Bank of England headed a deputation to 11, Downing Street, urging the policy of neutrality upon the Government. The same governor on Monday, Aug. 3, when the Germans invaded Belgium, telephoned to Downing street withdrawing the opposition of the City, and declaring that they were now in favour of war. This change of opinion in the City was highly dramatic, but it reflected the attitude of the Chancellor of the Exchequer. Mr. Lloyd George at first was not in favour of Great Britain being drawn into a contest between the two great warring groups of Europe unless some British interest or some British obligation were clearly involved. Accordingly during the previous week he did not take up the decisive attitude against Germany which he adopted in 1911, when he held the view that the claim of Germany to go to war with France over Morocco clearly involved a British guarantee (under the Entente). Once Belgium was invaded, however, and the neutrality treaty of 1839 defied, all hesitation left him; and never from that moment forward did he doubt that the military machine of the Central European Powers must be destroyed. Thus it was that Mr. Lloyd George entered upon a new phase of his career—that of war statesman.

The first great civilian duty of the War fell on Mr. Lloyd George. As Chancellor of the Exchequer, he had to secure the finances of the country. While Lord Kitchener at the War Office was organising the armies, Mr. Lloyd George had to see that the credit of the country did not collapse. At the very opening of the War he called together the governors of the leading banks and arranged a moratorium which prevented a panic. All the gloomy forecasts of the breakdown of finance so freely indulged in by the opponents of the War were in a moment dissolved into thin air. British finance, thus rallied at the start of the struggle, remained steady throughout; and the good faith thus engendered enabled the Government to borrow the immense sums which alone made it possible to endure and achieve victory. As long as he was Chancellor of the Exchequer, Mr. Lloyd George gave steady attention to this aspect of the war struggle. He knew that war, to be successful, depended, in Milton's phrase, on " two main nerves—iron and gold." His first attention was given to gold. During the first 10 months of the War he remained Chancellor of the Exchequer; and thus on him fell the main financial responsibility. By common agreement of all parties he placed British finance on an impregnable foundation.

The Ministry of Munitions.—It was in June 1915 that Mr. Lloyd George passed from the nerve of gold to the nerve of iron. It was brought to his knowledge that the insufficient supply of shells and guns at the front was exposing our armies to an intolerable inequality of loss. The crisis which followed on the general realisation of this fact in England broke up the Liberal Govt., May 19 1915, and substituted for it the first Coalition administration, of Mr. Asquith and Mr. Bonar Law. The Govt. was entirely reconstituted. Perhaps the most important change was the creation of a Ministry of Munitions—offered to and accepted by Mr. Lloyd George. This ministry was boldly entrusted with the whole function of providing war armaments, hitherto part and parcel of the duties of the War Office. It was natural that the War Office should resent this subtraction from their powers. But it was now quite clear that, in so great a war, the supply of munitions would be a function on a scale so large as to require a separate department. The new enterprise was rather a national movement than an ordinary office of state. The government workshops at Woolwich and elsewhere had been modelled to supply arms for a small peace army. Now that Lord Kitchener was calling forth from the nation by his magnetic appeal an army of 2,000,000 there had to be a corresponding effort to supply them with weapons. In order to achieve this, Mr. Lloyd George put forth all his powers as a democratic o and organiser. He first called on the private armament fir make a new and gigantic combined effort; and they gave splendid support. But this was not enough. He was comp to create a vast network of new factories and workshops, a rally to his effort a huge army of workers, both men and wo He set out to supply the army not only with sufficient shells also with the great guns and explosives rendered necessar Germany's extensive preparations. Above all, he had to c the machine-guns, hand grenades, trench mortars, and equipments which were now absolutely necessary for the effi conduct of a war which was from day to day taking on new t and forms.

Iron and gold were not, however, the only nerves destine be necessary for the winning of the World War. It soon bec evident that it was also to be a struggle of brains. As the spread from end to end of Europe, and afterwards to Asia Africa, it became clear that in this vast struggle statesman was just as urgently requisite as strategy for the full achi ment of victory. Strategy on so vast a scale passed into sphere of statesmanship. Much depended, for instance, on moral appeal to the world against the aggression of Germ There Mr. Lloyd George, with his golden gift of oratory, a leading part from the beginning. He helped gradually detach Italy, and widely affected opinion in all the neutral c tries. It was one thing to raise so gigantic an army. It another thing to apply it to its full use and value. On all t questions Mr. Lloyd George in 1915–6 held vigorous views. was not content to confine himself to the function of crea guns and shells. In the beginning of 1915 he began to pour to the Cabinet a succession of memoranda, in which he end oured to put before them the full seriousness of the military ation following upon the collapse of the Russian attack in spring and summer of 1915. The theory of the " Russian st roller " had proved very comforting to depressed English during the winter and spring of 1914–5. But when the Ger advance swallowed up Warsaw and Brest-Litovsk, it bec clear that the " steam roller " was not even a good sickle; that Great Britain would have to rely upon herself. The fai of the Gallipoli attack in the latter part of 1915 only emphas the same point. It began to look as if victory would depend so much on numbers as on skill; and all Britain's great ar and splendid armaments might only increase the magnitud her defeat if such enterprises were repeated.

Mr. Lloyd George and the Eastern Front.—The policy strategy laid before the Cabinet in the Lloyd George memora in the year 1915 were never fully adopted. In the language the time, the Cabinet was divided between " Westerners " " Easterners "—those who looked for a decision only on Western Front, and those who believed that victory could quickened by transferring part of our effort to the Near E It all ended in a compromise which resulted in the expediti to Salonika. But Mr. Lloyd George aimed at something larger—nothing less than a considerable diversion of armies fr the West to the East of Europe. He proposed and contempla the diversion of an army of at least 1,000,000 from the West to the Eastern Front. With the development of the Germ submarine warfare Mr. Lloyd George's Eastern idea became l and less practicable; and with the increase of the German arm the danger of a German break-through on the West finally h the British armies to their task. But in early 1915 these fa had not been fully disclosed.

As the year 1915 advanced, Mr. Lloyd George's general d content with the conduct of the War grew stronger with ev month. It extended to home policy as well as foreign. He sa for instance, that if the generals were to have their way and sta the whole issue on a break-through in the West they would requ to be provided with an incessant flow of men. The first respon to Lord Kitchener's appeal had been magnificent, and so 2,000,000 volunteers had flocked to the colours. But then ca a pause in the recruiting; and yet the fearful wastage continued and grew worse. The policy of frontal attacks begun at Ne

ıpelle clearly meant a continual supply of vast armies. Such
ıies, Mr. Lloyd George now began to perceive, could not be
ıred by the voluntary principle alone. Having once made up
mind on that point, he became a vehement advocate of con-
ption in the autumn of 1915. But Liberal sentiment was
inst it, and Mr. Asquith hesitated. A series of experiments,
wn at the time as the "Derby Schemes"—distinguishing
ween married men and single—were attempted from month
nonth. Mr. Lloyd George advocated the American ballot.
the military councils were not in favour of it. Then came
er plans—such as "starring" and "unstarring" of men
ording to their callings and occupations.

ut all these makeshifts ended in leaving a sense of inequality
unfairness which could only be removed by a more compre-
sive policy. So at last Mr. Lloyd George swung the Cabinet
conscription; and only one minister—Sir John Simon—
gned. Everything possible had now been done to supply the
erals both with men and with munitions. But the question
olicy remained, and there Mr. Lloyd George's discontent
tinued to grow. The tragic death of Lord Kitchener by the
ing of the cruiser H.M.S. "Hampshire" on June 5 1916
ted a vacancy at the War Office which could only be filled
ne way. So in that month Mr. Lloyd George passed from the
istry of Munitions to the War Office. In this new position
ower he obtained a firmer grip on the military machine at
front, and in particular he carried out a drastic reform of
munications in France.

rom these lesser tasks his mind was diverted to the main
e of victory or defeat by the tremendous tragedy that befell
Allied cause in the autumn of 1916. Rumania, tempted by
sia into the War on the side of the Allies at an unseasonable
nent, was violently attacked by the great German general
ckensen and dramatically crushed before the eyes of her dis-
and helpless Allies. In vain Mr. Lloyd George appealed to
Cabinet to make some effort to save Rumania. Italy had
red the War in the previous year, and the Russian armies
still in being—could nothing be done? Nothing was done;
for the moment Rumania was blotted out. But the event
a profound effect on the mind of Mr. Lloyd George. It
ght him to the parting of the ways. "Is it necessary," he
to say, "that a little nation should be laid on the altar of
war every Christmas? It was Serbia in 1915, now it is
nania. What nation will come next?" Possessed with this
d, he decided to raise the issue in a definite form, and on
ay, Dec. 1 1916, he laid his views before Mr. Asquith.

ollapse of the Asquith Govt.—His main contention was that
rge a War Committee as then existed could not conduct the
to victory. He proposed a smaller and more efficient body
ree or four men, solely devoted to this one object of winning
War. What was wanted was unified and unsleeping control.
he proposed—and here was the crux of the political situa-
—that the existing Prime Minister should not be chairman
e committee. That was where the dividing line came. For
kly and definitely Mr. Lloyd George had ceased to believe
r. Asquith as war leader. Mr. Asquith's pride was touched
e quick; and it was quite clear that he profoundly resented
proposal, although he himself had first named Mr. Lloyd
ge as chairman of the new War Committee. On Saturday,
2, Mr. Lloyd George was under the impression that his
osal had been accepted. But friends intervened on both
: the Northcliffe Press in favour of Mr. Lloyd George, and
Asquith's friends in favour of a chief whose loyalty has
ys commanded a fit return of personal devotion. On Mon-
Dec. 4 1916, *The Times* published a leading article display-
xultation over Mr. Asquith's defeat, and immediately Mr.
ith wrote to Mr. Lloyd George breaking off the agreement.
e afternoon of that day Mr. Asquith resigned office. He
ved authority from the King to form a new Ministry. He
to Mr. Lloyd George asking him to join on condition that
Mr. Asquith—as Prime Minister must be chairman of the
War Committee. Mr. Lloyd George refused that condition,
laced his office at the disposal of Mr. Asquith.

Already, on Sunday, Dec. 3, the Conservative rank and file had met. They had decided at first against following Mr. Lloyd George, whereupon Mr. Bonar Law had emphatically said that, in that case, they could not count on his leadership. He and his friends refused to join the new Ministry, and so Mr. Asquith's efforts to reform his Coalition without Mr. Lloyd George broke down. The King then sent for Mr. Bonar Law. But as some of the Liberals and the Labour party refused to support him, he too failed to form a government, although Mr. Lloyd George offered to serve under him. The King then called a conference at Buckingham Palace and tried to form a new Coalition Ministry under Mr. Bonar Law, with the offer of the Woolsack to Mr. Asquith. Mr. Asquith refused. Thereupon the King sent for Mr. Lloyd George, as he was clearly the only possible Premier.

MR. LLOYD GEORGE AS PREMIER

The New War Policy.—There was nothing left for Mr. Lloyd George but to accept the call. He attempted to rally all parties behind him. He succeeded with the Conservatives and the Labour party, and a certain number of Liberals. But the bulk of the Liberal ex-ministers stood aside and began to form a group known as the Independent Liberal party. Mr. Lloyd George was now in sole command of his own war policy. The small war committee which he instantly appointed fully carried out the hopes of its founders. It sat from day to day, and very often twice a day. It practically took the place of the Cabinet. Records were kept of its meetings, and Mr. Lloyd George formed a small Downing Street secretariat in order to keep in close touch with the various Ministries. The result was a general quickening up of war decisions and a more decisive control of the whole machine of government.

During the year 1917 Mr. Lloyd George pressed forward his idea of unified command of the Allied armies. He was now completely convinced that the War could only be won if the Allies were to face Germany with the same concentrated authority that Germany had established over her own partners. He was faced, however, with a very steady resistance from the high military command, now from time to time supported by the Independent Liberal party. There was a strong national sentiment against subordinating our armies to the control of foreigners, and there was a firm belief among the soldiers that they could win the War alone by pounding harder at the Western Front. But as the year advanced the sanguine expectations frankly thrown out in interviews in the spring by Sir Douglas (later Earl) Haig were not fulfilled. The Aug. fighting round Lens; the Sept. onslaughts on the east and north of Ypres; finally the assault on Passchendaele—all these battles displayed fully the inexhaustible valour of British, Australian and Canadian troops. But there was no break-through. The British armies were checked by the mud and rain of the Flanders autumn, and in too many cases heroism was literally choked in slime. Mr. Lloyd George contemplated this wastage of Brittish manhood with increased impatience, and on many occasions protested against the sacrifice of volunteers and conscripts.

On Oct. 24 1917 there occurred an event which finally decided him to force the matter of unified control to a decision. On that day the Austro-German armies under Von Bülow broke through the lines of the Italian armies dangerously stretched out between the Eastern Alps and the Adriatic Sea, and drove them back to the line of the Tagliamento with the loss of 300,000 men and 2,000 guns. Italy stood for the moment in peril of a defeat equal to that of Serbia and Rumania in the preceding years. Mr. Lloyd George was determined that this defeat should not take place. He himself journeyed immediately to Italy. By infusing new courage into the Italians he helped to check the confusion and flight of their armies. He compelled the Western commands to send an army of infantry and artillery, English and French, under Gen. Plumer through the Mont Cenis tunnel to northern Italy. These reinforcements arrived in the nick of time, checked the collapse of Italy, and aided greatly to save her from defeat.

The End of the War.—Having achieved this task, Mr. Lloyd George, with characteristic swiftness, determined to press on with the matter of unified control. On his journey back to England he stopped in Paris on Nov. 12 1917 to make a speech in which he plainly announced that divided control meant defeat. But that speech for the moment only aroused fresh opposition, and when he returned to Parliament he had to face the vehement criticism of the Independent Liberals led by Mr. Asquith. Yet, later, in May 1918, when Sir F. Maurice, challenged his authority in a letter to *The Times*, the consequent vote of confidence in the Commons secured him a decisive majority of 187. But full unity of control was not really achieved until the terrible events of March 1918 brought home to all parties in England the nearness of the peril. During the winter the Germans brought across Europe a fresh army of 2,000,000 men released by the collapse of Russia after the Bolshevik revolution of Oct. 1917. This gigantic new army created a fresh situation in the West, and the first blow fell on March 21, when 40 German divisions attacked and broke through the British line west of St. Quentin. On the following days the British line withdrew 15 m., and the military struggle that followed lasted through five terrible months. Mr. Lloyd George threw into the fighting line all those youthful regiments which he had hoped to keep for home defence. Even so, the German pressure very nearly crashed through to the sea. There was a tense moment when some high military authorities were in favour of bringing the British armies back to England. But Mr. Lloyd George always strenuously refused to face such a possibility. He averted defeat by two principal steps of policy. One was the assertion of full unity of control, and the other was the bringing over of the American armies.

President Wilson had not contemplated sending his armies to Europe until they were fully trained and brigaded. But that process could not have been finished till 1919 at the earliest, and it was now clear that in that case the American armies would be too late. Mr. Lloyd George therefore made a definite appeal to President Wilson to send all he could immediately, and the President instantly responded by a promise to do so on condition that Great Britain provided the transport. Thus with the combined effort of the American command and the British Navy and Marine no less than 2,000,000 American soldiers were carried across the Atlantic, in spite of the submarines, during the months of April and May 1918. Those numbers now enabled the Allies to meet the Germans with a greater sense of numerical equality. But mere numbers were still useless without unity. Visiting France in the first week of May 1918, Mr. Lloyd George held a decisive combined meeting of the military and civil powers, in which, supported by Lord Milner and M. Clemenceau, he was at last able to persuade the British generals to accept the supreme command of the great French soldier Marshal Foch. During the final months of the War the British armies fought loyally under that command. It was by the combined attacks of British and French troops, storming the German lines east of Amiens, that the tide was turned on Aug. 8 1918. Seven great battles were fought after this event, but from Aug. till Nov. the German armies were steadily driven back. Finally, on Nov. 11, came the collapse of the German resistance and the acceptance of armistice terms of defeat by the new German Government. "Germany is doomed," cried Mr. Lloyd George, speaking at the Mansion House on Nov. 9 1918, and he proved a true prophet. The Allies had won the War.

The Peace Conference.—Victory having been achieved, it now remained to make peace. There were inevitable delays. Mr. Lloyd George deemed it necessary first to strengthen his position by an appeal to the country. The polls took place on Dec. 14 1918, and the results were declared on Dec. 28. The effect was an overwhelming victory for Mr. Lloyd George, he being returned to power by a majority of 249 over all the independent groups. He himself was returned for the eighth time as member for Carnarvon Boroughs with a majority of 12,898. These events filled up the pause rendered inevitable by the waiting of Europe for the arrival of President Wilson, who had decided to attend the Peace Conference as American representative. The next step was the choice of the capital in which to hold the Peace Conference. Paris was selected, the intention being to move on to Geneva after the first stage. But once settled in Paris it
found impossible to move so vast an assembly of nations.
first meeting of the conference took place on Jan. 18 1919 a
Palace of Versailles, and it proved an impressive gatheri
the representatives of all the 30 countries who had taken pa
the defeat of the Central Powers. Mr. Lloyd George took
him from England a joint delegation representing all pa
including Mr. Bonar Law, Mr. Balfour, Lord Milner and
George Barnes. A powerful delegation came from the Do
ions, including Mr. Hughes, Premier of Australia, Sir R
Borden and Gen. Botha. Thus the whole British Empire
represented at Paris among the colleagues of Mr. Lloyd Ge

It soon became obvious that so big an assembly coul
really arrive at peace. There were too many conflicting v
there was no possibility of secrecy. The allied negotiators g
ally narrowed to an inner council of ten, which was soon red
to five; then from five to four; and finally from four to th
Mr. Lloyd George, President Wilson and M. Clemenceau.
them fell the full burden of making the peace. This num
narrowing of the peace negotiators, together with the inc
of secrecy, created widespread discontent among those wh
been led to expect a peace by open diplomacy. What happ
behind the scenes was this: roughly speaking, the position
that Mr. Lloyd George and President Wilson worked for a
of conciliation, while M. Clemenceau worked for a peace o
tory. The French started with a claim to extend their fro
up to the left bank of the Rhine. Wilson and Lloyd G
together succeeded in moderating this claim. But they
compelled to hand over the Saar Valley for 15 years as pa
the compromise. Smaller compromises took place in rega
Silesia and the Polish corridor. No one was completely satis
but every country had its say. President Wilson's unique
tribution to the settlement was the League of Nations Cove
Though Mr. Lloyd George took great interest in the frami
the Covenant, he left the chief British share in its mouldi
Lord Robert (later Viscount) Cecil, who sat on the League
mittee as the British representative. But when the crisis
and President Wilson threatened to leave the conference
the Covenant was placed first in the treaty, Mr. Lloyd G
supported the view of President Wilson.

The Treaty of Versailles.—Mr. Lloyd George's freedom
much hampered by Press attacks from home, and at one mo
Lord Northcliffe organised a mandatory telegram from ove
members of Parliament rebuking him for a tendency to we
on the demands to Germany. Mr. Lloyd George returne
London to face his critics in Parliament and secured a
majority. There can be no doubt, however, that these symp
of discontent at home diminished his authority and weak
his resistance to the military policy of France. At this
for instance, he agreed to the French claim to occupy the
bank of the Rhine for 15 years, which he had hitherto attem
to limit to a much shorter period. On May 6 a draft of the t
was completed, and was presented to the German Foreign
ister, Count Brockdorff-Rantzau on the following day. Ger
instantly pleaded for various important modifications. D
the six weeks of parley with Germany that followed Mr.
George played the part of conciliator. President Wilson
ened against Germany, and took the view that he was ple
to the treaty as it stood. Mr. Lloyd George secured the softe
of many harsh terms, and in that way prepared the groun
the return of the spirit of conciliation to Europe. A poli
crisis in Germany followed, but on June 22 the National asse
authorised the signing of the treaty, and on June 28 it was s
at Versailles by the German envoys. Mr. Lloyd George retu
to England and defended the treaty before Parliament, w
unanimously ratified it on July 3. Shortly after he was awa
the Order of Merit.

Domestic Discontents.—Having made peace abroad, Mr.
George returned to restore peace at home, which was jus
much in peril. The long strain of the World War and the
rible losses of men and material had left Great Britain gra
wounded and weakened. The impulse of patriotism pa

av; and the idea seemed to spread that every class was to be abled to "get rich quickly" by the achievement of victory. ie result was a series of industrial struggles, beginning with the ndon railway strike in Feb. 1919, followed a few weeks later the first of the coal crises. Mr. Lloyd George averted a strike the coal-fields by appointing a royal commission with Mr. stice Sankey as chairman, with a promise that the commission ould report on wages and hours by March 20. The Sankey nmission reported on that day, recommending a two-shillings' rease in wage and an immediate seven-hours' day. The consions were granted and a strike was averted. But when the jority of the commission went on to recommend nationalisa- of the mines, Mr. Lloyd George refused to adopt the sugtion. In Oct. 1919 the railwaymen precipitated a national ke; and once more Mr. Lloyd George had to play the part of ional conciliator. He brought the strike to an end by a commised settlement fixing wages according to the scale of living. uring the next two years the Lloyd George Coalition Govt. sed a series of agreed measures on housing, suffrage and land. as time went on it became clear that the country was finanly more exhausted than had been supposed. The first afterr "boom" gradually passed into a "slump," and there arose n the whole country a cry for economy which expressed itself n "Anti-Waste" campaign of the utmost vigour. By-elec after by-election was lost to the Government, and the counwas swept by financial panic. Mr. Lloyd George met it by rastic measure. He appointed a small committee, with Sir Geddes as chairman, to revise the whole of our national nce. As a result of its sweeping report—the "Geddes Axe" idespread economies were effected in all departments. The cultural subsidy was withdrawn and the agricultural wages rds were suspended. The housing scheme was held up: and rogress in education was checked.

all of the Ministry.—Those concessions weakened the Radical ort of the Coalition. In the autumn of 1922 a similar weakg occurred on the Unionist wing of the Conservative party g to the policy to which Mr. Lloyd George was driven in nd by the course of events. The Sinn Fein trouble which broken out in the later period of the War worked up in 1920–1 n actual rebellion. All Mr. Lloyd George's efforts to effect mpromise between Northern and Southern Ireland proved . In the spring and summer of 1921 the condition of Iregrew rapidly worse. Murder and outrage were rampant. Coalition Govt. initiated a special force, who received the name "Black and Tans," to deal with the violent methods he Sinn Feiners by vigorous reprisals. This produced in land a divided feeling as to the equity of the struggle. In autumn of 1921 peace overtures began to pass from one to the other. Mr. Lloyd George decided to make a real t after a settlement. A truce was declared, and the picked ers of Sinn Fein came to Downing street, where, after several s of discussion, a settlement was reached, at midnight, Dec. 21. This great concession to Ireland was followed by resist- to the Turks at Chanak on the Dardanelles (Sept. 1922), the two events produced the downfall of the Lloyd George ition. The Unionist party, created on the principle of rence to Home Rule, was riven asunder by so great a concession at of Dominion Home Rule to Southern Ireland. The t of renewed war with Turkey was profoundly unpopular, presented the enemies of the Govt. with an opportunity. Bonar Law, who had retired from the Govt., returned to eting of the Conservative party at the Carlton Club on Oct. 22, at which it was decided that the Conservative party d leave the Coalition. Mr. Lloyd George instantly red, and in the election that followed (1922) Mr. Baldwin— succeeded on the death of Mr. Bonar Law—obtained a rity. (*See* English History.)

An Opposition Leader.

roughout the vicissitudes of the general elections which ed in the autumns of the following years (1923 and 1924) loyd George remained a leader of opposition. He reunited his followers with the Independent Liberals after the election of 1922, and devoted his energies to identifying the Liberal party with a policy of economic reconstruction. In 1924 he published *Coal and Power*, which outlined a comprehensive scheme for the more efficient utilisation of the natural resources of the country. Nevertheless the reunited Liberal party failed to gain strength and in the General Election of 1924 its numbers in the House of Commons, controlled by Mr. Asquith and Mr. Lloyd George, sank to 40 members. Mr. Lloyd George continued his active efforts to rouse the country to the need of further domestic reform to meet the home crisis: and in the early autumn of 1925 he issued a big land programme which he proceeded to advocate throughout the country.

By the elevation of Mr. Asquith to the peerage as the Earl of Oxford and Asquith (1925) Mr. Lloyd George earned the succession to the Liberal leadership in the House of Commons, and was elected to that office in the sessions of 1925 and 1926. In Feb. 1926 he carried his land proposals, with few modifications, through a Liberal Convention assembled at the Kingsway Hall in London. But the Liberal party still showed no signs of revival in the country, and in the by-elections of Jan. and March 1926 some of the Liberal candidates lost their deposits to the returning officer. Still, the personal position of Mr. Lloyd George in the country was growing steadily stronger: and his criticism of Sir Austen Chamberlain's new Locarno policy in the House of Commons in March 1926 created a profound impression. His national and parliamentary position was in strange contrast to the size of his following; and that created a strange diversity of opinion in the forecasts of his future. In May, during the course of the general strike, Mr. Lloyd George expressed opinions that were not in accord with those of Lord Oxford and the other Liberal leaders. His idea was that the Government should negotiate with the strike leaders without delay, instead of declining to do so until the strike had been called off. He ridiculed the view that the general strike was aimed at the constitution. A somewhat acrimonious correspondence between him and Lord Oxford followed, and the party, both in and out of the House of Commons, was acutely divided upon the question. (*See* Liberal Party.)

Mills, *David Lloyd George, War Minister* (1924). (H. Sp.)

GEORGE, STEFAN (1868–), German poet, was born at Büdesheim, Hesse, on July 12 1868. After attending the grammar school at Darmstadt, he studied philosophy and the history of art in Paris, Munich and Berlin. He travelled extensively in Italy, France, England, Spain, Holland and Belgium and became associated with the Baudelaire and Mallarmé School in Paris and the disciples of the Pre-Raphaelites in London. His early poems were first published privately for a select circle of friends, for whom in 1892 he founded the *Blätter für die Kunst*. George's poetry which is non-realistic, reflects a heroic and aesthetic world-philosophy; and possesses great beauty of form and an austere power. Among his works are *Hymen* (1890); *Algabal* (1892); *Die Bücher der Hirten* (1895); *Jahr der Seele* (1897); *Die Teppich des Lebens* (1899); *Tage und Taten* (1900); *Die Fibel* (1901); *Der siebente Ring* (1907); *Stern des Bundes* (1914); *Der Krieg* (1917); *Drei Gesänge* (1921). He also translated Baudelaire, Dante and the sonnets of Shakespeare.

See L. Klage, *Stefan George* (1902); F. Düberg, *Stefan George* (1908).

GEORGIA, U.S.A. (*see* 11.751).—The population of Georgia in 1925 was 3,058,260, as against 2,895,832 in 1920 and 2,609,121 in 1910, an increase of 17·2% for the 15 years. During 1910–20 negroes increased from 1,176,987 to 1,206,365, but relatively they decreased from 45·1% of the total population to 41·7%. The urban population was 25·1% as compared with 20·6% in 1910. The density of population in 1920 was 49·3 per sq. m. as against 44·4 in 1910. The census of 1920 revealed an important movement of population from the mountain counties of the northern portion of the state and from central Georgia to south-central and southeastern Georgia, due to the presence of large areas of undeveloped and fertile land in the southern half of the state. The highest density of population, however, was still to be found in the northern half.

Agriculture.—Although scarcely perceptible in 1914, by 1916 the boll weevil had spread over the coastal plain of Georgia, and in the following years covered the entire state. The growing of long-staple cotton was abandoned and the production of the short-staple was sharply curtailed, falling from 2,718,037 bales in 1914, the largest crop in the history of the state, to an average of 30% less in the four years following. This situation gave a powerful impetus to diversified farming, the movement being aided by the high prices of foodstuffs due to the World War. The most important of the new crops is tobacco. Beginning with a production of 1,088,000 lb. in 1910, this crop in 1925 had grown to 47,880,000 pounds. Meanwhile there have been tremendous increases in the production of hogs, sweet potatoes, peanuts, melons and fruits, particularly peaches and apples, and pecans.

Education.—In 1910 the total enrolment in the public schools was 555,794; in 1924, 709,760; the state appropriation for elementary schools in 1910 was $2,237,000; in 1925, $4,500,000; there was raised by local taxation in 1910, $1,307,000; in 1924, $8,732,923. The total amount spent from all sources for elementary schools in 1924 was $22,701,973. Laws were enacted 1910–20 for the modernising of the educational system. A constitutional clause limiting the taxing power of the counties to taxation for elementary schools only was removed (1910). The state Board of Education, hitherto composed of state officials, was made a professional board (1911), and a uniform text-book law passed, the duty of selecting the books being placed upon the board. Compulsory education dates from 1916. The law, as amended by the new School Code of 1919 required attendance through the seventh grade. Provision was made for attendance officers. A training school for negro teachers was authorised in 1922. The Federal Smith-Lever Act of 1914, and the Smith-Hughes Act of 1917, both accepted by Georgia, provided for extension work in agriculture and home economics, and for the teaching of vocational subjects in the schools.

In 1919 the policy was adopted of setting apart one-half of the total income of the state for the schools. In the same year a constitutional amendment was adopted, by which the counties were required to levy local taxation of not less than one mill nor more than five mills for the support of elementary schools as a supplement to the state appropriation. To encourage the consolidation of small schools, the Legislature appropriated (1919) $100,000 from which the state offered to pay annually a bonus of $500 to any county which combined small schools into larger ones and where a four-year high school was provided, an additional bonus of $1,000 was authorised. This bonus fund was increased to $200,000 in 1924. An illiteracy commission was established (1919) to make a study of adult illiteracy and in 1920 local taxation for the support of schools for adult illiterates was authorised. Noteworthy progress was being made in the eradication of illiteracy. White illiteracy declined from 7·8 to 5·4%; negro from 36·5 to 29·1%. During the period 1905–25 the number of four-year high schools increased from 7 to 275. The total state appropriations for higher institutions, including the district agricultural schools, the academies for the blind and deaf, and various training schools for defective classes, was in 1910 $436,500; in 1924 $1,284,450.

Government.—The period 1910–25 in Georgia was characterised by legislation designed to further social progress and economic improvement. The standard of medical education was materially raised (1913); only four-year medical colleges were recognised and the requirements for entrance were increased. A new Board of Health was established (1914) to exercise control over the county boards of health. Provision was made for paid sanitary commissioners in all sanitary districts, which consist of one or more counties. A Vital Statistics law of 1914 provided for the registration of births and deaths and the publication of statistics.
The employment of children under 14 years of age was
hibited (1914), and factory inspectors were provided in
A Training School for Mental Defectives was established
and a state Board of Public Welfare (1919) was set up, char
primarily with the duty of inspecting all state institutions
the dependent, defective, delinquent and criminal classes.
Act of 1920 provided for rehabilitation of persons disable
industry or otherwise, assented to the Federal Vocational
and pledged the state to equal appropriations made by
United States. A state Board of Vocational Education
created (1917), charged with the administration of the reha
tation training. In 1922 a Commission was created to st
the laws of this and other states and propose legislation
safeguard the welfare of children within the state.

A Dept. of Commerce and Labour was created (1911)
which was later (1917) included a free employment bu
The Dept. of Insurance dates from 1912. The State High
Dept. (1916) was reconstituted in 1919 to bring the state sys
into harmony with national legislation providing aid in
construction of rural post roads. A Bureau of Markets
was created to gather and disseminate information of valu
producers and consumers of agricultural products; and, in
an Act was passed to encourage co-operative marketin
agricultural products, their storage, canning, packing, etc.,
supplying of agricultural machinery, and the financing of
operations. To further the erection of modern warehouse
the weighing, grading and storage of lint cotton, a Wareh
Commission was authorised in 1918. A new banking
(1920), modelled on the National Bank Act, corrected
defects in the old banking system and provided for adeq
inspection. An Employers' Liability Act (1920) set aside
common law defence of contributory negligence of fe
employees and provided for compensation for industrial
dents, a commission being created to administer the Act.
Uniform Negotiable Instruments law was adopted in 1924.

Finances.—The assessed value of the taxable propert
Georgia in 1910 was $766,000,000 and in 1924, $1,213,423
The yield of taxes in 1924 was $16,765,264. The prin
source of revenue was the general property tax. In recent
two special tax commissions appointed by the governor
made reports urging the classification of property for tax
purposes, the adoption of the income tax, and other chang
the system; but the Legislature had up to 1925 failed to
The bonded indebtedness of Georgia was reduced from $6,94
in 1910 to $5,284,202 in 1924.

History.—The governors of the state during the period
26 were: Hoke Smith (Dem.), 1911–2 (shortly after his inau
tion Smith was elected by the Legislature to succeed
Terrell as U.S. Senator); Joseph M. Brown (Dem.),
(elected at a special election to fill Smith's unexpired
John M. Slaton (Dem.), 1913–5; Nathaniel E. Harris
1915–7; Hugh M. Dorsey, 1917–21; Thomas W. Har
(Dem.), 1921–3; Clifford M. Walker (Dem.), 1923–. (R. P.

GERARD, JAMES WATSON (1867–   ), American lawy
diplomat, was born at Geneseo, N.Y., Aug. 25 1867. Ed
at Columbia University and at the New York Law Sch
was admitted to the bar in 1892 and began to practise
York City. In 1908 he became associate justice of the Su
Court of New York, resigning in 1913, on being app
ambassador to Germany. At the outbreak of the World
1914 he assumed the care of British, Japanese, Ruman
Serbian interests in Germany, later visiting the camps
British and other prisoners were confined and doing
alleviate their condition. His responsibilities were furt
creased by the fact that German interests in France,
Britain and Russia were placed in the care of the A
embassies in those countries, the American embassy in
thus becoming a sort of clearing house. After the sinkin
"Lusitania" with many Americans on board, on May

e American ambassador's position became more difficult, and ally, on Feb. 3 1917, diplomatic relations were broken off by nerica and he was recalled. While in Germany in 1914 he was mocratic nominee in New York for the U.S. Senate, but with- t success. On his return to America he resumed the practice of v in New York City. He received the vote of several states in Democratic National Convention of 1920 and 1924 and was airman of the Finance Committee of the National Demo- tic Campaign in 1920 and Treasurer in 1924. In 1917 he pub- ed *My Four Years in Germany* and in 1918 *Face to Face with iserism.* For his services to England he was decorated with G.C.B.

ÉRAULT-RICHARD, ALFRED LÉON (1860–1911), French rnalist and politician (*see* 11.766), died Dec. 6 1911.

ERMAN LITERATURE (*see* 11.783), like every form of spirit- activity in Germany, experienced between 1910 and 1920 p alterations in thought, feeling, values and form. Charac- istic of the older generation was its pleasure in the external ture of the world. Man, with joy and confidence, felt himself art of this picture. The younger generation seeks to reveal inner meanings of the world. A time of suffering leads towards nite horizons. Former standards of measurement are replaced a sense of the immeasurable. We no longer tread our bit of world as a solid piece of reality, but long for escape into the nite. Its symbol is the horizon always receding, never attained.

he Forerunners of Expressionism.—But what appears at first it to be a bridgeless gap made by disruption is really only the stage of a continuous development already begun between o and 1910. During those two decades the point of view had ted, gradually but steadily, until by 1915 it already had come -circle. All typical writers of the "impressionist" period turned symbolists in their later works; Stefan George and circle, or Rainer Maria Rilke, Gerhart Hauptmann himself is later work (*Und Pippa tanzt, Emanuel Quint*) are only to understood from this angle. Even when "impressionism" at its height there were writers whose work was strange to r age, and only later became quite intelligible when they e seen as the forerunners of an age of "expressionism." In on, Hermann Conradi, Johannes Schlaf, Hermann Stehr and ob Wassermann looked towards new life and personality; le Julius Hast, Paul Scheerbart and Gustav Meyrink strove new form and shape; and Heinrich Mann's evolution from aissance poet to Central European democrat meant increas- sympathy with the New Youth. Dramatists had already mpted to create a new drama of style to break the suprem- of the old naturalistic drama of situations or the neo-ro- tic drama of sentiment. Herbert Eulenberg and Wilhelm midtbonn had dared to make a new drama out of passion or tement; Paul Ernst in a hard struggle for dramatic form ght to create a new classical drama, and thereby was first in far-reaching fight against the dominant relativist and psy- logical cult. Frank Wedekind had broken with every tradi- and spoken with the voice of primitive impulse. While lyric poets, Peter Hille, Alfred Mombert, Christian Morgen- n, had one foot in the field of the new art, others from 1900 ards took their full stand on that ground. Instance the poets *haron*, particularly Otto zur Linde (b. 1873, *Collected Works*, *seq.*), Karl Rottger and Rudolf Paunwitz.

he Expressionist Movement.—The term "expressionism" pplied to the theory and practice of this new art came into ral use between 1910 and 1920. The word is, on the whole, itous. It shows clearly how the new art contrasts with nat- istic impressionism which was all facts and feelings; as lly with aesthetic, neo-romantic fantasy; opposed thus to and Hoffmansthal alike. Instead of the Impression received without we have now Expression of the inward self. In- d of transcribing some trait of nature that awakens a certain of feeling, we have relief of the spiritual tension that con- es all concrete things as signs and symbols devoid of separate ning and even of incidental help towards the better recogni- of the outward world. Instead of being the humble inter- er of any outer thing, the artist's idea now absorbs the object in order that he may free himself from its tyranny and find his own salvation in the Idea. Instead of pleasure in the object, pleasure that enlightens or transfigures, there is now torment from which respite must be won if life is to be borne. Eternal circumstance yields to the eternal act; the cool observer to the ardent believer and worker in a holy cause; the poet to the political leader; description and eloquence to pathetic appeal, even to the stream of pain. Earth and nature yield to Spirit, to the All, to God; positivism to metaphysics and rationalism to the irrational; logic to mysticism, understanding to use, potential ability to active will and decided opinion; form to matter; society to community, the logical and psychological man to the inspired. In short "I" yields to "You" and "One Another;" the mistrusting mood to the trustful. For: "Man is good;" "Man is the centre of his world;" "With man the world begins."

In the history of ideas the new sweep of tendency is thus a variety of those foaming, overflowing movements known in Germany as "Sturm und Drang" or "romanticism." Chronologically, it is the expression of the inevitable change from one generation to another. This new art had, indeed, leaders older than itself; but in the main it manifests the spirit of the New Youth—its will to live, its urge towards artistic creation.

The generation born between 1880 and 1890 or later breaks clean away from its predecessors born in the 'sixties or thereabouts. But what this fresh generation feels, and means to prove, is that its break with the immediate past is something fundamentally different from the new departures of 1880 or 1840 or 1800. This artistic revolution stands out against the world's more profoundly significant background. It begins with a far different spiritual atmosphere—itself only one aspect of a whole world's violent moral crises. Before this, the revolts of Youth against Age were familiar enough, but really meant bolder advance on lines marked out by the fathers, and by the forebears for 400 years. This time the standpoint is quite changed. It is impossible, says youth now, to link up with our predecessors. Their past is worthless; the present is a disgrace; our task to-day is to "break all bridges and begin again." The naturalistic revolution of its fathers is regarded as a false development by their sons who overthrow it. To them it seems merely the last stage of a process set up a century ago or even four centuries ago, when the epoch of Humanism began to make the world "measurable and ponderable." Now, the aim is to make a new beginning.

The former phase displayed the victorious advance of the natural sciences, their processional entry, as it were, into human life, their permeation of all its knowledge, feeling, thought, activity. The resultant rise of machine-industry and technical resources gave an unparalleled command of nature by man. The young generation proclaims the end of this era in a Europe that went to pieces in the World War. It mocks the so-called mighty achievements which only led to unexampled violations of the spirit. This is why they reject and execrate the idols of science and repudiate its votaries, the brain, the head. This is why they acclaim as prophets the idol-breakers Strindberg and Claudel. This is why they reject the "law of causality" in literature, together with the materialist theory of the soul, and the correspondent psychology. Hence, from their language, they banish logic and sweep away the parts of speech like articles and copulatives, which merely serve logical uses. They rather look to children and savages for instruction in the principles of true and direct existence.

Simple as these principles appear on the one hand, not all the young talents are fully able to adapt them, but, on the other hand, they lend themselves to many varieties of imaginative and reflective creation. There is room not only for the despisers of culture and civilisation, but also for those who, like the "futurists," hope to create a new art by the enhanced employment of all new technical possibilities; room no less for a leading expressionist writer of fiction like Alfred Döblin, who answers the almost fashionable derision of modern science by protesting that the need is for "more and more natural science." Besides expressionism of the Western types there is an Eastern cult; while one school is actively political another is mystical and abstract;

while an international school calls for a new humanity, a German school demands a new German type of humanity. These groups are not susceptible to such clear local distinctions as in painting, where the Munich set of the "Blauer Reiter" stands apart from the Dresden "Brücke" set. The Prague group, with Meyrink, Brod, Kafka and Werfel, is perhaps more Eastern and mystical, the group assembled in the *Aktion* in Berlin more "activist" and political. But Berlin is also the home of the poets of the *Charon* and of the *Sturm*, the one an essentially Nordic-Germanic cult of metaphysical "expressionism" while the other bears the stamp of abstract internationalism.

The First Phase of Expressionism.—In point of time, the new literary movement falls mainly within the decade 1910–20. It broke through in two main thrusts. With "manifestos" and "radical strophes" the "apocalyptic striplings" led the onset. Kurt Hiller in Berlin gathered adherents into the "Neuer Klub," the "Gnu" and similar associations; he collected their verses in the *Condor* in 1912. Franz Pfemfert welcomed them in the *Aktion*, Alfred Richard Meyer in the *Bücherei Maiandros* and in his *Lyrische Flugblätter*. So Paul Zech in *Das neue Pathos*, Ernst Blass, in Heidelberg, in *Die Argonauten*, Herman Meister in *Saturn*, and he also published in the *Flut* collection a first *Anthology of the Most Recent Belles Lettres*. In Munich two of F. S. Bachmair's periodicals were entitled *Die Revolution* and *Neue Kunst* respectively. But this poetry, especially at first, often betrayed the influence of George and Rilke in form, and still more in rhythm; although, straining out beyond it. Not for nothing were the new periodicals which Dauer began to issue in Berlin in 1910 and 1911, called *Der Sturm* and *Die Aktion*. After these two, the most important periodical of the new school was the Leipzig *Weisse Blätter*, which first appeared in the autumn of 1913. The many-voiced yearnings of the time, their yeas and nays, find their most emphatic, clearest and purest artistic utterance in Theodore Däubler's three-volume epic *Das Nordlicht* (1910), Otto zur Linde's *Collected Works* (1910 *seq.*), Franz Werfel's poems (*Wir Sind*, 1913), the verses of Georg Heym, Georg Trakl, Ernst Stadler, Gottfried Benn, August Stramm, Carl Sternheim's dramatic work, Reinhard Johannes Sorge's *Bettler* (1912) and George Kaiser's *Die Bürger von Calais* (1914). Already at this time, just before the War, a new publishing house on a large scale (Kurt Wolff) was founded in the interests of the new movement; and its collection, *The Newest Day*, gave a first survey of the new art and its chief authors.

The Second Phase.—The second main offensive, opened in 1914 with Walter Hasenclever's play *Der Sohn*, was held up at first by the War. The radical ideas of the new movement suffered under a rigorous government censorship. The *Aktion*, originally a "periodical for liberal politics and literature," became perforce for years a purely literary affair; the *Weisse Blätter*, of which René Schickele became editor in 1915, was issued outside Germany, in Zürich, where it served as a mouthpiece for young writers such as Johannes R. Becker, Albert Ehrenstein, Leonhard Frank, Rudolph Leonhard, Alfred Wolfenstein, Walter Hasenclever, Ludwig Rubiner. The more revolutionary ideas gained ground as the War dragged on, the more violently did the whole movement break through the dams, until the highest flood-mark was reached in 1918 and 1919. The breakthrough was signalled by a host of periodicals, usually shortlived, whose very titles flamed like beacons; and by new publishing firms. Besides the *Jüngster Tag* series, the *Neue Reihe* appeared, containing old and new names. From 1914 on, the breakthrough had visible effect on artistic forms. In lyrical poetry the change comes with J. R. Becker's *Verfall und Triumph* and August Stramm's *Gedichte*. The "analytic" drama of the immediate past gives way more and more to the new form of a "synthetic" series of pictures. Strindberg set the example. Originally lyrical and ecstatic, given to dramatic monologue—for monologue gives relief from the sober, practical methods or crude psychology of the preceding decades—the movement at the same time invaded prose-fiction. So, by the side of the new lyric and dramatic poets —Fritz von Unruh, Reinhard Goering, Paul Kornfeld—we find new novelists like Leonhard Frank, Gottfried Benn, Franz Kafka, Kasimir Edschmid, Alfred Döblin. The years 1919 and 192 mark the close of an old period and the beginning of a new on What real progress had been made was shown in the excellen anthologies and collections of this time. In the *Symphon* *jüngster Dichtung—Menschheitsdämmerung*, put together b Kurt Pinthus in 1920, the *Anthologie junger Lyrik—Verkünd* *gung*, issued by Rudolf Kayser in 1921; in Ludwig Rubiner collections of poems *Weltrevolution—Kameraden der Menschhe* (1919) and in the *Novellen an die Zeit—Die Entfaltung* issued b Max Krell in 1921—in all these works an effort is made to asse the real value of the new achievements. A periodical such a *Der Genius*, which attempted to be for the expressionist era wha *Pan* had been for the impressionist; such also as the two yea books of new creative and critical literature issued by Alfre Wolfenstein in 1919 and 1920 under the title of *Die Erhebung*— these were partly retrospective. Dramatic pictures like Alfre Brust's play *Die Schlacht der Heilande* or Arnolt Bronnen *Vatermord* already indicated new developments, as did Wo Przygode's series, *Die Dich*.[1]

In the period of naturalism, theory and criticism were th creative and directing forces; they created the novel of experienc and frank "realism." Now it is otherwise; theory does not dire the work of art, but develops with it. *Charon* poetry precede the theory of Charonism. Edschmid's famous discussions o poetic expressionism came after the early works which decide him. Kornfeld's studies of inspired man and psychological ma appeared after his *Verführung*. The order is only reversed i the eccentricities of the movement, in the purely intellectu experiments. Yet here, as everywhere, will and deed fertilis each other. The most illuminating of the early books dealin with the movement are really those which treat of it in paintin and sculpture; as Kandiusky's book on *Das Geistige in der Kuns* Wilhelm Worringer's *Beitrag zur Stylpsychologie, Abstraktion un* *Einfühlung* and his *Formprobleme der Gotik*. Bergson, with hi doctrine of creative development, takes the place of Taine. Sie mund Freud's teaching is greedily devoured; his psycho-analysi the first real investigation of the soul, replaces the old dogma tism. Others are influenced by one who stands at the opposit pole from Hiller and Rubiner—the Zionist Martin Buber, th champion of every kind of belief in the vitality of myth and th redeeming strength of the soul. Rudolph Steiner's anthropo sophic writings also have their effect. And if the new artist ask his hearer to rise to his level, to take a creative part in his wor yet two Austrian philosophers of the older generation, born i 1860—Alexius Meinong and Edmund Husserl—had alrea laid a scientific basis for these emotional demands in their *Unte* *suchungen zur Gegenstandstheorie und Psychologie*, in which the exploded the "Empiric bases of our knowledge," their *Ideen* *einer reinen Phänomenologie und phänomenologischen Philosoph* and their doctrine of pure "Wesensschau." Then between 19 and 1920 appeared the publications which summed up what ha gone before and laid down definite aims: Ludwig Rubiner's co lection of fiery appeals, *Der Mensch in der Mitte* and his *Doku* *mente der geistigen Weltwende*, known as *Die Gemeinschaft*, Ku Hiller's year-books of spiritual policy, *Das Ziel* and Kasimi Edschmid's voluminous collection *Tribüne der Kunst und Zei*

The New Lyric.—In the period of naturalism prose-fictio predominated, but in the decade 1910–20, the lyric. The dram is lyrical, and even the novel is steeped in lyricism; despite itsel the influence of the lyric gives it something of the ballad in thi decade. As every realist drama bore the marks of its derivatio from the story or sketch, so every drama of this period bears th marks of its lyrical origin, down to the very stage directions. Th lyric poem itself in this period is generally an endless flow melody; it is also characterised by a wealth of interjections; relieves its emotions by an excess of O's, Ah's and How's, sug gesting an elemental outburst of dark, shapeless, chaotic force

---

[1] Expressionism apparently began as a secret language for th initiated, but within a few years it had become the fashion, the cu rent jargon of the literary market. Its divine fire, its exaltation an ecstasy were made ludicrous by the "Dada" movement; the artis the prophet, the creator of values were succeeded by mounteban who denied all values.

t first calmer, more harmoniously restrained temperaments
elieved fervently in evolution without end, in a new art not
eeding to renounce a noble heritage. This faith inspires the
ork of Ernst Lissauer (b. 1882), Leo Sternberg (b. 1876) and
eorg Hadwiger. It is significant that these authors are closely
ound up with the ballad and the ballad-mind, that when the
Var affects them it does so as the fate of the German world,
erman humanity, as a German war—not as a World War, as
e murder of man's image as a whole.

But the thought that a new art can only be won at the price
a frightful world catastrophe, darkly foreshadowing itself in
rt, breaking in advance all moral laws before shaking the world
the past into chaos—this foreboding it is—shown in images,
notions, rhythms, not yet degraded into lyrics of war or revo-
tion—that gives the poems of George Haym (1887–1912),
eorg Trakl (1887–1914) or Ernst Stadler (1883–1914) their
eculiar position. These are as yet no agitators; they are still
ure poets, prophets; they were broken before the War began,
they broke in its first months. Only a happier star preserved
aul Zech (b. 1881) and Armin T. Wegner (b. 1886) from a
milar fate; they too might have been broken by the irreconcil-
ble antagonisms of their experience, pit and forest, country
nd town, had not a new consciousness of community preserved
em. It is this same feeling of community, or the longing for it,
at gives the analytic "brain poetry" of Hoddis, Lichtenstein,
oldt, Benn, Lotz and Klemm the strength and light which
ines through the verses of the *Aufbruch der Jugend*. The same
eling in the poems of Franz Werfel, who as regards form is by
means always a "new" lyricist, accounts for their effect on
whole young generation, which gives him secure significance by
king him for a model. This is the feeling, enhanced by war and
volution, which fills the verses of Alfred Wolfenstein (b. 1888)
d René Schickerle (b. 1883), till in the hymns of Johannes R.
ecker (b. 1891), the poet of Utopias, it rises to boiling-point
d evaporates. Yet it would be a mistake to suppose that this
eling of community, this creed of "Thou and One Another,"
the only element in the poetry of the time. There are lonely
ooders, like Else Lasker (b. 1876), Theodor Däubler (b. 1876),
bert Ehrenstein (b. 1886), whose poetry springs from quite
er sources. Herwarth Walden's *Sturm* united all lyric poets
o repudiate any continuity of thought as inartistic and wish
weld the lyric into a pure linguistic form of vowels and con-
nants, a pattern of "associated" sounds.

The New Drama.—German expressionist drama does not
eak quite such new ground as expressionist poetry. It has two
odels, Franz Wedekind and August Strindberg, and it rings
ntinual changes on their themes. In their works they present
new problems, and at the same time solve these problems in
exemplary manner, whether as spectacular or interpretative
matists. They create the new acting and the new staging.
indberg and Wedekind are accepted as masters by many
hout tradition who cherish a confessed or unavowed longing
moorings and firm anchorage. These are lonely bearers of the
ssage of community; the defeated who yet must seek to save
er the world or themselves; the godless who yearn after God;
es of impulse whose instincts are unsure; beast-men in the
of dark forces, brain-men who have experienced in their own
s the curse of a purely intellectual estimate of all life; those
essed by a sense of the meaninglessness of many a life, or of
life, who yet long to find a meaning. The votaries of this
ld, those who adore flesh and blood, live on Wedekind; those
he world beyond, who worship the spirit, live on Strindberg;
both alike are unredeemed victims following a way of the
ss. Whether calling themselves saints or penitents, they are
by a torment which drives them through "heaven and hell."
s no mere chance that these latter words are the title of an
ntially important work of this time, a play, by Paul Kornfeld.
ut besides Wedekind and Strindberg there is a third origi-
ng ancestor and an earlier—Georg Büchner (1813–1851),
creator of *Woyzek*, that drama which is nothing but a Way
e Cross, nothing but a view of the world through the soul of
pless martyr. There is hardly one expressionist drama without the Woyzek frame of mind, the Woyzek characterisation, the Woyzek life-blood. These outlines may suffice to show how inadequate is the term "expressionist dramatists;" how varied can be the world which an "expressionist" dramatist reflects. Halfway between the two periods stands Carl Sternheim (b. 1881). In his hatred of the bourgeois which inspired the comedies *Aus dem bürgerlichen Heldenleben* he is akin to Wedekind; but he despises the doctrine of brotherliness and love of mankind, he is dry and cold, crystal-clear, free from mist, a virtuoso of form, his every word plain and unmistakable. Georg Kaiser (b. 1878), the "cubist" of drama, is as true to form, but you cannot grasp him; the man is an enigma like each of his works.

They seem to come out of some other age than ours and to pass into yet another—creations of impassioned suffering or of pleasure in the "game of thinking," as Kaiser once termed his ideal of drama. What have Sternheim and Kaiser in common, beyond the joy in solid construction? Not even that connection exists between them and another pair, the poet of the blessed ego and him of the accursed ego, the poet of *Bettler* and the poet of *Himmel und Hölle*, Reinhardt Johannes Sorge (1891–1916), that pious disciple of Christianity; and Paul Kornfeld (b. 1889), the young apostle of an all-believing orientalism. Or what have these "philosophic politicians" in common with the real politicians, with Ludwig Rubiner (1888–1920) and Ernst Toller (b. 1893), the author of *Masse Mensch*, or with Reinhard Goering, author of *Seeschlacht* and *Scapa Flow*, or with Fritz von Unruh, the writer of *Louis Ferdinand* and *Ein Geschlecht*, whose whole work is inspired by the desire to show the symbolic meaning of the sorrows of mankind to-day in a myth of mankind future? The young humanity of Walter Hasenclever (b. 1890) revealed in his *Der Sohn*, what has it in common with the other young humanity of Hans Johst (b. 1890) in his *Der junge Mensch?* Or that other again of Anton Wildgans (b. 1881) in his *Dies Irae?* What is the link between the two artists from the sister realm of painting and sculpture, the terrified dreamer Oskar Kokoschka (b. 1886) and "Ernst Barlach" (b. 1870), that seeker after God? Or between legend-writers like Dietzenschmidt (b. 1893) on the one hand and Rolf Lauckner (b. 1887) or Alfred Brust (b. 1891) on the other? We see that expressionist drama, almost more even than the expressionist lyric, is the utterance of an age of confusion: it reflects the death-pangs of one world, the birth-pangs of another.

The New Prose-fiction.—The picture that we gain of expressionist prose-fiction is quieter. The reason is not far to seek; for if "the substance of the age"—all it "holds" of the past, present and future—is more clearly shown here than anywhere else, yet the novel seems alien to the "form of the age," the expressionist style. Expressionism is lyrical compulsion, dramatic impulsion, not epic propulsion. The longing of the age for the images of a new humanity and a new community offers many-sided satisfactions to the novelist. He is tempted to bring Utopias nearer our reach. But in conjuring up the picture of a future world, he forsakes to-day's world of chaos; out of its wreckage he makes a new world by new laws; but, above all, he sees one thing: that the spirit can create no world unless it begs Nature to assist it. Many a modern catchword is shattered by the restrictions of tale-telling art: among them phrases like "pure spirit" or "metaphysical space." There have been only isolated attempts to create pure "brain work." In fact, novelists like Gustav Sack, Kasimir Edschmid, Alfred Döblin, have proved, both by their work itself and by their own pronouncements on it, that they will have nothing to do with narrow-minded antagonism to nature. Certainly their work is no mere passive reflection of nature. Prose fiction of to-day requires scenic description, where life and its circumstances must be represented as in the historical or exotic novel; yet this is not now done at a leisurely length unbroken by action, but by a more concentrated method seizing on the decisive moments when significance springs out of circumstance.

Similarly, the outward and surrounding world is always being absorbed into the world within us; each man creates for himself a new outer world, which is nothing but his own soul projected into external form, the representation of all its impulses, the laying bare of its inmost secrets. The manner of narration, too, with its terse words and concise sentences, the accents of unrest and agitation—this is the very opposite of the old descriptive mode. The impression which all this gives is heightened by an avalanche of incidents. Events come thick and fast to match the hurrying giddy frivolity of life to-day, a whirling vortex chafing nerve and spirit. The long-starved appetite for material is glutted. We have a variegated cinema-world shown often by a cinematic method in novel-writing—jerky, abrupt, tempestuous, with flickering lights. We may pass by the hangers-on and imitators of the true expressionist movement.

The weary search of this age after a meaning in existence is tragically uttered in the works of the best novelists of Expressionism. Metaphysicians and believers like Max Brod (b. 1884), unbelievers like Gustav Sack (1885–1916) and Gottfried Benn (b. 1886), exhaust themselves in struggles of joy or despair. Kasimir Edschmid (b. 1890) flies to adventure for a firm foothold and plain idea; "Klabund" (Alfred Henschke, b. 1892) ceaselessly changes his phases; Leonhard Frank (b. 1882), author of *Der Mensch ist gut* (a collection of short stories), believes that he can find salvation in a renewed feeling of community. Another, Franz Kafka (d. 1924) sees that in this world there is no salvation, that all we can do is to gain a glimpse of the heaven of another world through the artistry of pure literature. Others again, as "Mynona" (Salomo Friedländer, b. 1871), construct a fabulous realm of new forces and seek to prove that nothing is more fantastical, more like a Utopia than nature. The work of Alfred Döblin (b. 1878) is inspired by the same feeling and leads him to the same conclusion in his romance of the future, *Berge Meere Giganten*, which describes titanic battles between mankind and nature.

The Reaction.—As indicated above, the wave of expressionism reached its height in 1920 and then suddenly broke altogether. After the boundless over-conceit which every revolution brings came a moment when the artist paused to reflect while the public was sobered. Will and deed, claim and achievement, promise and performance had been taken as one. In expressionism men had seen the revolt of the spirit against matter, of liberty against mechanical slavery, of creative force against the receptive mood and formal reason. All this was regarded as a vision of the future illuminating the background of a shattered past. But the course of the political revolution, in particular, showed that new humanity, after all, was subject to the original sin of all existence, the luckless children of a luckless age which lets no man be without devouring him again as a victim. Expressionism, in its latest phase, is usually the tortured outcry of the mangled victims of an age who yet believe themselves its saviours.

It is thus not surprising that literature once more seeks and finds contact again with powers and forces to which artistic teaching just before had denied any importance whether for substance or form. In our survey of the development of prose-fiction we have mentioned the return to nature. In literature, as in all art, there was talk of a "new reality," a "new objectivity," a new kind of literal naturalism. This new realism was termed "Magianism," to signify that it had borrowed essential characteristics from expressionism, and like it satisfied metaphysical needs. The name "Verism" means much the same. Hand in hand with a new reverence for nature goes a new regard for science, even for technique where it is creative. A novelist like Josef Ponten (b. 1883) is struggling, consciously or unconsciously, towards a marriage of science and art. The new task appears to be to spiritualise, elevate, to mythify everything belonging to science and mechanism, and all the characteristic factors of civilisation in our time. In the same way re-arises respect for tradition. The consciousness of a culture, nourished by all ages and peoples, comes to its own again; it finds its highest expression in the writings of Albrecht Schaeffer (b. 1885) whose comprehensive three-volume *Helianth* (1920) is one of those romances of education peculiarly significant in German literature, while his *Parzival* (1920) is one of the equally typical poems of deliverance. But another part of German literature took new blood
from new spiritual experience. The all-embracing internatio
love which poets and playwrights, especially of Jewish orig
had proclaimed with particular fervour, was ruthlessly destroy
after the War by the events of foreign and domestic polit
Then writers began again to think of the elemental forces of r
and nationality, out of which the super-national, super-tempo
always sprang. Finally, a German neo-Catholic school of lett
is undeniably growing up (R. J. Sorge, 1891–1916; Dietz
schmidt, b. 1893; Leo Weismantel, b. 1888).

This renewal of substance is accompanied by a revision
form. Here, too, faith in the tranquillising, uniting forces te
to gain the upper hand over faith in revolutionary and disrupt
forces. Idiom is becoming fixed; dramatic and epic struct
more coherent; the form of the lyric more crystallised. In c
connection with the new thinking there is a fresh appreciatio
workmanship, of ability, of technical mastery—things laug
at by a yesterday which had forgotten the "how" in its conc
with the "what." The development of the novel and the dra
show most clearly why the art of the most recent years is tend
towards a compromise between naturalism and impression
on the one side, expressionism on the other. How varied ca
the forms of this compromise is shown by the work of novel
like Albrecht Schaeffer, Josef Ponten, Wilhelm Lehmann
1882), Rudolf G. Binding (b. 1867), Otto Flake (b. 1882), Fr
Thiess (b. 1890), Arnold Ulitz (b. 1888). A good survey of
modern art of prose-fiction may be obtained from the "Libra
of modern stories *Der Falke*, which has been appearing si
1923. In drama the tendency to get lost in Utopian ideals,
the vagueness which often accompanied it, has given way
method that comes nearer to earth with more sureness and f
ness of outline. Where the dramas of Arnold Bronnen (b. 18
Bertolt Brecht (b. 1894), Max Mohr (b. 1891), Otto Brües
1897), Friedrich Griese (b. 1890), Rolf Lauckner (b. 1887), H
W. Fischer (b. 1876), Paul Gurk (b. 1880) are in advance of
dramas of the pure expressionists is in their genuine feeling
the theatre itself. In lyric poetry the new purpose and the
faculty are seen in the work of Oskar Loerke (b. 1889), Fried
Schnack (b. 1888), Anton Schnack (b. 1892), Fritz Walter
choff (b. 1896), Ina Seidel (b. 1885 and Ludwig Strauss (b. 18
The word *World-Inwardness* (*Weltinnigkeit*), chosen by
Seidel as the title of a volume of poems, well defines the spiri
the new poetry.

GERMAN OFFENSIVE (March–June 1918).—After the
of the battle of the Marne, in Sept. 1914, and the abor
operations which followed it on the Aisne and in Flanders,
German higher command changed the idea which unde
their strategy. In Aug. 1914 their main blow was to be d
against their strongest adversary, and France was to be crus
before Russia could develop her strength. The deci
victory of Tannenberg had, however, opened their eyes to
rottenness of the Russian Army, and from Oct. 1914 onwa
until March 1918 the aim of the German General staff wa
hit at weakness in order to isolate their strongest advers
namely, the French. The series of battles carried out du
the first six months of 1916 in the neighbourhood of Verdun
no exception to this crucial strategical idea, since its aim
defensive—that is, its intentions was not to gain a dec
victory in the West, but to dislocate the impending French
British operations and gain time wherein to defeat Russia.

The campaign in Russia, however, dragged on, the same
ditions appearing as in 1812—climate, lack of communicat
and distance rendering every tactical victory abortive. To m
up for this delay, in the autumn of 1916 Rumania is selected as
weakest point of attack, and is overrun. A year later Ital
selected, and the result is the Italian débâcle at Capore

nultaneously Russia, to all intents and purposes, disappears as ıostile power, so that by the end of 1917 Germany could once ıin turn to the task she had abandoned in the autumn of 1914, mely, the defeat of the French now so strongly supported by British Empire.

The political situation which faced the Imperial Govt. in rlin was one which demanded a rapid conclusion of the War. t only had unrestricted submarine warfare failed to produce attrition expected, but the stranglehold of the British vy was daily reducing the morale of the German people. Of allies, Turkey was the only one who seemed to be in earnest. lgaria's interest in the War was waning, and Austria and ıngary were worn out, having lost nearly 2,000,000 men in soners alone. These conditions demanded immediate and isive action if the War was to be won before America could elop her strength.

Whilst the Central Powers had been striking at weakness, eat Britain had been engaged in a similar strategy. The lemate which had been established on the Western Front, and abortive campaigns which had followed this stalemate, had ced her into seeking a line of least resistance by means of her vy, with the result that, by the end of 1917, a serious dispersion fighting force had taken place, extensive operations being in ogress in Palestine, Macedonia and Mesopotamia, without ınting minor campaigns in Africa. Further, the British ces in France had been bled white, the Arras, Messines, Ypres d Cambrai battles having alone accounted for 650,000 men. e general situation was that whilst France had been recover- her strength the British forces had grown steadily weaker. e offensive initiated by Germany on the Western Front in arch 1918 is here described as three main battles, namely, St. Quentin; II. The Lys; and III. Soissons-Reims.

I. THE BATTLE OF ST. QUENTIN

General Ludendorff, who by now had become the directing nius of the German war brain, was faced by the problem of ere the decisive blow should be struck, and determining strike at weakness he selected the British front for the de- ive attack. This front may be divided into three sectors Flanders, the Bruay area and the country southeast of it tween Cambrai and St. Quentin. The first of these was viously unsuited for offensive action of a decisive nature, as British operations of 1917 had clearly shown. The second ered an opportunity of striking at the French coal supply, a al factor, but the front of attack was restricted and difficult. e third included good offensive country, as it consisted of en field land and led to the valley of the Oise, a natural avenue ding to Paris.

Ludendorff's Opinion.—Though Ludendorff writes that actics had to be considered before purely strategical objects ich it is futile to pursue unless tactical success is possible," uccessful attack in this direction would not only isolate the itish forces by severing their connection with the French, but, if shed towards Paris, would jeopardise the line of communi- tions of all the French forces situated east of Soissons. The ategical possibilities of such an attack are therefore closely nparable with those of the original plan of campaign worked t by Schlieffen long before the War. To deliver this blow dendorff proposed to muster every available man and gun d further to accentuate the force of numbers by surprise, for tank attack at Cambrai and Hutier's gas attack at Riga had monstrated the overwhelming power of an unexpected assault. saw clearly that the forthcoming struggle would be no light e, and in an audience at Homburg with the Kaiser and the ancellor he said:—

'The battle in the West is the greatest military task that s ever been imposed upon an army. . . . It cannot be success- ly accomplished unless the authorities who conduct the War relieved of all intolerable shackles, unless the very last man employed in the decisive conflict, and is animated, not only love for his emperor and his native land, but by confidence in strength of the military leadership and the greatness of our country. These spiritual forces must not be underestimated, they are the foundations of the greatest deeds. . . . We must not imagine that this offensive will be like those in Galicia or Italy; it will be an immense struggle that will begin at one point, continue at another, and take a long time; it is difficult, but it will be victorious."

The Opposing Forces.—Between Nov. 1 1917 and March 21 1918 the German divisions on the Western Front were increased from 146 to 192, troops being withdrawn from Russia, Galicia, Italy and the East. By these means the German armies in the West were reinforced by no less than 18,492 officers and 553,794 other ranks. Finally it was decided to make available 62 divisions and 1,706 batteries for the main attack. These troops were carefully trained for mobile warfare on any sector of the French and British fronts, the greatest secrecy being maintained as to the actual area of attack, which extended from the south of Lens in the north to a little south of La Fère.

On the side of the Allies, except for a few miles in the north, this front was held by the III. and V. British Armies respectively, commanded by Sir Julian Byng and Sir Hubert Gough. The front of the III. Army extended from just south of the village of Gavrelle to half a mile north of Gouzeaucourt (26½ m.), and on March 21 was held by 10 divisions in line and seven in reserve. The V. Army front (42 m.) ran from the right of the III. Army to the village of Barisis, a little south of the river Oise, between the forests of Coucy and St. Gobain. On this extended front there were 11 divisions in line and three in reserve.

German Plans.—The plans of attack were issued by the Supreme Command on Jan. 24 1918. The attack was to be carried out by four armies:—

(*a*) XVII. Army (Below), comprising 17 divisions, was to attack on the frontage Gavrelle-Moeuvres.

(*b*) II. Army (Marwitz), comprising 18 divisions, was to attack from Moeuvres to Pontru (north of St. Quentin).

(*c*) XVIII. Army (Hutier), comprising 24 divisions, was to attack from Pontru to Vendeuil (south of St. Quentin).

(*d*) VII. Army (Gayl) was to demonstrate with three divisions against La Fère.

The various attacks were named as follows: XVII. Army, left wing attack "Mars" (south of Bapaume), right wing "Michael I." (north of Bapaume); II. Army, "Michael II.," to the north of the Omignon brook; XVIII. Army, "Michael III.," north and south of St. Quentin; VII. Army, "Archangel," south of the river Oise. The "Michael" attacks were to be delivered on the first day of the battle, followed a day or two later by the "Mars" and "Archangel" attacks. The object of the "Michael" attacks was to penetrate the enemy's front, and then, supported by the "Mars" attack, both were to push on through Peronne-Arras and Peronne-La Fère.

To bewilder the enemy as to the frontage selected for the main attack, subsidiary operations were prepared all along the Allied front, at Ypres-La Bassée, Reims, the Argonne and in Champagne. From March 14 onwards the crown prince was to bombard the enemy's headquarters on his front and make a show of bringing up reinforcements, and Gallwitz was to carry out an attack on Verdun up to the point of engaging his infantry.

Preparations for the Attack.—The forming up for deployment of the attacking armies was begun on March 10, the divisions being organised in groups normally in a depth of three lines. The first or assault line was made the strongest, and was moved close up to the front on March 20. The second line of divisions was some three to five km. in rear, and the third seven to ten km. behind the second line; this third line was to be held in reserve under the higher command, and was only to be used as the operations developed.

On March 20 all was in readiness for the attack, which was to be preceded by a three hours' hurricane bombardment in which gas was to be employed extensively by the artillery and minenwerfers. By this means it was hoped to paralyse the enemy. On the 20th, however, the wind was at first unfavourable, but by midday conditions had sufficiently improved to permit of the bombardment taking place. It was opened at 3:30 A.M. on the 21st, the Allied batteries being first gassed.

The infantry attack did not, however, take place until 9:40 A.M., when a general move forward was made under a creeping barrage supplemented by low-flying aeroplanes.

FRENCH FRONT LINE PRIOR TO ATTACK ON 9TH OF JUNE
FRENCH FRONT LINE, MARCH 24TH

March 21.—The attack of the XVII. Army was met by strong opposition, which was accentuated by the fact that the infantry were unable to keep up with the barrage. At Vaulx-Vraucourt and Doignies strong counter-attacks were launched against them, and by nightfall the German divisions had to be reinforced by second line troops. The II. Army advanced to the line Gouzeaucourt-Epéhy-Templeux-Le Verguier, a fierce struggle taking place at Epéhy, which throughout the day remained in British hands. The XVIII. Army was more successful. Its right captured Holnon and Holnon wood; its centre got to Sa and Dallon, and its left captured a part of Essigny and Bena but was checked a little west of Vendeuil.

On the 22nd the attack was continued with vigour. T XVIII. Army was reinforced and was ordered to advance Tertry to facilitate the operations of the II. Army, which ha outrun its artillery support. The brunt of the fighting fell o the XVII. Army, which attacked the British second line o defence again and again, only to be met by vigorous counter attacks supported by tanks. Towards the close of the day, bu only after having been reinforced by third line units, it succeeded in capturing Croiselles, Vaulx-Vraucourt, Morchies an

Hermies. The II. Army pushed forward to Fins-Longavesnes-Marquaix-Caulaincourt, and the XVIII. Army captured Fluquières and crossed the Crozat Canal between Jussy and Terguier.

From the positions held on the 22nd the XVII. Army advanced n Bapaume and captured Driencourt, St. Léger, Beaumetz and Lebucquière. The II. Army reached the line Neuville-Bouchavesnes-Brie, and the XVIII. Army crossed the Somme at Bethencourt and captured the town Ham.

Between the 24th and the 26th the advance was steadily ontinued, and on these three days the German front was advanced to the following lines respectively: (*a*) 24th, Chauny—Guiscard—Morchain—west of Peronne—Curlu—Fremincourt—ampoux; (*b*) 25th, Noyon—east of Roye—east of Chaulnes—Frise—Beaucourt—Boiry; (*c*) 26th, west of Noyon—Le Quesoy—Framerville—Bray—east of Albert—Pusieux—Boiry.

Ludendorff's Second Plan.—The first great stage of the attack ow drew to a close, for not only had British resistance stiffened, but the difficulties of supplying the advancing armies over the ld Somme battlefield were so great that it was found impossible o maintain the leading troops. The result of this was that on he evening of the 26th Ludendorff determined on a change in lan. He now decided to separate the British and French forces by wheeling the II. and XVIII. Armies against the latter. The difficulty of supply was, however, too great for this change f front to succeed, consequently on the 27th Ludendorff made further change. He ordered the XVII. Army to close down he attack, and the XVIII. Army and left of the II. Army to ttack the French between the Oise and the Somme. By March 0 this attack advanced the huge pocket which had been found in the Allied front from a little south of Noyon to west of Montdidier, thence through Haricourt and Hangard to the omme north of Hamel.

Between this date and April 4, further attacks, mostly of a minor nature, extended the pocket from west of Montdidier to ast of Rouvrel, thence through Hangard east of Villers-Bretonneux to east of Corbie on the Somme. On April 4 the reat battle to all intents and purposes came to an end. The initial success had been great; since March 21 from a base of 4 m. a penetration of no less than 38 m. had been effected; the round lost in 1916 and abandoned in 1917 had been more than made good, and enormous booty as well as 90,000 prisoners and ,200 guns had been captured. The British Armies had been seriously defeated, and 20 French divisions had been drawn into the battle; yet, in spite of the fact that 90 German divisions ad been engaged, neither the transition to a war of movement or the separation of the British and French forces had been chieved.

Causes of German Success.—The initial successes of this reat battle were due to the length of front attacked; the comarative weakness of the British forces when compared with the ngth of line held by them; the rawness of these forces due to the losses suffered during 1917 which had been made good by astily trained troops; and the surprise of the attack itself, for though the British higher command suspected an attack on the onts of the V. and III. Armies, when the attack was launched many of the reserve divisions were still in the Flanders area. The ilure of the battle was due to well ascertainable causes, the wo most important being the comparative narrowness of the ont when compared with the depth of penetration required in order to obtain a decisive result, and the insuperable difficulty of keeping an advancing front of many divisions supplied. The German front of attack on March 21 stretched from three m. south of a Fère to three m. south of Lens, a distance of about 74 m. and by April 4 the depth of the penetration effected was some 38 miles.

A study of the various pockets formed by frontal attacks roughout the War will show that the depth of penetration was approximately half the length of the front attacked. Conquently, if it was necessary to reach Abbeville, which is about m. from the original German front, in order to effect a separaon of the British and French forces, so as to enable a change front on the line Abbeville-Soissons being made towards Paris, the initial front of attack should have been as least 120 m. in width. Though the German forces were insufficient to attack on such a frontage, had they been sufficient the second factor, namely, difficulty of supply, would in all probability have wrecked their plan.

We thus see that any attempt on the part of the Germans to win the War by an immense frontal attack before the Americans could develop their strength was, as long as the Allies resisted stubbornly, virtually an impossible operation. This by April 4 was realised by the German higher command, for the battle on the Amiens-Noyon front was closed down, save for minor operations south of La Fère, and other fronts of attack were sought, namely, those west of Lille, south of Laon and north of Compiègne, which were attacked on April 9, May 27 and June 9 respectively.

(J. F. C. F.)

II. THE BATTLE OF THE LYS

In the general scheme of the great German offensive of 1918, the idea of breaking through the British-Portuguese front in French Flanders was considered by the German High Command. Although this scheme became secondary to the great offensive further south, the preparations for it were carried out, firstly in order to mislead the British and Allied headquarters, and secondly that the Germans might be able to revert quickly to it in case the Somme offensive should come to a standstill.

When on March 30 it became obvious that no further progress was possible in the southern battle area, the German Supreme Command decided to put into effect the Flanders attack, the preparations for which were nearly complete. Although they did not anticipate that they would be able to force a decision in this area, there were certain definite advantages to be obtained from a successful blow in the direction of St. Omer-Hazebrouck and the local situation favoured, in their opinion, the prospect of success. This was to be the second blow struck against the British Army, a great proportion of which had already been employed on the southern front. The main weight of the initial blow was to fall on the Portuguese division, known to be less experienced and of less fighting value than British formations.

The abnormally dry weather gave good grounds for hope that the Lys valley would be practicable, a state of affairs which was not the case till much later in the spring in a normal year. The only lateral lines of communication in this sector of the British zone, other than the coast railway, ran through St. Pol-Lillers-Hazebrouck, and if the use of this could be denied to the British, problems of supply and reinforcement would be immeasurably complicated. It was above all important, in the view of the German Supreme Command, to retain the initiative, and to strike a second blow before the French could organise a counter-attack against the somewhat vulnerable southern flank of the salient which had been created by the success of the Somme offensive.

Plan of Attack.—The general plan of attack was that the main blow should be struck by Quast's VI. Army on the front between Armentières and the La Bassée Canal, in the direction of Hazebrouck. If the VI. Army's attack met with sufficient success, the IV. Army under Arnim was to advance north of Armentières, which was to be made to fall by envelopment, with the eventual object of securing the heights stretching from Kemmel to Mt. des Cats, south of the Ypres-Poperinghe road. If this were achieved the British and Belgian positions in the Ypres salient and on the Yser would be threatened from the rear. The extension of the attack southwards was a secondary consideration, but it was hoped that at least the destruction of the important mining area south of Bethune might be achieved.

Forces Engaged.—The forces available for the operation of the German VI. Army were four corps, from north to south, the Bavarian II. and German XIX., LV. and IV., to which were allotted nine divisions in the first line and five in corps reserve. Three more divisions were retained in army reserve. The sub-

sidiary attack of the German IV. Army was to be delivered by the X. and XVIII. Res. Corps, with three divisions in the first and one in the second line.

The initial blow fell on the left of the I. and right of the II. British Armies, under Sir Henry Horne and Sir Herbert Plumer, the point of junction between which was, on April 9, the Lys, east of Armentières. The XI. Corps (British 55th and Portuguese 2nd Divs.) and the XV. Corps (40th and 34th Divs.) held the front from the La Bassée Canal to the Lys, while the IX. Corps (25th, 19th and 9th Divs.) continued the line from the Lys to the Ypres-Comines Canal. With the exception of the 55th, all these British divisions had already taken part in the southern battle and had been rapidly made up with reinfor ments from home. Three more battle-worn divisions were corps reserve.

The Battle Opens.—At about 4 A.M. on April 9 the battle oper with an intense bombardment of the whole front from Lens Armentières, with both gas and high-explosive shell. The fr trenches were subjected to a rain of high explosive, while batt positions, cross roads, headquarters and railheads far in r were treated with both gas and high explosive. Armentiè itself and the British position south of the La Bassée Canal w deluged with mustard gas. The foggy morning made obser tion difficult, and, according to German accounts, the count mbardment was ineffective. Between 8 and 9 A.M. nine Ger- an divisions, with ample reserves at hand, were launched ainst the two British and one Portuguese divisions. In the ntre the weight of the attack of the German XIX. and LV. rps overwhelmed the Portuguese 2nd Div., and both corps vanced steadily towards their objectives. The right of the avarian II. Corps was held firmly by the 40th Div., but the t of the Bavarians succeeded in advancing past the right flank that division. On the British right the 55th Div. held stoutly to Givenchy and north of that place withdrew slowly from e outpost position to the main line of resistance which ran just st of Festubert.

All available British reserves were hurried up; the reserve igade of the 55th Div. was employed to form a defensive flank cing north, from Festubert, south of Le Touret to the Lawe. e 11th Cyclist Bn. and King Edward's Horse were rushed up Lacouture, Vieille-Chapelle and Huit Maisons and by their roic resistance effectually prevented any extension of the break rough to the south. The 51st and 50th Divs. were moved up m the back areas to the river Lawe and the neighbourhood Estaires respectively. Meanwhile the 55th Div. continued to ld its position at Givenchy and Festubert throughout the day d in counter-attacks against elements of the enemy, which had netrated into their position, captured over 750 prisoners. he magnificent fight put up by this division completely broke e attack of the Prussian IV. Corps.

On the northern flank of the battle, the Bavarian II. Corps suc- eeded eventually in occupying the forward posts of the right ttalion of the 40th Div., and gradually worked their way north- ards. By 10:15 A.M. on April 9 the Bavarians were in Rouge De out, some 2,000 yd. in rear of the headquarters of the right ttalion of the 40th Div., which was still holding out in Petillon. y noon the division was forced back by pressure in front and nk to a position facing south from Bois Grenier through Fleur- ix to Sailly-sur-Lys. Owing to the rapid advance of the Ger- an centre the 50th Div. was unable to gain touch with the 40th, e right flank of which withdrew across the Lys at Bac St. Maur rly in the afternoon. The remainder of this division, reinforced y troops of the 34th Div., successfully maintained their line vering the approaches to Erquinghem and Armentières from e south, till the evening.

The Saxon XIX. Corps had rapidly followed up the right of e 40th Div. and about 3 P.M. succeeded in passing small bodies troops across the Lys at Bac St. Maur. During the remainder the afternoon and evening the strength of the German force orth of the river steadily increased, and they eventually reached roix du Bac, where they were successfully counter-attacked nd driven back by a brigade of the 25th Division. During the ight the Germans established themselves firmly on the north ank, in the gap between the 40th and 50th British Divisions.

Renewal of the Attack.—On April 10 the attacks were renewed ll along the line. Practically no progress was made by the IV. orps on the left. It was only just before nightfall that the LV. orps succeeded in gaining a footing on the west bank of the awe between Lestrem and Vieille-Chapelle, and at Lestrem it- elf. At Estaires the 50th Div. defended itself with great gal- ntry and inflicted very heavy casualties on the enemy in the treet fighting which continued all day. It was only at nightfall hat this division was forced to withdraw to a prepared position orth and west of the town. East of Estaires the German Corps, hich had now got up artillery in support of its infantry and achine guns, pushed back the thin British line to a position orth of Steenwerck, where the arrival of reinforcements for a ime effectually held up the German advance.

Meanwhile, after an intense preliminary bombardment of he British positions between Frélinghien and Hill 60 north of he Ypres-Comines Canal, the German IV. Army about 5:30 .M. attacked the British VIII. Corps. The outposts of the 25th nd 19th Divs. were driven in and under cover of mist the Ger- an X. and XVIII. Res. Corps worked their way up the valleys f the Warnave and Douve rivers on the flanks of the British ositions in Ploegsteert Wood and Messines. By midday the village of Ploegsteert, the southeast corner of the wood and Messines had been captured. During the afternoon the German attack succeeded in capturing the outpost position as far north as the Ypres-Comines Canal, but was held up on the crest of the Wytschaete Ridge and in front of Hollebeke by the 9th Division. The South African brigade of the same division retook Messines during the afternoon. This further success of the Germans, combined with the progress made by the right flank of the German VI. Army, gravely imperilled the situation of the 34th Div. which was holding the original line east of Armentières and had not been attacked. A withdrawal to the north bank of the Lys was therefore decided on, and was completed by 9:30 P.M. when the Lys bridges were destroyed.

On April 11 the attack was continued. The German IV. Corps again failed to make any progress between Givenchy and the Lawe river. North of Locon the British 51st and 50th Divs., weakened by continuous fighting, were slowly pushed back by the German LV. and XIX. Corps. The British divisions fought with the greatest gallantry and inflicted very heavy casualties, but bodies of German infantry worked their way through gaps in the attenuated line and by nightfall they had reached Neuf-Berquin and were in occupation of Merville. Further east progress was checked by a counter-attack of the 31st Div., which had arrived from the southern battlefield, but the Bavarian II. Corps pushed forward through Nieppe to Steenwerck. Slight progress was made by the German IV. Army between Nieppe and Messines.

Renewed Attacks.—During April 12 the arrival of reinforcements, mostly from the southern battle front, began to have its effect. The right flank of the British still held firm, but the German LV. Corps, attacking before dawn in the mist, broke through the left centre of the 51st Div., and reached Pacaut and Riez du Vinage, where their progress was checked by two batteries of artillery. The British 3rd Div. had come into action about Locon, which village was lost to the German LV. Corps, but the German advance was checked and their troops suffered heavy casualties. The right flank of the same German Corps was checked in Calonne by the 61st Div., which, like the 3rd, had arrived from the Somme battle area.

Meantime the Bavarian II. and German XIX. Corps attacked in great strength between Vieux Berquin and Steenwerck. In spite of the gallant defence put up by the 29th and 31st Divs. they succeeded in occupying Doulieu and La Becque, forming a gap southwest of Bailleul, which enabled the Germans to seize the villages of Outtersteene and Merris. This gap was eventually blocked by a brigade of the 33rd Div. reinforced by a party of cyclists, a pioneer battalion and by every available man from the local schools and reinforcement camps. Further to the left the 25th, 34th and 49th Divs. maintained their positions against all attacks. During April 12 headquarters of Prince Rupert's group of armies issued orders for the continuance of the attack by the inner wings of the two armies, with the dual objectives of Hazebrouck and the range of hills north of Bailleul. The VI. Army was also to prepare to continue the pressure of their left wing towards Bethune. On April 13 the German attacks north of the Lys were continued with great vigour. On the left, elements of the LV. Corps, which had penetrated into the outskirts of the Nieppe Forest, were driven back by the British 5th Div., which, advancing by two roads south of and through the forest, soon established themselves on a firm line clear of the woods, and finally checked the German advance in this area.

The German XIX. Corps continued to attack the 29th and 31st British Divs., now greatly diminished in strength by continuous fighting, but these formations, reinforced by the 4th Guards Bde., held on with the greatest heroism to their extended lines of nearly 10,000 yards. Except at Vieux Berquin, which was captured by the Germans, who brought up guns to point blank range, those divisions carried out their instructions to hold their positions at all costs and cover the detrainment of the Australian 1st Division. The arrival of the Australians in the evening definitely closed the approach to Hazebrouck. Further northeast a succession of heavy attacks was driven off by the 33rd and 34th Divs. about Meteren and La Creche. In the early morning the German 36th Res. Div. penetrated with heavy loss into Neuve Église, but before noon they were driven out by the British 33rd and 49th Divisions.

Early on the morning of April 14 the British troops withdrew without interference to a new line in front of the Ravelsburg heights between Bailleul and Neuve Église. The latter village, after intense fighting all day, was finally captured by the Germans by midnight on the 14th. Elsewhere all attacks were repulsed, and the British 4th Div., coming up east of Robecq, between the 61st and 3rd Divs., recaptured Riez Du Vinage with a number of prisoners. On April 15 the German attacks were renewed. By this time their troops had been reinforced by the Guard Res. Corps on the left wing of the IV. Army. The IX. Res. Corps had come in on the right of the IV. Corps, and the Bavarian III. Corps had replaced the Bavarian II. Corps. Heavy attacks developed during the day culminated in the capture of Bailleul and the Ravelsburg Ridge.

British Withdrawal.—On the night of April 15–16 a withdrawal of the British troops from the Ypres salient to a line east of Ypres through St. Julien and along the Westhoek and Wytschaete Ridges was completed without interference. This move had been commenced on the night of the 12–13 by direction of British G.H.Q. in order to set free additional troops, and to forestall any plans the Germans might be entertaining for the extension of the battle front to the north. The withdrawal was well timed, as the Germans were preparing an offensive from the Houthulst Forest, and the preparations were almost complete when the British withdrawal took place.

On April 16 strong local attacks were made at various points on the Metheren-Wytschaete front, all of which were repulsed by the 25th, 34th and 49th Divs., except on the extreme flanks, where both villages, after intense fighting, eventually fell into German hands. On the following day determined efforts to take Mt. Kemmel and to advance on the Meteren-Merris front were repulsed, and the Belgian Army achieved a notable success in defeating a powerful assault against their right flank about the Ypres-Staden railway, in which they captured over 700 prisoners.

Meantime the Germans had been preparing to renew the attack on the British right flank, and on the 18th, after a very intense bombardment, the IV. and IX. Res. Corps advanced to the assault of the British positions about Givenchy-Festubert and Mt. Bernenchon-Hinges. On the British right they penetrated at certain points, but were thrown back by the 1st Div. which had relieved the 55th. Everywhere else they failed to obtain even an initial success, and were driven back with great loss by the 4th and 61st Divisions. For nearly a week the battle died down. On the British right minor operations were successfully undertaken to improve the position of the 4th and 61st Divs., northeast of Robecq, which resulted in the capture of numerous prisoners. In the left centre of the British front French troops, which had been brought up from the south, relieved some of the wearied British divisions, and by the morning of the 21st had taken over the sector between Metheren and Spanbroekmolen.

New German Plans.—During this pause the German Higher Command readjusted their plans. On the 18th the Army Group suggested that the main operations should be abandoned, and it was finally decided on the 20th that further operations should be limited to the capture of Mt. Kemmel on the north, and the villages of Givenchy and Festubert on the south. No success whatever was obtained on the southern flank, but the attacks about Mt. Kemmel led to further bitter fighting.

At 3:30 A.M. on April 25 an intense bombardment was opened on the French and British positions extending from Bailleul to the Ypres-Comines Canal. The main object of the attack was the capture of Kemmel Hill by direct assault on the French, combined with an attack on the British right south of Wytschaete, intended to separate it from the French. The attack was entrusted to the XVIII. Res., Alpine and X. Res. Corps, to which were allotted nine divisions, five of which were fresh. Between 6 and 7 A.M. the German infantry advanced, supported by large numbers of squadrons of battle planes and bombers. After intense fighting they succeeded by 10 A.M. in wresting Kemmel Hill and village from the French, detachments of whom, however, though surrounded, held out till late in the day. The weight of the initial attack on the British front fell on the 9th Div., who inflicted very heavy casualties on their enemy but by midday were forced back to Vierstraat. Further north the 21st Div., after a gallant resistance, was in the afternoon compelled to withdraw to a line Hill 60-Vormezeele. On April 26 the attack was renewed, and many counter-attacks were carried out both by British and French troops, the latter recapturing Locre.

On April 27 and 28 local fighting continued without substantial alteration in the situation. During the night of April 26–27 the salient east of Ypres was further reduced by a withdrawal without interference to the line Pilkem-Zillebeke-Lake-Voormezeele.

Final Attack.—The German final effort took place on April 29. The action started with a bombardment of exceptional intensity at 3:10 A.M. At 5 A.M. powerful attacks commenced against the French and British troops from west of Dranoutre to Voormezeele. After very heavy fighting the Germans gained a temporary success north of Locre, but were driven back by the French troops holding the sector. On the British front the positions held by the 21st, 49th and 25th Divs. were again and again attacked by German infantry, which advanced with great courage in massed formation. The assaulting troops suffered the heaviest losses, but their valour was of no avail. The British artillery and infantry fought with magnificent bravery and this final German effort was repulsed with practically no loss of ground.

Results of the Battle.—Thus ended the battle of the Lys. The second great German offensive had succeeded in penetrating the British front on a front of about 20 m. to an extreme depth of about 12 miles. A large number of towns and villages had been taken and nearly 30,000 Allied prisoners and 450 guns had been captured. But the attack had failed to gain its main objects. The lateral railway communication between St. Pol and Hazebrouck was still intact, the mining area south of Bethune was safe. Except for the detached hill of Kemmel, the high ground dominating the Poperinghe-Ypres road still remained in Allied hands. A pronounced salient had been formed in the German front which was to cost them dear in the succeeding months. On the other hand, the British had been forced to abandon the almost equally pronounced salient east of Ypres, and with it all the ground which had been gained at so great a cost in the battle of Passchendaele the previous year. The losses on both sides had been very heavy. To achieve these results the Germans had employed 42 divisions, of which 33 were fresh; 25 British divisions were employed, of which only eight had not been engaged in the battle of the Somme.

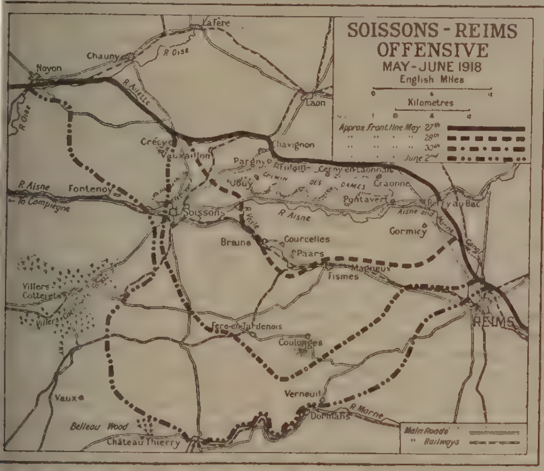
III. THE BATTLE OF SOISSONS-REIMS

After the relative failure of the German offensives of March and April it was incumbent upon the Germans, if they wished to preserve the initiative, to deliver another powerful blow without delay. The choice of the front of attack and the battle-ground fell on the oft-contested chain of heights between the Ailette and the Aisne, the Chemin-des-Dames.

Dispositions for the German Attack.—The German Supreme Command had decided to attack with the VII. and I. armies from the district southwestward of Laon—southwards of Berry-au-Bac in the direction Soissons-Fismes-Reims. If this attack proceeded favourably it was to be prolonged on the right over the Ailette to the Oise and on the left as far as Reims. Simultaneously an attack by the XVIII. Army was to be prepared westwards of the Oise with its centre of gravity in the direction

Compiègne. The German Supreme Command hoped that the h southward would succeed in reaching the neighbourhood of ssons and Fismes, and by this means attract strong forces n Flanders, so that it might be possible to continue the attack re according to plan. The army group under the Crown Prince pprecht was to remain purely on the defensive. On this front, on other sections of the Western Front where attack was not nded, feigned preparations for attack were to be made.

'reparations began about the middle of May. The VII. Army ler Böhm was charged with the main attack across the Chem- les-Dames, the I. Army under Below with the neighbouring ack on the left, and the XVIII. Army under Hutier with the ack in the direction of Compiègne. The right wing of the main ack, the LIV. Corps and the VIII. Res. Corps, had the task of hing forward in a southwesterly direction on both sides of ssons. The XXV. Res. Corps was to make its way on both es of Cerny-en-Laonnais direct towards Braisne, and on the t to take as much country as possible towards the south; the Res. Corps was to attack the " Winterberg " (*i.e.*, the height the eastern end of the Chemin-des-Dames; immediately north Craonne) with the main force and advance farther in the eral direction of Fismes; in concert with this on the left the V. Corps was to occupy with its left wing the river bend north Berry-au-Bac. Of the I. Army at first only one corps, ad- ncing simultaneously with the VII. Army, was to throw the posing forces over the Aisne-Marne canal. The corps was to vide itself with bridgeheads in order to take the heights of rmicy if the attack of the VII. Army proceeded favourably. urther attack to the right of the main attack was prepared by VII. Corps of the VII. Army, which was to push forward over Ailette, making its way in a southwesterly direction towards Oise. The number of divisions taking part in the attack was 41.



For success there were two essentials: the first, surprise; and second, effective artillery preparation. Most elaborate and rough precautions were taken to secure secrecy. As regards illery preparation the ascent of the steep slopes on the heights the Chemin-des-Dames was only possible if the Germans uld succeed in silencing the bulk of the opposing guns. All istration was to be abandoned in order to surprise the enemy much as possible. The first aim was to be a thorough gassing he Allied position right down into the Aisne valley. Prepara- ns were completed by the evening of May 26 1918.

n the night of May 26–7 at 2 A.M. the German artillery bom- dment began, completely surprising the French and English. whole valley of the Ailette, the steep slopes of the Chemin- -Dames, the Chemin-des-Dames itself, and the country lying behind down to the Aisne, were in a short time thoroughly sed. After an hour and a half's bombardment, the opposing ntry and artillery were sufficiently subdued to enable the rman infantry to venture the assault.

The Infantry Attack.—At 4:40 A.M., while it was still dark, the German infantry advanced to the attack. Without difficulty or delay they crossed the Ailette valley, which was covered with bushes in some places and marshy in others; during the ascent to the Chemin-des-Dames serious infantry fights only developed at Chavignon, Pargny and Fillain; on the other sections of the front the German infantry pushed forward almost without resistance on to the heights of the Chemin-des-Dames. Here the remarkable effect of the artillery preparations was already apparent; the steep slopes had been surmounted and the first lines were taken almost without firing a shot. By 7 A.M. the I. Army had already reached the canal, and part had crossed it. Since they were to await the left wing of the VII. Army before further advance, a halt had to be made there, and the opposing army gained time to reform their units and to rally, while those in front of the VII. Army were overrun by the advance of the attacking divisions so long as they felt the effect of overwhelming German artillery fire. This was an essential difference between the attack of the I. and VII. armies, and was to be of decisive importance. By 9 A.M. the German infantry had reached the line Vauxaillon-Jouy-Pontavert-Berry-au-Bac.

Soon after 11 A.M. the first German companies crossed over to the southern bank of the Aisne on bridges mostly intact. A vast and unexpected success had been gained. A wide and apparently impassable stretch of country, which had been for years the scene of the heaviest fighting, had been captured within a few hours after a short artillery preparation. Of the divisions of the defenders two English and three French had almost ceased to exist. The survivors streamed into the prisoners' collecting stations, while countless guns stood abandoned in their positions, some of them undamaged. In the afternoon and evening the attack on the principal fighting front of the VII. Army went forward without a pause farther in the direction of the Vesle valley. Engineering and road-making troops worked with the utmost effort to level a path for the columns following through the enemy positions and over the steep way up to and down from the Chemin-des-Dames. On the two wings the advance was considerably slower. The Vesle was reached by the XXV. and IV. Res. Corps, and sections of the XXV. Res. Corps passed southwards of Courcelles and Paars, while sections of the IV. Res. Corps occupied the steep slopes at Fismes and Magneux. On this very first day of fighting the Germans had penetrated the enemy positions over a front of about 60 km. to a depth of about 20 kilometers. Over 15,000 prisoners and vast army supplies had been taken. The German losses were proportionately small.

Allied Resistance Increases.—The second day of the battle, May 28, saw the first violent counter-attack of the opposing army against the right flank of the German attacking troops. Nevertheless the speed of the German advance was not lessened on this day. On the right wing the LIV. Corps, after repulsing French counter-attacks, captured the heights north and northeast of Soissons. On the left the German divisions pressed forward until midday, over the whole sector of the Vesle, as far as the northwestern fort of the fortress of Reims. The objective was thus reached after a day and a half's fighting. But in the ardour of the pursuit the troops stormed on without orders, though in agreement with the intentions of the Higher Command, in order to improve their success by determined pursuit. The order given by the Supreme Army Command at noon of the 28th to continue the attack as far as the line of heights southwest of Soissons-Fère-en-Tardenois—the heights south of Coulonges—reached the troops when they were already storming forwards. On the right wing of the VII. Army, the VII. Corps had already joined the attack on May 28 without waiting for the completion of the preparations begun at this point. Here, however, the resistance was so obstinate that it was only in the course of May 29 that the dominating heights at Creçy-au-Mont were captured.

On the following days the VII. Army pushed on with its centre in a southern direction as far as the Marne. The right wing of the I. Army, which had extended the attack towards Reims on the left, pressed forward between the Marne and the Vesle against the wooded hills of Reims, but soon met here with unconquerable resistance. The right wing of the VII. Army took Soissons, and between the Aisne and the Marne gained ground towards the heights southwest of Soissons, and up to the eastern edge of the Forest of Villers-Cotterêts. On the 29th the occupation of the important road and rail centre of Soissons as well as of Fère-en-Tardenois was of tactical importance. In both places immense masses of material fell into the hands of the Germans. On the left wing all the roads and railways leading from Reims to the Marne lay under German fire.

French Counter-attacks.—On May 30 violent counter-thrusts by the French had held up the advance of the German right wing, while the German centre in a rapid advance had by midday reached the heights of the northern bank of the Marne between Château-Thierry and Dormans. On both days the pursuing German troops had passed beyond the objectives fixed by the Supreme Army Command, so that they reached the Marne earlier than had been thought possible. A further advance of the centre, pushed out southward like a wedge, beyond the Marne, seemed to involve great risk so long as the German wings on the east and west had not won further ground and thus been able to broaden the base of attack.

On May 31 instructions went out from the Supreme Army Command not to penetrate farther south over the Marne, but to extend the successes against the wooded heights of Reims and up the Marne towards the west in the direction of Villers-Cotterêts. On May 30–1, and particularly in the first days of June, strong counter-attacks were made by the French and later by the Americans. In the first days of June the fighting became steadily more severe, as the Allied resistance grew more obstinate and the counter-attacks progressively more violent and extended. The Germans therefore succeeded in gaining only little ground. The powerful impetus of the German attack had come to an end. On June 17 the German armies stood with their right wing and centre roughly on the line Noyon-Fontenoy, the eastern edge of the Forest of Villers-Cotterêts, Château-Thierry, and up the Marne to Verneuil; the left wing had penetrated to the outlying woods west of the wooded heights of Reims, and close to the west, north and east front of Reims, which was closely encircled.

Results of the Battle.—The tactical result of the battle of Soissons-Reims for the Germans was great beyond all expectation. Over 65,000 prisoners fell into their hands. The booty included about 700 guns and 2,500 machine-guns; in addition, the French and English losses in *matériel* were enormous. But there was a reverse side to the shield. The battle had brought home to the Germans that not only were there American troops now on the Western Front but that they possessed a fighting capacity and quality not hitherto suspected by them. The first notable appearance of American troops was at Cantigny on May 28. Here the American 1st Div., in taking and holding the village against the best efforts the Germans could make, had proved itself absolutely dependable. And within a few days the 2nd Div. had shown itself, in front of Château-Thierry, at Belleau wood and Vaux, to be a first class fighting unit. The conduct of these two divisions did much to hearten the Allies, whose morale had been somewhat depressed by the series of German successes since March.

The extent to which the fighting of the Americans impressed the Allied generals can be gauged from the change of opinion as to how best these reinforcements might be employed. For a time it had been thought that it would be too much to expect that America could produce, without a long probationary period, commanders and staffs capable of handling large bodies of troops in action under modern war conditions. By the end of June it was clear that American commanders and staffs were eminently competent to direct divisions in any battle. Early in July the American I. Corps took over a sector from the French VI. Army, a step amply justified by the resistance offered by the Americans at Château-Thierry in the middle of that month.

(F. E. W.*)

GERMANY (*see* 11.804), a Republic of Central Europe (Das Deutsche Reich). The German Empire, formed in 1871, included 26 states: the states of the North German Confederation, the South German states and Alsace-Lorraine. Until 1918 Germany retained this form unchanged, having an area of about 208,830 sq. m. and a population (1910) of 64,925,993 (estimated population, July 1914, 67,800,000).

I. AREA AND POPULATION

In Nov. 1918 Germany became a republic, and her states free states and, later, under the Constitution of Aug. 11 1919, territories of the German Reich. There are now 18 of these territories in the Reich, viz.: Prussia, Bavaria, Saxony, Württemberg, Baden, Thuringia, Hesse, Hamburg, Mecklenburg-Schwerin, Oldenburg, Brunswick, Anhalt, Bremen, Lippe, Lübeck, Mecklenburg-Strelitz, Waldeck and Schaumburg-Lippe. Under the Treaty of Versailles (Jan. 10 1920), Alsace-Lorraine was returned to France with validity from Nov. 11 1918; large areas in West and East Prussia, Pomerania, Posen and Silesia fell to Poland; portions of Schleswig-Holstein to Denmark; a small province of Upper Silesia to Czechoslovakia; Eupen and Malmédy to Belgium; the town and area of Danzig became a free state, and the Memel region was allotted to Lithuania. Germany's outline was thus changed, particularly in the east. Part of Germany, consisting mainly of East Prussia, was severed from the remainder by the "Polish Corridor" to the Baltic. The Rhine became to some extent the Franco-German frontier. Direct communication with Russia was cut off by Poland and the border states. Germany's present area is 186,517 sq. m.; it is bounded, W. by Holland, Belgium, Luxembourg and France; S. by Switzerland, Austria and Czechoslovakia; and E. by Poland and Lithuania.

This area had a population of 59,800,000 in 1919. On June 16 1925 the population was 63,250,000 (including the Saar valley, where however the census was not taken). There has been a steady increase in the density of population in Germany from 123·1 to the sq. km. in 1910 to 133·2 in 1925. Apart from the three city states of Hamburg, Bremen and Lübeck, Saxony is the most densely populated area (332 persons to the sq. km.); then Hesse and Baden. The least densely populated are the agricultural territories of Mecklenburg, Waldeck, Oldenburg and Bavaria (97 persons to the square kilometre). Prussia, with 120, is not far below the average for the Reich.

Increase of Urban Population.—In 1871 17·4% of the population lived in towns of more than 10,000 inhabitants; in 1925, 46·1%. The 45 towns with over 100,000 inhabitants absorb 16,500,000 or one quarter of the total population of Germany. The trend towards the towns is identical with the trend towards the workshops. This was specially noticeable during the years 1914–8, when internal migration assumed enormous proportions, being directed away from those places where the conditions of war had restricted production towards the centres of increased production arising out of war requirements. After the signature of the Armistice, there were extensive movements of population, still governed by prospects of production and therefore of wage-earning. At the same time rural districts experienced a not inconsiderable increase in population, as did also the coal-mining districts, the region of the Ruhr, Upper Silesia and the lignite districts, on account of the coal famine and consequent increase in production. In 1926 Germany was in the midst of a new shifting of the population, caused by the excess of coal and the attempt to put industry on a sound footing; this movement would be more pronounced but for the housing shortage.

The proportion of foreigners speaking their own language is now very small. There are many Germans outside the boundaries of the Reich. The contiguous wholly or partly German-speaking areas of Europe cover 15 states and include over 80 million Germans. The present area of the German Reich contained 38·1 million Evangelicals and 19·3 million Catholics in 1910. For figures of emigration and immigration *see* MIGRATION.

The birth-rate from 1870 to 1900 was consistently high (36·8 to 42·6 per 1,000). About 1·8 million children were born alive each year. The average annual surplus of births over deaths was approximately 600,000. The death-rate was also high, fluctuating during 1870–1900 between 21·7 and 31·0 per thousand. From 1900 onwards the birth-rate steadily decreased, and in 1914 it was only 26·8 per 1,000 of the average population. The death-rate declined from 23·2 per 1,000 in 1900 to 15·8 in 1913, and infant mortality from 207 per 1,000 infants born alive fell to 151. From the middle of 1915 the birth-rate dropped rapidly, and reached its lowest point in 1917, namely 14·4 per 1,000 of the population. In this year only 912,109 children were born alive. The rate of mortality rose during the same period owing to the War and the blockade. The highest death-rate was in 1918, when it rose to 25·2, assisted by the influenza epidemic. After the Armistice, the birth-rate began to recover. In 1920 it stood at 26·7, but then fell steadily until in 1924 it reached 21·1. The rate of mortality improved, once the blockade had been removed and the population were again able to obtain adequate nourishment. In 1921 the death-rate stood at 15·6 and sank again to 12·9 in 1924. The year 1925 brought further improvement.

The rate of births and deaths was as follows:—

ear	Total Births (inclusiv bi	Deaths e of still-rths)	Still-births	Per 1,000 of the population	
				Births (inclusiv bir	Deaths e of still-ths)
900	2,060,657	1,300,900	64,518	36·8	23·2
910	1,982,836	1,103,723	58,058	30·7	17·1
924	1,311,044	802,166	42,502	21·1	12·9

nfant mortality, which in 1913 was 151 per 1,000 born alive, was in 1920 and 108 in 1924. See *Statistisches Jahrbuch des Deutschen* *chs* (Berlin, annual). (W. Gr.)

II. CONSTITUTION

rom the Old Reich to the New.[1]—In the German Empire eich) the supreme authority was vested in the King of Prussia German Emperor, the Imperial Chancellor (appointed by the iser) as president of the Government, the Federal Council *undesrat*) representing the individual states, and the National presentative Assembly (*Reichstag*) representing the nation. e states—kingdoms, duchies, principalities and free states— l retained their sovereign rights, which they exercised in a ofold manner: first, in internal politics, by maintaining their n diets or councils, and secondly through the Bundesrat, ich, both in accordance with the rules of the Constitution l in practice, had a greater influence on the policy of the Reich n the Reichstag. Prussian hegemony in the Reich was not l down as a principle of the constitution but was a natural isequence of the disparity in size of the states.

Vhen the new Germany was constituted in 1919, the union of rman-Austria and Germany was made impossible by the aties of peace. This being so, Prussia's natural hegemony in rmany could be avoided only by the formation of a unified Reich by the division of Prussia into a number of provinces equal in to the other territories. But when the Constituent National sembly was elected on Jan. 19 1919 the question of a unified a federal constitution was overshadowed by other problems. e Communist party and a section of the Left Socialists re- ded this election and the demand for a constitution by the er political parties as bourgeois opposition to a dictatorship the Councils, and the Communists refrained from voting. e 185 Socialist deputies, who, like the Communists, stood for ntralism, were the strongest party, but could only form a jority with the help of the 75 Democrats, and, even so, they uld have opposed to them the German Nationals (44 deputies), German People's Party (19), the Catholic Centre (91) and seven deputies of the small Agrarian parties. The Socialists l Democrats were obliged to join hands with the third great publican party, the Catholic Centre, and thus there arose the called "Weimar coalition," supported by 329 deputies and er 23,000,000 votes, leaving out of account the Left Socialists, o still cherished hopes of a dictatorship.

The scheme for the new constitution was drafted by Dr. Hugo euss, former Secretary of State and at that time Minister of Interior. It was then reconstituted, by a commission ap- nted by the territorial Governments (*Staatenausschuss*), in such nanner as to strengthen the position of the individual terri- ies in relation to Preuss's unified Reich. In a special com- tee of the National Assembly, Erzberger, the actual leader of Centre, went over to the side of those who advocated a strong tral power for the Reich, and a resolution was passed which e to the Reich the financial authority which had hitherto ed principally with the territories (art. 8). On Aug. 11 1919 sident Ebert proclaimed the Weimar Constitution.

he Democratic Republic.—The preamble to the constitution s stress on the fact that the German people has given itself s constitution as by sovereign right:—

> The German nation, united in its peoples (*Stämme*) and inspired by the determination to renew and to establish its Reich in freedom and justice, to promote peace at home and abroad, and to further social progress, has given itself this constitution.

Between a monarchy and a republic there was no longer any choice. The choice lay rather between "direct" and "indirect" democracy.

"Direct" democracy is seen in the election of the president of the Reich by the most extended form of franchise in which "the whole German nation" takes part,[2] and in the Referendum which, however, is only admissible in the case of an adverse vote by the whole nation on a draft or a bill passed by the Reichstag [Initiative or Demand of the People (*Volksbegehren*), and Decision of the People (*Volksentscheid*), art. 73–6].[3]

"Indirect" democracy, on the other hand, is seen in the Reichstag, which has only one chamber, elected by the people entirely on the basis of proportional representation and with *scrutin de liste*,[4] that is, according to the party lists. No by-election takes place during the legislative period. The men at the head of the party list are replaced, when they go, by the men below them (art. 53, 54). The Ministry, which is nominated by the President of the Reich, must possess the confidence of the Reichstag; and, as the Reichstag is elected for a term of four years, and as a presidential election a national vote of censure or dissolution of the Reichstag only rarely occurs, German democracy is far more directly parliamentary than the Swiss or North American, both of which are frequently named as its models.

The President of the Reich may, after obtaining the countersignature of the Chancellor or other competent minister, dissolve the Reichstag, though such an expedient would of course only be resorted to in exceptional cases. Not only can the Reichstag force the Ministry to retire by a vote of no-confidence but, with a two-thirds majority, can submit to the nation a proposal for the deposition of the President (art. 43). A hundred members of the Reichstag can impeach president, chancellor or minister for having culpably violated the constitution or a law of the Reich. Judgment is then given after regular proceedings at law by a special Supreme Court (*Staatsgerichtshof*) (art. 59), not to be confused with the Supreme Court which sits at Leipzig.

The Reich and the Territories.—Of the 26 states which constituted the old Reich, 18 now (1926) remain and are called territories (Länder). The constitution prescribes a republican form of Government, but in other aspects the territories determine their own constitution, some of them having their own presidents. In their Parliaments the majority lies frequently with those parties who belong to the Opposition in the Reichstag. This is particularly the case in Bavaria where, since 1919, the Bavarian National party, belonging to the Right, has had a majority and forms the Government—and temporarily in Saxony and Thuringia, where in 1926 the Left Socialists and Communists held the majority.

The territories are represented in the central Government by the Council of the Reich (Reichsrat), to which their Governments (not their Parliaments as the Preuss scheme prescribed) send representatives. Each territory has at least one vote, but no one territory can have more than two-fifths of the total votes. In any case the number of votes is regulated according to the population (art. 61). Out of the 26 Prussian votes half are assigned to the Prussian provinces (of which Berlin is one) which are thus placed on the same footing as the other territories. On account of the peculiar majority regulations[5] in the provincial diets, these provinces sometimes vote against the policy of the Prussian territorial Government.

Unlike the old Federal Council (*Bundesrat*), the Reichsrat has no direct part in legislation.[6] The Government of the Reich lays its

---

The words *Das Deutsche Reich* were, before the revolution of Nov. 8, invariably translated "German Empire." But the word *ch* has, for historical reasons, been retained by the German Re- lican Commonwealth as its official territorial and political desig- ion. *Reich* is an old Germanic word found in Early and Middle glish, and surviving in composition in the word bishopric. (Ed. *E.B.*)

[2] Hence the expression "plebiscitary president."

[3] President and people may also work hand-in-hand, as when the president lays a bill that has been passed by the Reichstag before the people's referendum (*Volksentscheid*).

[4] The list is chosen, not the single deputy. In each electoral district as many seats are allotted to the list as the number of times by which the number of votes cast for that list is divisible by 60,000. Remainders are worked out in two ways: either by associating the lists within the electoral districts or by crediting the remainder to the Reich list of the party; here again 60,000 votes are necessary to elect a deputy.

[5] A candidate, in order to be elected, must have received one more than half of the number of votes cast.

[6] Still less does the Economic Council of the Reich (*Reichswirtschaftsrat*) possess legislative powers. It consists of representatives of the employers' and workers' organisations and of economists. The Government is obliged to consult the Council before placing social and economic bills of fundamental importance before the Reichstag. The Council can itself prepare such measures and bring them before that body (art. 165).

bills before it in the first instance, but if the Council reject them they can still be taken to the Reichstag. The Council also has the right to veto bills passed by the Reichstag, but this, again, can be overridden by a two-thirds majority in the Reichstag.

In respect of legislation, the competence of the Reich *ipso facto* excludes the competence of the territories in such important spheres as foreign affairs, migration, the army, commerce and communications (art. 7). Taxation is almost entirely administered by the Reich: citizenship, penal laws and legal rights were administered by the old Reich for all Germany, likewise the social laws. Of these, education alone was left to the territories, but now the Reich is concerning itself with that also.

In administration the territories take a larger part. Their Governments are still allowed to nominate the greater number of the officials of the so-called interior administration. The appointment of the revenue officials has, however, been taken from them since Erzberger's reform of the finance department of the Reich, and the Reich has also taken over railway administration, while the post office officials were, with the exception of Bavaria, already under the Reich.

The Reich has power to coerce the territories (art. 48). If they fail in their duties to the Reich or endanger its safety by disturbances in their areas, the President has power to take up arms against them and temporarily to suspend their territorial constitutional rights ("Federal execution"). The Reichstag may insist on the repeal of such measures if it disapproves of them.

The Constitution and Foreign Affairs.—Accepted principles of international law have in Germany the force of laws of the Reich (art. 4). Decisions on war and peace can only be taken subject to a law of the Reich. Alliances and treaties with foreign states require the consent of the Reichstag (art. 45, sections 2, 3). The president of the Reich appoints the officials of the Foreign Office, in the same manner as other officials, with the countersignature of the Chancellor or the Foreign Minister. In the case of ambassadors and attachés the President may claim a personal right of choice. Thus President Ebert associated himself in the selection of new candidates for nearly all the importa diplomatic posts after the World War. The Reichstag Co mittee for Foreign Affairs is permanent (art. 35).

The First Five Years of the Constitution.—The constitut stood the test of its difficult early years well. It gained in general esteem by the effective use that was made of armed fo (placed in the hands of the Government by the constitution) various emergencies. Its reputation was further enhanced by stabilisation of the currency, and by the fact that the pr mover in this—Dr. Schacht, president of the Reichsbank—was avowed partisan of the Republic. It was realised that such a constitution the economic life of the nation could be vived, in spite of the alarming art. 156, giving "authority the socialisation of the Reich." The article which is most verely criticised, in North Germany especially, is art. 3, wh orders that the colours of the Reich shall be black-red-gold is significant, however, that the majority of those who cling the old Reich colours would be willing to accept black-white as the colours of the Republic.

The territories demand greater independence in relation the Reich, particularly as regards the right to levy their taxes. This demand was definitely formulated in the memor dum of the Bavarian Govt. on the revision of the constitu (Jan. 5 1924).[1] But even Bavaria, the ancient stronghold federalism, only asks for the revision and not for the suppres of the constitution.

---

[1] A change in the constitution can only be made by a two-th majority in the Reichstag with two-thirds of the deputies presen the Reichsrat a two-thirds majority is required, and in a referen or people's decision a majority of the whole electorate, not only of actual voters.

Two attempts made in the Prussian provinces to create indendent territories by means of a plebiscite were defeated by e people themselves (Upper Silesia Nov. 3 1922; Hanover ay 5 1924). On the other hand, Saxe-Weimar, Saxe-Meiningen, xe-Gotha, Saxe-Altenburg and four small mid-German states ve united to form the free State of Thuringia; Coburg has ned Bavaria and Waldeck Prussia.[1]

The franchise and the one-chamber system have been widely ticised. The first presidential election showed that a candite who had not figured in the first ballot at all might be elected a relative majority in the second. But this President, ough elected by a minority, had after a year in office gained e confidence of an overwhelming majority of the people, ough losing, on the other hand, that of a portion of his electors. nilarly, President Ebert, who was elected by the Reichstag d not by the people, owed the strength of his position, even th the parliamentary parties, to the confidence with which his rsonality inspired large masses of the people. The franchise t only excludes strong action on the part of the people—a andslide "—but returns the same parties again and again with ly a slight alteration in the mandate, with the result that elecs become weary and indifferent. By-elections would serve the rpose of indicating to some extent the political feeling that tains among the people; and, further, as there is no upper use or senate, independent statesmen have no opportunity of icing the public opinion of the country. Neither is this want oplied by the big newspapers, which are almost all in the emoy of definite parties or definite economic groups.

III. POLITICAL HISTORY

The Domestic Situation 1910–2.—When Th. von Bethmann llweg, the fifth Imperial German Chancellor, presented himf to Parliament as Prime Minister of Prussia[2] in Jan. 1910, he oyed the confidence of the Conservatives, while the Socialists, erals and Catholic centre all opposed him. His bill for the eration of the Prussian franchise of Feb. 4 1910, which upheld " three class voting system " and open ballot, was rejected en by the National Liberals, while the Left Wing Liberals unded it as an insult to the very principle of franchise, and it s rejected in May, a coalition of all the non-Conservative rties in the Chamber of Deputies having decided to vote for secret ballot, while the Upper House rejected it.

In the Reichstag the opposition to the Chancellor was simily composed of the Centre, Liberals and Socialists. The Cath- Centre was the great patron in Germany of the Polish tholic minorities in the eastern provinces of Prussia. It there- joined with the Left in embittered protests when disciplinary ion was taken against certain non-political government offils (of the the postal and railway services) who had supported Greater Poland party in the municipal elections in Kattoz. The antagonism was the more violent since the Chanor himself belonged to the Prussian Protestant official class ich had used its social status to establish an unwritten monop- over the higher administrative posts.

f Bethmann Hollweg, later in 1917, was the champion of the reat coalition," extending from the National Liberals to the ial Democrats, and the particular *bête noire* of the Conservas, it was not he but the situation and the parties that had changed since 1910. He remained throughout a perfectly loyal and devoted public official, but stubborn and dogmatic, and contemptuous of the counsels of the outer world.

Bethmann's position, both at home and abroad, was difficult. The differences over the internal shipping dues had been laboriously composed, but the struggle still troubled the harmony of the confederated Governments. Saxony and Baden, in particular, as the two states lying on the upper courses of the Rhine and the Elbe, felt themselves overreached by Prussia, which, situated at the mouth, sought to abolish the traffic-dues on the great rivers in the interests of her schemes for canal construction. In Bavaria under the new Regent, subsequently King Ludwig III., the Government guarded the particularist rights and the parity of the state with Prussia far more jealously than it had done under King Ludwig II. or the Regent, Prince Luitpold. In the Reichstag, on the other hand, there was already a considerable majority which demanded stronger powers for the Imperial Govt. in its dealings with individual states. It called for the removal of the remaining restrictions imposed upon the Catholic Church in predominantly Lutheran states, and urged the Imperial Chancellor to take action in virtue of his imperial powers to abolish the old constitution of estates still in force in Mecklenburg, which entailed the domination of the great landed proprietors, and to establish a Diet with universal suffrage.

The question of framing a constitution for Alsace-Lorraine was particularly difficult. Those sections in the " Reichsland " most anxious for a permanent association with Germany—the German-speaking Old Alsatians and German Lorrainers, the industrialists and traders, the Centre party, official and university circles—demanded a " Home Rule " under which the Reichsland should become a federal state with full parity of rights, with powers to frame a state constitution by means of a Constituent Assembly, and representation in the Bundesrat proportionate to the population, the people electing deputies to the Reichstag and to the local Diet. This involved the question of the future position of the German Emperor, who had hitherto ruled as *de facto* sovereign, without a Diet, indeed often against the wishes of the Alsace-Lorraine deputies as expressed in the Reichstag. In any case, his powers as Supreme War Lord in a frontier and fortified region remained very effective even against the civil administration, and would outshadow those of another territorial ruler. Moreover, the mutual jealousies of the reigning houses made it hard to appoint a member of one of them to rule in Alsace-Lorraine. Yet if the Emperor, who was also King of Prussia, retained his position, with the right to appoint the Statthalter, the new state constitution would of itself entitle him to instruct the delegates of Alsace-Lorraine to the Bundesrat, so that their votes would simply strengthen the Prussian vote in that council. Finally, on May 26 1911, the Act embodying the constitution of Alsace-Lorraine was adopted as a compromise.

The territory was now to rank as a federal state; its constitution, however, was fixed by a decision of the legislative body of the Empire. Of the two Houses of Parliament, one was chosen by universal suffrage, while the other was in part nominated by the Government, in part composed of high officials. The Emperor remained reigning Prince, the votes in the Bundesrat thus deriving from his Government; but where a Prussian majority in the Bundesrat depended on the votes of Alsace-Lorraine the latter were not to be counted. Such an intricate constitutional instrument would probably never have been popular. It increased the confidence of the moderate middle-class parties in the Chancellor's domestic policy; but the Right and Left were equally dissatisfied. The Conservatives regarded any step towards constitutional Government in the Reichsland as unsound, and many of them would have preferred the continuance of rigid military rule in the " conquered " territory. Indeed, the hostility of the extreme Conservatives and of the Pan-Germans towards Bethmann Hollweg dates from this period. The Radical Left wing were alienated because they had hoped that the Constitution would do away with the dominance of the Prussian bureaucracy in Alsace-Lorraine and lead to parliamentary Government similar to that of the three South German States.

[1] Other small states will probably later join their greater neighbour es.

[2] He assumed that position in July 1909.

In other directions, also, in domestic politics the parties of the two wings began to move towards extremes. This process, at first interrupted by the War, was renewed with great violence afterwards, and still hampers the formation of anything like a two-party system, or, indeed, of parliamentary government at all. For the Right wing of the group of moderate parties which lies between these extremes cannot sit in the same cabinet with the extreme Left, whilst their Left wing cannot co-operate with the extreme Right. The Conservative party associated themselves with the agrarians, whose organisation, the Farmers Union (*Bund der Landwirte*), from the outset adopted demagogic tactics and appealed frankly to the power of the producers of indispensable foodstuffs. Heavy industry moved away from Liberalism and joined the agrarians; and the Pan-Germans, formerly recruited from the National Liberals, and the Anti semites drew closer to the parties of the Right, voting with them in questions of foreign policy and defence and collaborating with them at elections. In 1914 two of these Right parties, the German Party of Reform and the German Social Party, combined under an Anti semite to form the new Deutschvölkische Partei.

On Dec. 7 1911 the Reichstag was dissolved, the elections being fixed for Jan. 12 1912. The Government called for an alliance of the middle-class parties against the Socialists to "continue our present policy of commercial treaties and protection to German labour," and to "maintain our Army and Navy permanently in a state of the highest efficiency, and to fill up any gaps in our armament." The Association for combating Social Democracy issued the same message, which was indeed the same as had been used in the last elections by the Conservatives and National Liberals, but then against the Centre, to-day on behalf of the "blue and black bloc" of the Centre and Conservatives. The message was unconvincing, and in fact the elections brought the Social Democrats unexpected success. With 110 members they formed the strongest single party in the Reichstag, even as they had proved the largest single party in the electorate. They had gained 69 seats and lost 12. The three Conservative parties between them had gained 14 seats and lost 49, and even if with the Centre they still commanded about 170 votes, to 152 votes of the left, the decision upon tariff and fiscal policy now lay with the 45 National Liberal deputies.

The strength of the parties was tested in the elections of the President and Vice-Presidents of the Chamber. A Socialist—and that Scheidemann, particularly hated by the Conservatives on account of his speech in the Reichstag two years earlier, when he had said, "I am too well acquainted with Prussian history not to know that broken promises belong, so to speak, to the most exalted traditions of the ruling house of Prussia"—was for the first time elected first Vice-President. The President and second Vice-President resigned rather than work with him; in the end, after much juggling, the Progressives (who numbered only 41 deputies) secured the offices of President and first Vice-President, the second Vice-President being a National Liberal. Thus party intrigues perpetuated the curse of German political life, the exclusion of the Social Democrats from all positions of public responsibility; while the Centre, the second strongest party, was also excluded from presidential office. Another grave symptom was the fact that during these elections and in the work of the Reichstag organised commercial interests became an open political force. A vehement protest was made during the elections by an honest and uncompromising deputy, Count Posadowsky.

Foreign Policy before the War.—In foreign policy, too, Bethmann Hollweg had found a much more difficult situation than appeared on the surface. The secret documents of the Foreign Office, published as regards the years 1871–1912 in 30 volumes at the beginning of 1926, show where the key to the policy of the European Powers lay since the beginning of the 20th century, and why the Western Powers could consider themselves endangered by a threat of German hegemony at the same time that Germany could complain of isolation and "encirclement." The key lay in the unreality of the Triple Alliance, the southern partner of which could now only be considered an ally as a matter of form, not in reality. When Bismarck, after long hesitation an consideration, concluded the first treaty of the Triple Allianc in 1882 at Italy's request, relations between Italy and Franc in the Mediterranean were so strained that war between Franc and Italy was more probable than a French attack on German The Triple Alliance therefore gave security for immediate mutu help in case of a French attack on Germany or Italy; it afford Italy security and lent the necessary weight to its claims t the north coast of Africa and to equality of rights with Franc and Great Britain in all Mediterranean questions. When, however, Italy had come to an agreement with France on the delimitation of her spheres of influence in Tunis, Algiers and Morocc on the one hand and Tripoli on the other, and when the Egypt Morocco agreement between France and Great Britain (1904 had drawn Britain also into this Mediterranean entente, a danger for Italy of a French attack vanished, and thus any support from Germany became superfluous.

It was remembered also in Italy that it was precisely the fo eign ministers who had been true to the Triple Alliance who ha complained that Germany was holding Italy back from her natural expansion in North Africa out of fear of being drawn into Mediterranean conflict. This complaint over the passivity the Triple Alliance policy, which was especially clearly put b Baron Blanc in his great "Aide-Mémoire" of July 14 1895 t Lord Salisbury and to the other two Powers of the Triple Entent is the direct origin of Italy's *rapprochement* with France at th end of the 19th century. Since 1901 the German Foreign Offi and General Staff fully realised that even in case of unconceale French aggression, if it took place on the Rhine, Germany coul not reckon on the military assistance which Italy had promis to send her over the Brenner and through the Tirol and Sout Germany, and that no Italian Govt. would be able to let Ital fight with Germany against France, in the face of public opinio It is clear from a communication of Von Schlieffen, chief of th German general staff,[1] that public admission of this fact wa only prevented by fear that Austria-Hungary would lose all co fidence in the Triple Alliance, and even in the alliance with Ge many, if she learnt that in no circumstances could reliance b placed upon Italy's military assistance.

Even Prince Bülow, the most loyal friend of the Italian all ance deliberated whether it would not be better, in view of the re situation, to let the Triple Alliance lapse and openly admit Ge many's isolation. He believed, however, that the agitation whic such open dealing would at first provoke in Europe would brin such a great danger for peace that again and again he plaster over the rent. Consequently, whenever Germany was confront with a proposal for conference of the Great Powers, her Forei Office sought to avoid her participation. Such proposals alwa looked as though they would lead to an unbiased adjustment views between two equally strong groups of which neith could outvote the other; for in every issue between the Gre Powers, whether it arose over Morocco, the Near East, the Ba kans or the Far East, a State of the Triple Alliance and a State the Entente always at first appeared as adversaries. Their par ners played the rôle of mediating powers, two against two, an their parity seemed specially to fit them to bring about a compromise. Such was the apparent position. But the German Forei Office knew that Italy could not and would not stand by Austr in a German encounter with Great Britain or France, nor b Germany in a conflict between Austria and Russia, but that sh would always have closer diplomatic contact with France an Britain, and even with Russia, than with her Allies, who on the side did not usually consult her before negotiating on Balka questions with one another or with the Entente Powers.

When Germany did take part in the Algeciras Conferen (Jan. 10–April 17 1910), in fact insisted against the wishes France that this conference be held—the reason was that Ge many believed that she would be supported outside Europ

---

[1] It may be explained that Von Schlieffen retired towards the e of 1905. For the history of "the plan" up to the outbreak of Wa see the official record *Der Weltkrieg*, compiled from the archives the Reich, vol. 1, pp. 6–19 (Berlin, 1925). Ed. *E.B.*

Thanks to the ties which had been formed between the Emperor nd President Roosevelt by the German Ambassador Speck von Sternburg, Germany expected that the United States would dvocate the principle of the "open door" in the Moroccan question, and would join Germany in opposing the grant of a preferential mandate for France. Therefore Bülow did not then hink that Germany's isolation in Europe was an obstacle to the onference. All the greater was the disillusionment when Germany and Austria-Hungary stood alone at Algeciras as elsewhere. Bethmann Hollweg directly experienced not onlv this disappointment but the effects of Bülow's subsequent procedure in the Bosnian annexation crisis of 1908–9.

The Agadir Incident and the Settlement in Africa.—Since the rst Moroccan crisis the Emperor had acquiesced, though unwillingly, in the policy of the Chancellor and of the Foreign Office, articularly in Morocco and the Near East, and therefore the Foreign Office had always to strive to confront him with a *fait ccompli*. The Chancellor, who was naturally extremely pruent, took the responsibility for the sensational "Panther leap" to Agadir (July 1 1911). If a conference was to be avoided beause Germany was doomed to isolation (shared, at the very est, with Austria), an understanding made directly with France was essential. The Secretary of State, Von Kiderlen-Wächter, hought that this could be appropriately initiated by sending a warship to protect German commercial interests in Southern Morocco. He subsequently secured the Franco-German African Convention of Nov. 4 1911 after negotiations with the French mbassador Jules Cambon.

Kiderlen was neither a Junker nor a Prussian; he came from Württemberg, home of the South German spirit of independence nd democracy. He was, moreover, no militarist. He entertained keen, even personal hostility towards Admiral von Tirpitz nd the Emperor's military entourage, and was convinced that Germany could and must maintain her position by diplomatic means and without war. He claims for himself the credit of avertng the danger of hostilities between Austria-Hungary and Russia ver the annexation of Bosnia and Serbia's demand for compenation in Novi-Pazar. The Note of March 21 1909, in which ülow informed the Russian Govt. that Germany would "let hings take their course" if Russia did not accept her proposal or mediation, was drafted by Kiderlen; he had made its tone hat of an ultimatum in demanding from Isvolsky "a clear and ategoric answer, a precise answer—yes or no."[1] Kiderlen was t the time Ambassador at Bucharest, but in the interval he ssumed office as Foreign Secretary, in spite of the Emperor's ersonal dislike of him. He was the more inclined to a repetition f surprise tactics in diplomacy as they enabled him to exclude he Emperor himself from the direction of policy. Incidentally, Kiderlen treated Parliament even more brusquely, if possible, han he did his Sovereign and his military advisers.

The dispatch of the "Panther" to Agadir became known on uly 1 1911. On July 9 Kiderlen resumed his conversations with ules Cambon. At the end of the month the press of the Right nd Right Centre began to attack Bethmann Hollweg and the mperor himself for weakness towards France in Morocco. Kiderlen, in order to conciliate nationalist opposition to negoations with France, had created the belief that France would cede the French Congo entire to Germany; there was therefore eep disappointment when it became clear that Germany would nly receive a strip of territory securing her trade communicaons with the Congo river and the Belgian Congo. Bethmann Hollweg and Kiderlen, however, continued the negotiations. he Morocco-Congo Agreement was signed on Nov. 4 and pubshed on Nov. 7. Germany accorded a material recognition of he French protectorate over Morocco; France promised only eedom of trade and equality of treatment to the nationals of he European Powers, particularly as regards concessions for ublic works; but ceded to Germany 275,000 sq. km. in the north nd northwest of the French Congo, receiving in exchange 12,000 q. km. in the region of Lake Chad. Germany obtained access to the Congo river, while France acquired the right to construct military roads and a railway through the territory ceded to Germany, to connect the coast with the interior.

The Morocco agreement was, in general, welcomed by the Left but censured by the Right. The critics designated the newly acquired strip of southern Cameroon as worthless, and qualified the recognition of French predominance in Morocco as a feeble withdrawal before England's menaces, as expressed in particular in Lloyd George's Mansion House speech (July 21). The Chancellor defended the agreement in a great speech before the Reichstag on Nov. 9, in which he dealt in particular with the charge of irresolute policy:—

> From the very beginning our programme has been: to accord increased political rights to France only in return for increased security for our commercial interests in Morocco, and for the acquisition of colonial territory. We have not at any moment sought for territorial acquisition in Morocco itself. Negotiations between ourselves and France *alone*, not before an international congress, nor with the inclusion of a third party—this is the programme which we have laid down, and we have carried it out.

Diplomatic representations had been made in London respecting Lloyd George's speech. In the meantime, the British Govt. itself had held back, not desiring to intervene in the Franco-German negotiations. A "vigorous policy," such as the Right wing critics demanded, was only possible for Germany if she were strong on the Continent and avoided untenable positions outside Europe. Morocco had proved a festering sore not only in Franco-German but also in Anglo-German relations. The cause of peace was served by closing the wound. And finally:—

> Others, gentlemen, would favour a preventive war, against France, or against England, or against both together. But preventive war was a mistake, war must be avoided whenever possible. No one can tell whether hereafter Germany may be called upon to carry on war with her neighbours. The responsibility to-day is mine, and I say that it is my duty to conduct affairs in such a way that a war which might be avoided, a war which is not demanded by Germany's honour, is indeed avoided.

The Conservative opposition was directed by Heydebrand, known as the "uncrowned King of Prussia," and it was observed that the Crown Prince applauded him from the tribune in Parliament. The Crown Prince's criticism was really personal to the Emperor, and so William II. took it; he transferred his son from Danzig, where he was commanding a cavalry regiment, to work on the general staff.

This agreement had removed Morocco from among the direct political causes of a European war, even as the Franco-British Mediterranean agreement had removed Egypt. It was to be expected that new unrest would now break out elsewhere, and since the termination of the Russo-Japanese War the Balkans and the Near East seemed destined for this part.

German foreign policy was now concentrated upon the peaceful settlement of the Baghdad railway question, first by means of the agreement with Russia of Aug. 19 1911, and then on the negotiations which resulted in the agreement with Great Britain concluded in July 1914. The death of Von Kiderlen, on Dec. 30 1912, and of Marschall von Bieberstein, ambassador in London, (Sept. 24) were serious losses to the German diplomatic service. The death of Marschall dangerously reinforced Austrian influence in Berlin. As the most energetic promoter of friendship between Germany and Turkey, Marschall, from his post at Constantinople, had strongly opposed all Austrian encroachments in the Balkans, particularly before and during the Bosnian crisis of 1908–9. Unlike Count Aehrenthal, he never allowed himself to be influenced by prejudices of domestic policy in his idea of the necessary co-operation between the three Empires. As Ambassador in London, a post which he had hardly assumed when he died, Marschall would probably also have easily found the right attitude towards English Parliamentary policy.

The Turco-Italian War, for which Emperor and people alike strongly condemned the Italians, would probably have injured the Triple Alliance more if any illusions had been entertained in Berlin. It was only because nobody expected Italy to have any regard for her Allies that Germany was content to look on while Turkey, the only Power with which she was in close and friendly relations, was deprived of one of her provinces and suffered heavily from the war. During the war, on the occasion of the Emperor's visit to Venice in March 1912, the stability of the Triple Alliance was affirmed. In Dec. 1912 the Alliance was renewed without comment, its renewal on each previous occasion having been preceded by protracted negotiations. When the first Balkan War (1912) gave rise to a new and acute danger, and mobilisation seemed imminent on the Austro-Russian frontier, with all the results which it entailed in the summer of 1914, German policy, in close co-operation with that of Sir Edward Grey, brought pressure on Vienna, whilst the Emperor used his influence with the Archduke Francis Ferdinand, during the latter's visit to Springe (Nov. 22–3 1912), to dissuade Austria from threatening Serbia, and Russia from emphasising her rôle of Serbia's protector. The supporters of the policy of preventive wars were bitterly disappointed, and they spread broadcast an utterance attributed to the Emperor, in which he was said to have insisted that " the Austrians must not rattle the German sword."[1]

---

[1] *Grosse Politik*, No. 9,460.

Home Politics 1912–4.—In the two years preceding the outbreak of the War, however, the foreign political situation was much less acute than the domestic. In the former field may be mentioned the characteristic incident of the Emperor's visit to Switzerland, with the sincere good feelings which it aroused, and his energetic commendation of the Swiss citizen army (Sept. 3–5 1912). The year 1912 brought the first ominous symptoms: the plans for strengthening the army and navy (the latter unhappily coinciding with the visit of Lord Haldane to Berlin); the resignation of Wermuth, Secretary to the Imperial Treasury, in March 1912, which was interpreted as an abandonment of the death duties; the miners' strike of March 1912, and the much more serious and enduring phenomenon of the rise in meat prices in the autumn and winter of 1912–3—a powerful weapon of agitation in the hands of the Left, for the Agrarians of the Right and Centre opposed the import of cheap foreign meat; the even more threatening insecurity of the Parliamentary majority, for a violent contest had arisen between the two Protectionist parties of the " blue and black " bloc since the campaign opened by the Centre (originating in Bavaria) to secure the abrogation of the Jesuit law. On that question the National Liberals voted with the Conservatives; the Left wing Liberals and Socialists, as opposed in principle to all exceptional legislation, with the Centre.

But, above all, the Emperor and the Prussian Court and military authorities were finding great difficulty in accommodating themselves to the new conditions in Alsace. Almost all the conflicts of this period arose among the German-speaking and German-bred Alsatians and not in predominantly French Lorraine. When the administration of Alsace withheld Government orders from a factory in Grafenstaden on account of the alleged provocative and anti-German conduct of the manager, it had the Landtag against it (unanimous vote of censure by the second Chamber on May 7 1912). At a dinner given by the Governor in Strasbourg the Emperor had expressed the intention of destroying the Alsatian Constitution and converting Alsace-Lorraine into a Prussian province if matters went on like this. This was not taken very seriously by the Alsatians themselves. The Alsatian papers even admitted that it was comprehensible that the Emperor should feel the opposition of the Landtag as ingratitude. In the Reichstag, however, Scheidemann seized upon the Emperor's pronouncement to remark that in any case to become Prussian was the harshest punishment Germany could inflict. The Chancellor and the Ministers walked out, and the President afterwards called the speaker to order. But the Social Democrats had moved a stage further Left.

Social Legislation.—The principal sufferers from stringent conditions in the German Reich were the numerous Government administrative officials (members of the post-office, railways, revenue office, clerks), although their loyalty made them slow to voice their grievances. The manual workers vented upon the big stores, the chief of which were in the hands of Jews, their anger at the high prices of necessaries and became anti-Semites. The workers who were organised in trade unions were materially not badly off. State insurance for disabled persons and dependants of the deceased, for the victims of accidents and for the sick, was now established on a uniform basis for the Empire (Imperial Insurance Act of July 19 1911). Considerable power was assured to the operatives, particularly in the establishment of the local sickness funds, so much so that the doctors constantly complained that they were at the mercy of the local officials concerned with the funds, who were almost all Social Democrats. For a time the doctors even threatened to strike on this issue. A new chapter of jurisprudence of great importance was opened: the " Labour Laws." This summed up in a comprehensive code the regulation of conditions of labour under public and civil law. There was also talk of establishing " labour courts " in which civil cases between workers and employers were to be decided. The court was to consist, on the model of the industrial and mercantile courts, of a lawyer as president and two assessors (one an employer and one a worker), elected by the employers and workers of the district. In these elections the principle of proportional representation was tried for the first time in Germany on a considerable scale. The formation of chambers of labour was also planned. These were to have the same standing in economic life as the chambers of commerce and of agriculture. They were, however, to be formed on a footing of equality—that is to say, workers' representatives were also to be included.

On July 1 1912 persons in receipt of disablement pay numbered 953, 057; in receipt of sickness benefit 15,866. Old age pensioners numbered 91,331; and the total pensions paid since Jan. 1 1900, 510,838. Under the provision for pensions for the widows and orphans of insured persons in the Act of 1911, 4,562 pensions had been paid by June 30 1912 and 1,059 single grants.

The Centenary Commemorations, 1913.—The year 1913 opened with festivals commemorating 1813, and what to the German people was the great war of liberation of its history. It was a genuine celebration of freedom and a national festival. The German dynasties, the governments and the political parties showed themselves ready to allay old quarrels. The betrothal of the Emperor's daughter to Prince Ernest Augustus of Brunswick, the grandson and heir of the last Guelph King of Hanover, brought about a reconciliation with the Duke of Cumberland, whose son ascended the throne of the federal state of Brunswick. It was announced on the Emperor's 25th jubilee (June 16) that he had destroyed a secret testament of Frederick William IV. in which the latter had enjoined upon all his successors to abolish the Prussian Constitution before assuming rule. On the occasion of the Emperor's jubilee, for which almost all the federal Princes assembled in Berlin, the Prince Regent of Bavaria, Ludwig, who in Nov. 1913 was empowered by law to assume the royal office in view of the persistence of King Otto's incurable mental ailment, pledged the loyalty of the states to the Empire. In reply, the Emperor styled the sovereigns of the German states and the burgomasters of the free towns his " allies," and declared that in their independence, as guaranteed by the Constitution, lay the strength of the Empire itself. In the Reichstag the motion of the Centre on the Jesuits was adopted on Feb. 19 1913, after a peaceful discussion. During the debates on the colonial budget, Erzberger, formerly the keenest critic of the abuses existing in certain colonies, supported the colonial policy of the Government.

Passing of the Army Reform Bill.—Even the Army bill, officially announced on March 1, encountered no very bitter opposition. The bill increased the peace strength from 544,271 men to 661,176, entailing the creation of 84 new battalions and squadrons. The total cost was to amount to an initial outlay of 1,050 million marks, and subsequently of 180,000,000 to 190,000,000 marks annually. The initial costs were to be covered by a capital impost for one year only, and in the case of high incomes by a single levy on income (" contribution towards national defence ") both non-recurring. The current expenses were to be met by an increase of the quota contributed towards the Imperial finances by the federal states, which those states levied through their own taxation upon capital or income. The discussions in the Reichstag turned less upon the strengthening of the Army than upon the means of meeting the cost. The Left wing parties demanded, and in part secured, that property, particularly unearned increment, should bear the chief burden of the single levy, and further the introduction of a steep, progressive graduation of the rates of taxation. Apart from the fact that they were in general favourable to the Army bill, the parties of the Right found satisfaction in the abandonment, at any rate for the time, of the plan of permanent death duties. On the death on Aug. 13 of Bebel, the venerable leader of German Social Democracy, all parties united in a tribute of respect to his character, and integrity and none denied that he was a "good German."

---

[1] The official records of the conversations in politics between the Emperor and the Archduke at this meeting, and at the Emperor's subsequent visit to Konopischt in June 1914, will be published in volumes 32 and 35 of the collection of German archives: *Die Grosse Politik der Europäischen Kabinette.* Until their appearance it is wiser to suspend judgment.

The Zabern Incident.—Yet how delusive was this tranquility was manifested by the Zabern incident of Nov. 1913 (*see* ALSACE-LORRAINE); an incident so trivial in itself that its prodigious consequences can only be explained by the existence of a general state of political tension. The Government's position was weakened, for its attitude over the incident was censured by 293 votes against 54 in the Reichstag, unanimously in the lower Chamber of the Alsatian Landtag and by 33 votes against three in the upper Chamber. At the same time the Imperial Chancellor had incurred the definite hostility of the military party. In an important debate in the Prussian Upper House on Jan. 10 1914 Bethmann Hollweg developed his whole policy in a discussion with the spokesman of the Conservatives, Count Yorck zu Wartenburg. Zabern was not discussed, but it was present in the thoughts of every speaker. Bethmann defended the constitution of Alsace-Lorraine. He vindicated his right, disputed by Count Yorck, of calling a commission of inquiry with the co-operation of deputies of the Reichstag to report on the conditions and abuses in the army contracts' department. But he, on the other hand, admitted that precisely in the Empire with its universal and free suffrage and the social tendencies of its legislation a Prussia with a different "internal structure," that is without universal suffrage and without responsible parliamentary government and with a "firm military foundation," seemed essential.

The Government aimed at compromises between the Emperor and Parliament and between Prussia and the Empire. But the parties and the politically minded section of the nation all felt that alike in domestic and foreign politics the Government was lacking in decision. How little, however, the professional politicians knew of the reality may be seen from the fact that the appointment of Herr von Loebell, who during and after the War proved himself a leader of the reactionaries, as Prussian Minister of the Interior was characterised as a concession to Liberalism.

THE WAR PERIOD

The Sarajevo Murder.—When the news of the murder at Sarajevo on June 28 1914 became known in Germany, the horror generally felt was mingled in pacifist circles with a certain silent relief. Rumour had assigned the murdered man to the war party. From the new heir to the Austro-Hungarian throne a peaceful policy might be expected. It was anticipated that Austria-Hungary would take speedy action against Serbia, as far as possible in agreement with Russia. It was thought that the sympathies of the world were on Austria's side, even if she should undertake a short punitive expedition against Serbia.

The most recent and very meticulous examination of all the archives and the utterances of all witnesses have made it clear hat in the early days of July the Emperor and his entourage had no thoughts whatever of a European war, and that neither a Crown Council, still less a Council of War—as the American Ambassador Morgenthau claimed to have heard from the German Ambassador in Constantinople—was held in Potsdam or Berlin, But when Von Tschirschky, the German Ambassador in Vienna, eported on June 30 that Vienna desired to use the opportunity o settle accounts with the Serbs thoroughly, but that he himself eized every occasion to "issue calm but very emphatic and seri-us warnings against precipitate action," the Emperor commented: "Who has authorised him to do so? It is very stupid. It is no business of his. What Austria thinks of doing is solely her affair." Thenceforward the Ambassador let the Austrians go their own way, and as on July 5 the Emperor had received a letter from the Emperor Francis Joseph and a memorandum drawn up by Count Berchtold, and the Chancellor had declared that in harmony with his obligations as an ally the Emperor would stand loyally by the side of Austria-Hungary (July 5 and 6), Vienna felt that it could rely on German aid in its Balkan plans. But the Emperor and the Chancellor merely intended that Austria should demand satisfaction from Serbia as speedily and energetically as possible, before the murder of the heir became a European question. It, therefore, implied no change of view that the Emperor received the Serbian answer to the Austrian ultimatum of July 23 with the comment:—

> A brilliant achievement for a grace of 48 hours. It is more than could have been expected. A great moral triumph for Vienna. But every reason for war now disappears, and Giesl ought to have remained quietly at Belgrade. On the strength of this I would never have ordered mobilisation.

When Austria rejected the Serbian reply, and on July 28 declared war on Serbia without having previously consulted Berlin, the Chancellor and the Secretary of State, Von Jagow, realised the danger of the position—no doubt much too late. On July 29 Bethmann telegraphed to Vienna:—

> I view the attitude of the Government in Vienna and its inconsistent attitude towards the different Cabinets with increasing discomfort. In St. Petersburg it asserts its territorial disinterestedness, it leaves us entirely in the dark as to its programme, feeds Rome with meaningless phrases regarding the compensation question, whilst in London Count Mensdorff gives away portions of Serbia to Bulgaria and Albania and proceeds to contradict the solemn declarations in St. Petersburg. From these contradictions I must draw the conclusions that . . . the Viennese Government harbours plans which it deems it wise to conceal from us, to assure itself in any event of German support and not by an open avowal to run the risk of a possible refusal.

For a conference, however, as proposed in particular by Grey, Berlin was equally disinclined, as conferences had always been unwelcome to her since Algeciras. The last hope, therefore, lay in successful direct negotiations between Vienna and St. Petersburg. When these broke down on July 30, Germany supported in Vienna (July 30) the final British proposal for mediation to the effect that after the capture of Belgrade, Austria should announce her intention of advancing no further until the Powers should have mediated between herself and Russia. Count Berchtold's temporising defeated this proposal. With the general mobilisations of Russia and Austria on July 31 and that of Germany on Aug. 1 a state of war was actually in being, although the declarations of war followed later. For in the three states immediately involved the chiefs of the general staffs were now unanimous in asserting that any further delay would endanger the prospects of success in the field, and no civilian Chancellor could take the responsibility of opposing this view. Moreover, the executive power had now passed in accordance with the Constitution to the supreme military authority. (*See* also EUROPE.)

The Invasion of Belgium.—The German plan of campaign for a war on two fronts, as framed by the elder Von Moltke, had envisaged defensive action on the west, offensive on the east. Subsequently for a short time there were two alternative plans. The official account of the War by the German general staff proves that in 1892 under Count Schlieffen the plan of an eastern offensive was abandoned, the offensive on the western front with the march through Belgium being retained as the sole plan. The Foreign Office was not consulted.[1] The Emperor made a single allusion to the plan in a personal letter to Prince Bülow, who returned a dilatory answer. Bethmann Hollweg and his Secretary of State for Foreign Affairs, Von Jagow, were never asked whether they approved of the military plan which contemplated an offensive against France and the violation of Belgian neutrality. According to the Constitution, the Emperor, as Supreme War Lord, had to decide during war time in cases of differences of opinion between the civil and military authorities. But once set in motion, the machine of mobilisation revolved so rapidly that even the Emperor could no longer have interposed. Bethmann Hollweg declared in the Reichstag on Aug. 4 1914:—

---

[1] It is necessary, however, for the understanding of the Schlieffen plan, which originally contemplated the violation of Dutch as well as Belgian neutrality, to read *Graf von Schlieffen*, by Freytag-Loringhoven (Berlin, 1920), and also *Erinnerungen, Briefe, Dokumente 1877–1916*, by the second Von Moltke, especially pp. 429, 430 (Stuttgart, 1922). From before the end of the 19th century the manoeuvres were obviously based on the principle of a turning movement through Belgium and Luxembourg (Reichsarchiv, *Der Weltkrieg*, vol. 1, Berlin, 1925); the Kaiser's statesmen were aware that strategical railway facilities were continually developed in the same direction and provided for in the Budget. There is no doubt that the Schlieffen plan was officially regarded as a life-and-death necessity of German policy in case of war.—Ed. *E.B.*

> We are now acting in self-defence, and necessity knows no law. Our troops have occupied Luxembourg and have perhaps already entered Belgian territory. This is in contravention of the behests of international law. It is true that the French Government stated in Brussels its intention of respecting the neutrality of Belgium, as long as the enemy respects it. We knew, however, that France was ready to march in. France could wait, we could not. A French flank attack on the lower Rhine might have proved fatal. We were thus compelled to disregard the justified protests of the Governments of Luxembourg and Belgium. The wrong that we are thereby inflicting —I speak openly—we will strive to repair as soon as our military objective is attained.

Early Stages of the War.—The parties concluded a truce, and the Social Democrats voted credits for the War, which they regarded as a defensive war against Tsarist Russia. The people everywhere accepted the situation very gravely. The immediate summons to the colours of the whole Landsturm up to 45 brought home the danger to all. The general nervous feeling during the first weeks was betrayed in the hunts after spies and transports of Russian gold. When the first prisoners of war arrived, the military authorities feared that the people would fraternize with them, and strictly forbade any intercourse. The civil authority at home was transferred to the Generals commanding Army Corps Areas in Germany, whose staffs consisted usually of superannuated and not always very intelligent officers, who were entrusted with all emergency defence measures and with censorship of the press and all other printed matter. Thanks to the censorship, the defeat on the Marne could at first be kept almost entirely secret. The war for positions was declared to be the deliberate plan of the general staff. Although Von Moltke was dismissed, and although it was already determined that the High Seas Fleet should not risk itself in open battle, General Headquarters still hoped for victory. The fatal effects for Austria of the failure to give her speedy help against the Russian army were not realised, especially in view of Hindenburg's striking success in the East.

It thus seemed clear that the prolongation of the War and all the accompanying distress was solely due to the blockade. This blockade, initiated by Great Britain, was regarded, like the sequestration of enemy property, as a violation of international law. Since the Anglo-American conception, which treated individual nationals of enemy states as "alien enemies," was new to Germany the opinion arose that it was the specific English mode of warfare—as distinct from the French or the Russian—which was inhumane and contrary to international law, particularly as the indignation aroused in Europe, and especially in France by the application of the same methods in the Boer War was not forgotten, while of course the decisions in British and American courts on which the blockade rested were unknown.[1] In the first year of the War the conviction had already arisen that the German army was invincible, and that the sole source of danger lay in the "war of hunger" which threatened women and children. If the population at home could "hold out," in the end the War must be won.

As the War dragged on questions of internal politics and economics revived. The people considered that their sacrifices in human lives—volunteers, officers of the reserve, substitutes as well as those on active service—and the privations which they had borne in meeting the costs of the War and in the internal loans, which had been in the first instance subscribed by the holders of small savings-funds, entitled them to claim full political rights. The Reichstag voiced this opinion and the rights of the civil authority with increasing firmness. The civil administration, however, was powerless against the military authorities. Since General Ludendorff had become Quartermaster-General, and a number of his personal adherents had converted the War Press Bureau, and later the "patriotic instruction" given to the troops, into an instrument of political propaganda, the Zabern episode was re-enacted on a large scale. The military authorities thought the Chancellor and the Foreign Office too weak in their attitude towards foreign countries and towards the Reichstag, and that when the civilian authority broke down the military must take over their duties.

The real test of strength came on the question of submarine warfare, to which the Chancellor, the Foreign Office and, of the other ministers in particular, Helfferich, the influential Secretary to the Imperial Treasury, stood opposed, when General Headquarters demanded it again in 1917 after the conferences at Pless of Aug. 30 1916 and Jan. 9 1917.[2] The supreme military authorities, supported by the chief of the naval staff, pointed out that the exchange of Notes between the German and the Entente Govts. with the United States and the other neutral Governments between Dec. 12 1916 and Jan. 12 1917 had proved that peace offers could not be negotiated through diplomatic channels.

The German Peace Offer, Dec. 1916.—That might be true, but the intrinsic weakness of the German Notes (*see* EUROPE) had resided in the fact that public opinion, the Reichstag, and possibly the Government itself, falsely informed by General Headquarters on the military position, considered the offers contained in them to be quite acceptable and even generous. In particular, no plain admission of a duty of reparation towards Belgium was made, because General Headquarters insisted that if Germany was to renounce territorial aggrandisement she must receive guarantees in the West and East. Moreover, heavy industry, at that time closely allied with General Headquarters, desired to see the economic predominance of Germany in Belgium and northeastern France established by the conditions of peace. Bethmann himself and after him Helfferich at length gave way to the military authorities Jan. 9 1917, and the Emperor issued orders to begin unrestricted U-boat warfare on Feb. 1. When on Jan. 23 1917 President Wilson proposed mediation to Count Bernstorff through Colonel House, and inquired the German terms of peace, the Chancellor, who received the communication on the 28th, lacked the strength to stop unrestricted U-boat warfare, and thereby destroyed his own position. He remained in office long enough to issue the so-called Easter message of April 7 1917 from the Emperor as King of Prussia, in which the abolition of the Prussian three-class franchise was promised, in order to reconcile the Social Democrats. But the new "Fatherland party" ("Vaterlandspartei"), which enjoyed the support of General Headquarters, and in particular its co-founder Kapp, attacked the Chancellor without mercy. When he fell at last, this was partly due to Erzberger's attack in the Main Committee of the Reichstag on July 6 1917 (recording the complete failure of U-boat warfare); partly to the military leaders who had come to Berlin on July 7 and, above all, to Ludendorff's *alter ego*, Colonel Bauer; finally, Ludendorff and Hindenburg extorted the resignation of the Chancellor from the Emperor by threatening their own resignation (July 13).

His successor, Michaelis, was nominated at the instance of the Emperor's entourage, without negotiations with the Reichstag. His restrictive interpretation of the peace resolution of the Reichstag, adopted on July 19 1917, deprived it of all value abroad (*see* EUROPE). His ambiguous attitude, moreover, was partly responsible for the failure of the pacific activities of Pope Benedict XV. in Aug. 1917. The Vice-Chancellor Helfferich was the most influential member of the Government. He en-oyed the special confidence of the Supreme Command, whose views he regularly imposed on the civilian authorities.

---

[1] For the general case *see* BLOCKADE.

[2] The first occasion was Feb. 4 1915, when the Government—this time against the advice of Tirpitz—declared the British territorial waters to be a war-area as from Feb. 18. Mr. Wilson's mediatory proposal, that Germany should recognise the rules in force for cruiser warfare as applying to U-boat warfare, and that in return England should permit the passage of American provisions, failed. When the "Lusitania" was sunk, the protest of the United States of May 15 resulted in the suspension of the U-boat war (July 8 1915; finally on May 4 1916).

Economic Measures.—In the meantime, the economic structure of the German Empire had undergone a complete change. On Aug. 8 1914 Walter Rathenau founded the department dealing with raw materials for war industries in the Prussian War Office (“ Kriegsrohstoffabteilung des preussischen Kriegsministeriums ”), which for a considerable time met the demand for the chief imported raw materials of war industries, particularly metals, cotton, grease, india-rubber and glycerine, by economic handling of home supplies, organising imports from neutral countries (“ compensation trade ”) and by stimulating the discovery of substitutes (nitrogen from the atmosphere, raw material for textiles from nettles and wood, etc.). Foodstuffs were early rationed. The yield of the soil declined owing to the lack of manure and skilled labour. Ration cards were introduced, first for bread, then fats, sugar, milk, eggs, meat and potatoes. From the winter of 1916–7 onwards, the quantities allowed no longer sufficed to nourish children and young people. The home producers were also, in principle, limited to these rations; but watertight control was impossible, and smuggling and illicit sales became habitual. The sequestration of brass and copper articles in the smallest households excited much bitterness, since it was suspected that the treasures of the rich were being spared, those of the poor taken.

While the economic capacity of the individual, particularly of the lower middle-classes and officials, was thus physically and morally undermined and the mass of the population compulsorily socialised, on the basis of a bare subsistence rate, the economic capacity of individual industries expanded enormously, and the workers employed in them demanded a higher standard of living. The so-called “ Hindenburg Programme ” (Hindenburg's only in name) carried out by the War Department (*Kriegsamt*) founded on Nov. 1 1916 in accordance with the law of auxiliary services (*Hilfsdienstgesetz*), was a prime cause of the economic collapse. By an economically unjustifiable increase in munition workers' wages it disorganised other industries, in some cases brought about a stoppage and constructed at enormous expense blast furnaces which stood idle for lack of fuel. The “ conscription of labour ” provided welcome material for radical agitators, while the melting down of church bells offended the devout. War expenditure rose from two milliard marks a month in Aug. 1916 to more than three milliards in Dec. 1916, and to almost five milliards by Nov. 1918. Moreover, this programme laid the foundations of the political power of the great Rhineland-Westphalian industrials.

In the autumn of 1917 the civil authority reasserted itself. Helfferich was replaced by the Democrat Payer, from Württemberg. From Nov. 1917 the “ Interparty Commission ” of the Reichstag, in which Erzberger and Scheidemann were the chief figures, sat in permanence. On Jan. 24 1918 the Emperor stated to Hindenburg and Ludendorff that he himself and the Chancellor bore the sole responsibility for the direction of political issues. In reality, however, particularly since General Headquarters had forced on him a new Chief of Cabinet, the Emperor was entirely subservient to the military authorities. The Supreme Command took its revenge in 1918; the Peace of Brest Litovsk with Russia (March 3 1918) and of Bucharest with Rumania (May 7 1918) were purely military dictates, bringing no lasting goodwill; although it is true that only a dictated peace could bring Finland and the border states freedom and self-determination.

General Headquarters regarded the spring offensive of 1918 as the last chance of securing a peace “ which should strengthen the monarchy and extend Germany's power.” When it broke down, the War was lost from a military standpoint; even Ludendorff recognised this on the “ black day ” of the breakthrough at Villiers-Bretonneux (Aug. 8 1918). In Sept. and Oct. the Bulgarian, Turkish and Austrian fronts collapsed.

On Sept. 24 the Main Committee of the Reichstag brought Social Democrats into the Government as Secretaries of State, reformed the Prussian franchise and proposed full autonomy for Alsace-Lorraine. Prince Max of Baden became Chancellor; but General Headquarters retained their influence, especially as the Emperor always retired to their shelter at any decisive moments. The Supreme Army Command determined the specific character of the notes sent by the German Govt. to President Wilson in Oct. 1918, and demanded that the note asking for an armistice should be sent out on the night of Oct. 3–4 at the latest, in view of the threatened collapse of the German front; and were also responsible for the second note of Oct. 12, dictated by the necessities of the military situation. Only when Wilson's note of Oct. 14 had to be answered did the Cabinet withstand the views of Ludendorff, who now again asserted that the front line could be held, and themselves continue the exchange of notes with President Wilson.

On Oct. 26 the Cabinet obtained Ludendorff's resignation,[1] and Hindenburg thereby regained the simple and honourable position, free from the taint of politics, which had won him the people's confidence in the early years of the War, and now enabled him to lead the army home, in the face of the pursuing enemy, without the occurrence of mutiny or plunder. Ludendorff did not, indeed, leave his post as Quartermaster-General without first disseminating the contention later known as the “ legend of the stab in the back,” that it had been the slackening of resistance at home which had made it impossible to the army to continue fighting.

THE REVOLUTION AND THE REPUBLIC

The fall of Ludendorff was deeply significant. The essence of Prussian tradition had always been the subordination of the civilian to the military power. In the first successful years of the War this tradition had naturally been fortified, and the military had assumed even more complete control over the conduct of politics. The Emperor and his entourage were entirely dominated by the Supreme Command, as was much of what ought to have been sensible Conservative opinion. When military defeat approached, the Vaterlandspartei and similar circles, like the Emperor, attributed it, not to errors or weakness of the Supreme Command, but to the fact that civilian authority and opinion had not yet been entirely stifled.

---

[1] For a fuller explanation of the circumstances *see* LUDENDORFF.

In moderate liberal and democratic circles exactly the opposite process took place. Their leaders were driven by the intransigent and imperialist attitude of the extreme Right into strong sympathy with the Left. The great party of the Left was Social Democracy; but now when events seemed to be laying the future in its hands German Social Democracy found itself fatally disunited. Hampered by the undemocratic Prussian franchise and much frank repression, the German Socialist party had yet grown rapidly during the years of stress and rising prices which preceded the War. It had achieved a stake in the country, a complex organisation and considerable funds. Fear of losing these acquisitions, combined with natural patriotism and the dread of Russian autocracy, determined the attitude of the party leaders towards the War. On the crucial Aug. 4 1914 they abandoned the International; voted unanimously for the War credits in the Reichstag and concluded a "truce" with the other political parties. In return the Emperor, under pressure from the Government removed the restrictions on Socialist literature and admitted organised workmen into the state railway and other services. On Sept. 9 the Socialist leaders protested against the anti-German attitude of the International Socialist Bureau; and their spokesmen vigorously defended their national cause in the already vexed question of War guilt.

The moderate Socialists had really moved towards the left centre. A small fraction, however, dissented. In May 1915 one voice—that of Liebknecht—voted against a fresh War credit; and a group under Liebknecht and Rosa Luxemburg began to agitate for refusal of credits and a general strike to stop the War. In Nov. 1915, 18 Socialist deputies voted against the credits. The opposition now grew rapidly, but was itself divided. The larger group, under Haase, Kautsky, Ledebour and Bernstein, split definitely from the majority in March 1916 over the question of submarine warfare, and formed a separate group which at Easter 1917 took the title of the "Independent Social Democrat Party of Germany," with a programme of early peace without annexations. The extreme Left under Liebknecht (which in 1916 had begun to issue a secret paper named *Spartacus*) was already in touch with Lenin, Trotsky and Radek in Switzerland, and had adopted the programme of the Zimmerwald Congress. Both these parties were still largely heads without bodies, while the extremists were weakened by the imprisonment of Liebknecht in 1916. The Majority Socialists commanded the prestige and the organisation. But although the Russian revolution of March 1917 emboldened them, and at the International Socialist Conference at Stockholm in June 1917 they made a declaration against annexations and indemnities; and although the Emperor found it wise in his "Easter Message" of 1917 to promise a reform of the franchise, they might have been ignored had not Erzberger obtained and communicated to his colleagues of the Centre on July 6 a copy of Count Czernin's famous memoir in which he described Austria-Hungary as being on the verge of revolution, and victory as impossible.

Erzberger now propounded a resolution in favour of "peace by understanding," and the Centre and the Majority Socialists were definitely allied against the Imperialist aims of the Government and the Supreme Command. The latter were not yet ready for concessions; Bethmann Hollweg's successor, Michaelis, was their nominee. Only when Hertling succeeded him was a bill introduced which provided for a really democratic reform of the franchise; and the discussions on it outlasted the fall of the Empire. Certain concessions were, however, introduced; a minor electoral reform was carried on June 8 1918.

The Bolshevik revolution in Russia (Nov. 1917) widened the split in the Socialist camp. The Majority condemned Bolshevik methods in Russia, the Independent Socialists looked on them with much sympathy, and their following was strongly reinforced by unorganised labour, whose imagination was fired by the example of Russia and by the prisoners of war who began to return after the peace of Brest-Litovsk. The Spartacists were frankly out for the establishment of a dictatorship of the proletariat in Germany, and began to organise with the arms and money which the Russian agitators transmitted to them. All three groups, however, were alike emboldened by events in Russia; in Jan. and Feb. 1918 a series of munition strikes broke out in Germany which almost reached the scale of a revolution, their extent and order showing the vast power of the Majority Socialists, who, although they had not organised the strike, put themselves at its head to gain control of it.

The great munitions strikes, which were largely spontaneous, were symptomatic of an almost universal state of feeling. The almost intolerable strain and privations resulting from nearly four years of continuous war and blockade had affected practically the whole population. Hardly one man in a hundred saw in events in Russia the triumph of a new doctrine, the establishment of a new system, but those were innumerable who saw in it the end of a tyranny, of a driving of men beyond their powers, above all, of war and slaughter. The active policy of the Socialist leaders drew its strength from the great passivity of the over-driven masses; revolution was becoming the line of least resistance. The main motive in the German revolution, which substituted a Socialist for a monarchical Government, was to be anything but Socialist; it was the longing of workman and soldier to relieve themselves of the tyranny of the State in army and workshop.

In Sept. 1918 the general staff at last admitted the probability of defeat, and the Government prepared to make concessions to the moderates. Prince Max of Baden, the new Chancellor, asked the Majority Socialists to enter the Government. They made their acceptance conditional on far-reaching internal reforms; the liberation of Belgium; the evacuation of all occupied territory; and the abandonment of the treaties of Brest-Litovsk and Bucharest. Prince Max accepted the conditions, and took Scheidemann and Gustav Bauer, and later other Majority Socialists, into his Cabinet. The party then appealed to the Independents to re-unite; but the latter, who rejected all co-operation with bourgeois parties and demanded an immediate peace, refused brusquely.

The Outbreak of Revolution.—Prince Max filled the remainder of his Cabinet with liberals and democrats, including Erzberger. On Oct. 5 he propounded a programme containing a decided profession of democracy, with self-determination of nations. On Oct. 28, when Germany's allies had already failed her, he introduced a number of measures to democratise the Constitution and control the prerogatives of the Emperor, and especially to reduce the power of the military authorities. Meanwhile, however, Germany's own fighting forces had become infected. On Oct. 28 the fleet received orders to put out to sea "for manoeuvres." The crews, rightly suspecting that the real object was a last and desperate attack, refused to weigh anchor. Their ringleaders were arrested. On Nov. 5 a great meeting demanded their liberation. It was refused, and the demonstrators fired on. The next day the whole fleet was in uproar. There had been a naval mutiny in 1917, and a connection had been traced between the mutineers and the Independent leaders Haase and Dittmann. The situation was obviously critical. Noske, a Majority Socialist leader, was sent to Kiel to negotiate; he arrived to find a Sailors' Council in full control. He recommended that all their requests be granted, and remained in Kiel, where he was joined by Haase and Ledebour. Further Councils were formed. On the 6th the dock labourers in Hamburg revolted; a dictatorship of the proletariat was formed in Lübeck and demanded "immediate armistice and peace." Bremen joined on the same day; Hanover, Brunswick and Cologne on the 7th. The movement spread towards Berlin; revolutionary bodies took possession of Magdeburg, Leipzig and Dresden.

Thanks to the lamentable Socialist split, the whole of these movements were very confused. The Majority Socialists had still far the strongest organisation, but the movements in Northern Germany were largely spontaneous, the work of the unorganised proletariat. It was the outcome of a deep craving for peace and a reaction against authority. Many concerned in it followed the lead of the Independent Socialists, who were not compromised by their connection with the Government, many that of the Spartacists, whose leader Liebknecht had been released from prison and was conducting a violent extremist agitation. The Spartarcists, numerically the smallest group, had the great advantage of a fixed programme, although, an unattainable one.

The most urgent question, in view of Germany's defeat, was how far continuity with the previous régime should be preserved. The parties of the Centre and Left Centre had not in the main gone further than the idea of a constitutional republic; and the Emperor had subscribed to the Constitution of Oct. 28, and on Nov. 2 had declared that the old order was destroyed and that the Emperor was the "servant of the people." But this declaration was issued from Spa, whither William had fled on Oct. 29. The servant of the people had made an unfortunate beginning in sheltering himself from them behind the bayonets of his soldiers in a town on occupied foreign territory. His conduct disheartened the monarchists and thinned their ranks, besides making it almost impossible for his loyal adherents to concert their policy, with its object away at the safe end of a long telephone wire. The republican movement received a great impetus.

The Majority Socialists were anxious not to break with the bourgeois parties, which enjoyed the confidence of the peasants and middle classes and commanded practically all administrative talent; while the Independents believed that a complete break with the past would ensure Germany better conditions of armistice. The Majority Socialists, carried forward on the tide of events, moved almost daily further Left, since to stand still would have meant losing their adherents to the Independents. On Nov. 4 they made up their minds in favour of a republic; and on Nov. 7 the rapid march of events outside Berlin determined them to present an ultimatum to the Government, demanding the abdication of the Emperor and the Crown Prince, under threat of withdrawing their members from the Government and proclaiming a general strike. The Emperor was still debating whether he could not lead the army back to restore order at home. The new Quartermaster-General, Groener, and Hindenburg pronounced this impossible on Nov. 9. The Emperor therefore telegraphed his abdication as German Emperor. On the 10th he fled to Holland.

Proclamation of the Republic.—Events had outrun him. Prince Max had announced the abdication on the morning of the 9th. His telephone conversations with William had given him the impression that the latter abdicated both as German Emperor and King of Prussia, and he still hoped to save the throne to the dynasty; but republics had already been declared on the 8th in Munich and Brunswick. The general strike was proclaimed; and Prince Max formally appointed Ebert, the leader of the Majority Socialists, as his successor, and retired. Almost his last act was to order the troops not to shoot on the vast processions already filling the streets of Berlin.

The power had thus devolved on the Majority Socialists, who made great efforts at once to preserve order—for which the collaboration of bourgeois parties was necessary—and to restore the unity of the Labour front. In Bavaria and some of the smaller states—every state in Germany, without an exception, was proclaiming the republic and forming more or less revolutionary Governments—this was effected without friction. In Berlin and the Government of the Reich it was more difficult. The Independent Socialists agreed to enter a Government, on condition that the Cabinet be purely Socialist. The heads of non-political ministries were allowed to belong to other parties, but each was "controlled" by a Majority and an Independent Socialist. The Government proper entitled itself a "Council of Commissioners of the People" and was composed of Ebert, Scheidemann and Landsberg for the Majority Socialists and Haase, Dittmann and Barth for the Independents. It exercised dictatorial powers. Scheidemann proclaimed the republic from the buildings of the Reichstag on Nov. 9. The new Government hurriedly passed a series of decrees abolishing the state of siege, with the various restrictions on freedom in force and proclaiming a general amnesty, but affirming the right to private property. Its chief task, however, was to conclude the Armistice; and Erzberger, who had remained in office as Secretary of State, had on behalf of the German Govt. received the conditions of Armistice from the Allies in the Forest of Compiègne on Nov. 8. The conditions made the resumption of hostilities by Germany impossible. As President Wilson had demanded, they laid down the evacuation of the left bank of the Rhine, the occupation of the bridgeheads of Cologne, Mainz and Coblenz, the restitution of prisoners of war without reciprocity and the continuance of the blockade. An answer was required by Nov. 11, and on that morning the Government was obliged to accept the terms without modification. At the same time they asked that peace negotiations should be initiated.

The Struggle Against the Extreme Left.—The severity of the terms was a blow to the Moderates and encouraged the extreme Left. Workmen's and soldiers' councils were already springing into existence everywhere; a last order of the Supreme Command had been to allow their formation unimpeded. Some were quite spontaneous, others organised by the Independents and Spartacists. Liebknecht had refused a generous offer to join the Government, and he and Rosa Luxemburg, assisted by Radek, representing Bolshevik Russia, worked furiously to proclaim a Soviet dictatorship on the spot. The Majority Socialists, on the other hand, considered themselves only mandatories till the real will of the people should have been ascertained by a Constituent Assembly. It was a struggle between dictatorship and democracy, and the issue hung in the balance. On Dec. 1 a "National Executive Committee of Workmen's and Soldiers' Councils" was formed under the Independent Daümig. The extremists in it regarded it as the supreme authority of Germany, which, since the Councils system *ipso facto* excludes the bourgeoisie, involved the dictatorship of the proletariat. On Dec. 16 the Committee met in Berlin. After a stormy debate lasting three days, the views of the Majority Socialists prevailed. The powers of the Committee were limited to summoning and dissolving the Council of Representatives, which received both executive and legislative powers. Elections for a Constituent Assembly to determine the future form of the German State were fixed for Jan. 19. The Independents condemned this decision as "social treachery," and a few days later the Spartacists appealed to arms. The Council called out troops against them, defeating the Spartacists, after heavy fighting, on Dec. 24. The Independents, in consequence, seceded from the Government on Dec. 29.

The Spartacists, who had adopted the name of "Communist Party of Germany" on Jan. 1 1919, prepared to renew the struggle. Meanwhile, however, Noske, who had been appointed Minister of National Defence, had hurriedly organised a force which again defeated the Spartacists after fighting which lasted from Jan. 5–13. Liebknecht and Rosa Luxemburg were arrested and murdered by their escorts, apparently in cold blood. During the next few months, Noske was probably the most powerful man in Germany. He was entirely ruthless. "Somebody," he remarked "must be the bloodhound." Till now, the change of system had been almost bloodless, and had indeed been accomplished with remarkable smoothness. No member of a ruling house was injured, some indeed were genuinely regretted by their subjects. The administration continued to function; the soldiers dispersed to their homes in order, largely thanks to the irreproachable conduct of Hindenburg. The Spartacists alone appealed to arms; and it is probable that in putting them down without mercy, Noske saved his country from much anarchy. But he did it by dangerous methods—although, indeed, these were the only methods open to him; he employed the old corps of officers to serve a republic which most of them loved but little. Thus only a few weeks after the revolution, officers of the former army were appearing as saviours of society against Socialists; and a revival of German militarism so obnoxious both to the Allies and to liberal and Socialist Germany was thus provoked.

The Constituent Assembly and the Treaty of Versailles.—The non-Socialist parties reorganised hurriedly. The Conservatives founded the German National People's party (Deutschnationale Volkspartei) and announced their readiness to co-operate in "any form of Government in which justice and order held sway." Certain of the National Liberals under Stresemann formed the German People's party. The German Democratic party represented the middle-class electors, but was largely an organisation of leaders, with less backing from the electorate. The Centre styled itself the Christian Democratic People's party. The elections for the Constituent Assembly on Jan. 19 gave the Majority Socialists 163 votes, the Independent Socialists 22, the German Nationalists 44, the German People's party 14, the Centre 91, the Democrats, with the Peasants' League, 81. The Communists abstained from voting. The National Assembly opened its sitting in Weimar on Feb. 6. The Independents refused to enter a coalition with non-Socialist parties; a coalition was therefore formed of the Majority Socialists, the Centre and the Democrats. Scheidemann became Chancellor; and Ebert was elected President of the Reich. A chief task of the Constituent Assembly was the elaboration of the Constitution, which was proclaimed on Aug. 11 1919. Elections in the principal states took place shortly after those for the Constituent Assembly. In Prussia the results were very similar to those for the Reich, Berlin and the industrial districts voting strongly Socialist. In Saxony the two Socialist parties had a majority over all others combined. In Bavaria, on the other hand, the clerical "Christian People's party" formed the strongest group.

The spring of 1919 was accompanied by continued trouble from the Left. The Berlin Spartacists made a fresh attempt to set up a Soviet Govt. in March. It decreed a general strike throughout Germany, which reached considerable dimensions in Berlin. It was quelled with bloodshed in Berlin, Halle, Leipzig, Stuttgart, Hamburg and other cities. In Bavaria the Minister President, an Independent Socialist, Kurt Eisner, was murdered by a Nationalist officer. A violent struggle ensued, and a Soviet Republic was proclaimed in Munich and ruled there till May 1. Much of this unrest was due to the uncontrollable effects of the aftermath of the War, the continuance of the blockade, universal underfeeding and unemployment; some to foreign agitation and some to irresponsibility. The Weimar coalition had undertaken a far harder task than that of opposition; but it struggled manfully to preserve the unity of Germany, to prevent bloodshed and, by disarming and respecting the Armistice conditions, to allow the Allies no excuse for applying sanctions. Exaggerated rumours were current as to the prevalence of democratic feeling and brotherly love in Great Britain and elsewhere, and the Government hoped that the peace terms, when they came, would strengthen their hand. The publication of the terms aroused deep consternation in Germany. Scheidemann resigned, saying "let the hand wither that signs this treaty." The Democrats left the Government. The Majority Socialists and Catholic Centre alone, and they with dissentient voices, agreed to take the responsibility of signing, under threat of the continuance of blockade, an Allied march into Germany and possibly the loss of the country's unity. Germany signed the Treaty of Versailles on June 28 1919 (*see* VERSAILLES, TREATY OF), the National Assembly giving its assent to the signature on July 9 by 208 votes to 115.

The Policy of Fulfilment.—Even while signing Germany refused to admit the sole responsibility for the War, and made every effort to prove by history that the charge was unjust, in the hope that this would lead to a revision of the treaty. The Government hoped and long believed that such a revision would come. Immediately after the ratification of the treaty, on Jan. 10 1920, President Ebert circulated a message that "we shall honestly endeavour to fulfil our engagements towards the Entente according to the Peace Treaty, but if there are clauses which prove to be absolutely unrealisable, we must hope that the Entente will understand this and be able to meet us in our difficulties."

For the time, however, the Government saw no course but to make the best of a bad job, and meanwhile strengthen republican and democratic elements at home. Its position was dangerous. The extreme Left had relapsed into comparative quiescence after the failure of the spring disturbances, but the opposition of the Right now began to rally. They saw that Great Britain and America had favoured more moderate terms in the Treaty of Versailles, but that the die had really been cast against them by the presence of the great French Army. They declared that Germany had only been forced to accept the treaty by her own action in disarming; that the treaty was imposed by *force majeure* and involved no moral obligation; that any attempt to fulfil its terms was high treason; and that the duty of a patriotic German was sabotage of the treaty, to resist disarmament, indeed to re-arm and to repudiate the treaty at the earliest moment when Germany's military power allowed it. Anyone connected with the "policy of fulfilment" was a traitor, and in the views of the extreme secret organisations which rapidly sprang into being, it was a patriotic duty to murder such a person. The advocacy of assassination, disguised as patriotism, became common; and was responsible for the murder, first of Erzberger, then of Rathenau.

Owing to the number of Jews among the Democratic and especially Socialist politicians, this Nationalist agitation was also preached as the struggle of the pure-bred German against the "hidden hand" of Jewry. Finally, and in reality most essentially, it soon took the form of a conflict of Social Democracy against the anti-Socialist forces of the rural districts and capitalism. Unfortunately for the Socialists, they had been obliged to take almost the sole responsibility for signing the treaty; although refusal to sign had been out of the question. The association of Socialism with national treachery was thus as easy as it was unjust. The industrialists financed the Nationalist movement heavily; the influence of the Roman Catholic Church was generally anti-Socialist and no doubt helped to detach from Socialism the peasants and small tradesmen whose republican sympathies had led them into the enemy camp.

In the autumn the National Assembly returned to Berlin. The Democrats re-entered the Cabinet. The Right was already agitating for new general elections, on the ground that the Constituent Assembly had finished its task by passing the Constitution. The demand was unwelcome to the Social Democrats, who were losing ground in the constituencies; and they hastened to pass what legislation they could. The eight-hour day had already been decreed. A bill, providing for the formation of Works Councils, was now introduced. A Socialisation law laid down in principle the transference of the whole mining industry to state ownership; but the committees of inquiry had not finished their investigations as to how this was to be done before the opportunity passed. Moreover, the fear that the Allied and Associated Powers might take over the nationalised properties acted as a deterrent on the Socialists. Erzberger, as Minister of Finance, introduced some drastic measures of taxation on War increases of income and an emergency contribution which contemplated the sequestration of a considerable percentage of private fortunes. (*See* INDUSTRIAL RELATIONS; WORKS COUNCILS.)

Reactionary and Communist Outbreaks.—On Jan. 10 1920 the Treaty of Versailles came into force. Very soon afterward Germany had to face her first and most serious attempt at a monarchist reaction. What is known as the *Kapp Putsch* was short-lived, and in some aspects almost ridiculous; but it was inevitable that it should be made, and the fact that it failed was momentous. Only now was the German republic firmly established and the unsettled elements left stranded by the end of the War were forced to see that the new order was not merely provisional. Henceforward, gradually, and with an ill-will which is not incomprehensible considering their circumstance and traditions, they adapted themselves and began to look on the new Republican Reich as an established fact. The movers in the *Kapp Putsch* were the old officers who, their occupation gone, comprised a dangerous and unabsorbed element, which at this moment was reinforced by the return of General von der Goltz's formations from the Baltic States. The treaty had provided for the reduction of Germany's army to 100,000 by March 31 1920. This reduction had not been made. Germany desired permission to keep a permanent force of 200,000; but the Allies granted only a fur-er grace of three months in which to complete the full reduction. The officers were faced with starvation and ready for any lventure. Kapp, a founder of the "Vaterlandspartei" seized e pretext to agitate against Ebert's position as unconstitutional. n March 13 Kapp, Von Lüttwitz, Erhardt and Colonel Bauer, rmerly Ludendorff's chief of staff, seized the public buildings Berlin with the aid of the marine troops quartered at Döberitz, nd proclaimed a "government of order, liberty and action" nsisting mainly of themselves. The real Government fled to resden and thence to Stuttgart, the Socialists of Berlin proaimed a general strike. The movement collapsed in a few days. ne leaders alone were punished, but most of them made their cape.

The strike had been completely successful; but it soon got out hand. The threat of a reaction infuriated the workmen; Rusan propaganda accused the Majority Socialists of complicity. nstead of returning to work, the workmen formed Soviets. The ommunist element had long been secretly organising a Red rmy. It now came into action in many parts of Germany. In eipzig the Government had to use aeroplanes against the city. Berlin, Württemberg and Bavaria the troops put down the oters easily, but in the Saxon Vogtland a Communist government aintained power for some weeks. In the Ruhr a Red Army 0,000 strong conducted regular operations. This was a demilirised zone, into which German troops beyond a small permaent garrison might not enter; and when, after some hesitation, force of the Reichswehr actually entered the zone, French oops immediately marched in and occupied Frankfurt, armstadt and Homburg, remaining until May 17, by which ate the German troops had left.

Reorganisation of the Reichswehr.—As a sequel to this incident oske retired. His place was taken by the Bavarian Democrat essler, who together with General von Seeckt reorganised e Reichswehr. Many reactionary elements were eliminated om the Reichswehr (and simultaneously from the civil rvice), and it was henceforward a sufficiently trustworthy m of the civil government, although strongly conservave in feeling. Von Seeckt engaged in a prolonged if unacknowllged duel with the Inter-Allied Commissions of Control, which mained in the country for some years. Technically, few viotions of the treaty were proved. Great masses of war material ere actually surrendered and destroyed; only in July 1920 as Germany admittedly and demonstrably in arrears in this spect. On the other hand, it is scarcely denied that much mained concealed; that a very high proportion of the men of ilitary age and youths of Germany received what was military aining in all but name from their respective political party oranisations; that Germany was at no time without the nucleus of a ighly-trained army, and could at any time have put into the eld a formidable force; while her rifles and artillery were short, er chemists and scientists were working hard to discover new ffensive and defensive methods which the Treaty of Versailles ad not anticipated.

The First Reichstag.—After the collapse of the Communist sing, the National Assembly considered its work as finished. The ections for the first Reichstag (June 6 1920) followed hard on ose stormy events. The moderates of each wing feared the iolence of the other, and voted in self defence for their own xtremists. The Independent Socialists increased their votes o 81, the German People's party to 62, the German Nationals to 6. The Democrats were reduced to 45, the Majority Socialists o 112, the Centre to 70.

To avert the danger from the left, the People's party agreed o enter a coalition with the Centre and the Democrats. The Iajority Socialists supported the Government without entering . Herr Fehrenbach became Premier, Dr. Wirth Minister of inance and Dr. Simons Foreign Minister. The Government ollowed the policy of its predecessor. Almost its first action as to meet the Allies at Spa (July 5), a somewhat stormy eeting, chiefly concerned—outside the question of German oal-deliveries and the Inter-Allied arrangements regarding e distribution of reparations—with Germany's failure to disarm. During the remainder of the year, however, Germany enjoyed comparative quiet, and really began to disarm. A number of minor questions arising out of the Peace Treaty were settled during this period. The plebiscites in Schleswig (*q.v.*) had been held on Feb. 10 and March 14; those in Eupen and Malmédy (*see* EUPEN) on July 24; those in East and West Prussia on July 11. The only important territorial arrangement outstanding was that of Upper Silesia.

The question of the trial and punishment of the "war criminals" aroused much ill-feeling. Holland's refusal in Jan., Feb. and March 1920 to extradite the ex-Emperor William probably robbed international law of many interesting decisions. The Allies had demanded the arrest and delivery of many hundreds of war criminals; but in face of German protests, the Allies agreed (Feb. 16 1920) to allow trial before German Courts. Twelve persons were finally tried at Leipzig (May 23—July 16 1921), six being convicted.

The year 1921 saw renewed trouble. A militia known as the Einwohnerwehr had been organised in Bavaria, and Von Kahr, the Bavarian Premier, declared himself unable to dissolve it in view of the Bolshevik danger. Already all the elements of reaction were concentrating in Bavaria. Von Escherich, the prime mover in the Einwohnerwehr, had also formed a second organisation, the "Orgesch" (Organisation Escherich) obscurely connected with the Einwohnerwehr but receiving no official recognition. The Orgesch was spreading throughout Germany and assuming the proportions of a secret army, while the Government professed itself unable to control it in view of its own weakness. The Allied ultimatum of May 5 1921 at last decided Von Kahr, the Bavarian Premier, nominally to disband the Einwohnerwehr under threat of an occupation of the Ruhr.

The Bolshevik danger was real enough. The Majority Socialists had adhered to the Second International at Geneva in Aug. 1920; the Independents had joined the Third International (a minority dissenting) and coalesced with the Communists as the "United Communist party of Germany" (V.K.P.D.). A small and even more radical group formed a section of the Fourth International as the "Communist Labour Part of Germany" (K.A.P.D.). In March 1921 Moscow considered Germany "ripe for revolution" and a widespread rising broke out in Central Germany. The V.K.P.D. maintained a Communist régime in Halle, Mansfeld and Eisleben for several weeks. The insurrection, which spread as far as Hamburg, was put down with great difficulty.

The Reparations Problem.—Meanwhile the question of reparations was assuming the overwhelming importance which it was to retain for four years. Germany's financial situation was curious. Apart from the effects of war and blockade, she had been permanently weakened by the losses of large portions of territory. Nevertheless, her currency was low and her exports cheap, her territory unravaged, her population industrious. The middle-classes and officials were suffering severely, and districts such as Saxony, where industry depended on imported raw material and coal, were badly hit, so that in Germany there were now some 2,000,000 unemployed and at least 4,000,000 working half-time. In other places, however, where raw material was available, industry was flourishing. Notably the great industrial centres of Westphalia were reorganising and expanding most rapidly. Here Germany's chief wealth was concentrating and accumulating, especially in the hands of a few enormous combines, the most sensational of which was that which was founded and directed by Hugo Stinnes.

So long as complete uncertainty reigned as to what sum Germany would have to pay in reparations, the industrialists, who were strongly opposed to any "policy of fulfilment" made no attempt to relieve the financial distress of their country as a whole; they concentrated on maintaining their own prosperity and that of the districts under their own control, transferring capital abroad, speculating *à la baisse* on the mark, and paying their taxes in arrears and incompletely. It must be admitted that by their policy the industrialists did not only amass fortunes for themselves, but also saved the workmen in their concerns from otherwise inevitable unemployment, which would have had incalculable economic and political consequences. The Reichsbank, by granting the industrialists almost unlimited credit, encouraged this policy.

Enormous wealth had thus accumulated in Germany in a few private hands, while the Government was almost bankrupt. When the Allies, by Jan. 1921, had at last decided on the bill to be presented to Germany and its allotment among themselves, the difference between the wealth obviously present in Germany and that at the disposal of the Government was glaring. The essential problem was that of tapping the wealth of Westphalia. When the German Govt. declared the conditions of the Allied note of Jan. 29 1921 (*see* Reparations) impossible of fulfilment, and Dr. Simons, on a visit to London, was unable to come to any financial terms with the Allies, besides arousing their hostility by again repudiating Germany's war guilt, the Allies occupied Duisburg, Ruhrort and Düsseldorf on March 8 as "sanctions" and drew a customs cordon between occupied and unoccupied territory. It was this move which made possible the later occupation of the Ruhr district and opinion in Germany did not doubt that it was deliberately taken with a view to such later occupation.

The Fehrenbach Cabinet resigned. The Allies threatened to occupy the Ruhr and apply other sanctions. The "policy of fulfilment" became again a burning question; but in order "to save the German Reich and its unity, to save German territory from invasion and to retain German freedom" a new coalition Government under Wirth, composed of the Centre, the Majority Socialists and the Democrats was formed on May 10 and accepted the Allied ultimatum. Germany, by exertions which jeopardised the stability of the mark, paid the first milliard of gold marks on Aug. 31.

An early result of the Nationalist agitation against the "policy of fulfilment," which broke out with renewed violence, was the assassination of Erzberger (whose financial policy was particularly unpopular with the moneyed classes) on Aug. 25. The Independent Socialist Gartis was murdered in Munich, and the publicist Maximilian Harden wounded in Berlin, and an attempt made to poison Stresemann. A monarchist demonstration took place in Berlin; but although monarchist feeling was reviving, it lacked unity owing to the personal unpopularity of the members of the Hohenzollern family.

The Plebiscite in Upper Silesia.—The murder of Erzberger was followed by a further fall of the mark, which grew more pronounced in the autumn. The plebiscite in Upper Silesia had been taken on March 20, and had given 717,122 votes for Germany, 483,514 to Poland. The Polish High Commissioner, Korfanty, had thereupon raised an armed revolt, and the French troops stationed in the district were less successful in dealing with him than with the German defence force raised by General Hofer. As the Supreme Council was unable to agree on the fate of Upper Silesia, it turned the question over to the League of Nations, which awarded practically all the important industrial districts to Poland on grounds which were recondite in the eyes of many. This decision, which was taken in Oct., caused a crisis, more especially as it came at a moment when the "Reichswirtschaftsrat" had just evolved a plan under which the rich landowners and industrialists at last consented to make heavy sacrifices in order to stabilise the financial situation. These offers were now withdrawn.

The Second and Third Wirth Governments.—Wirth resigned, but formed a second Cabinet against the opposition of the extreme Right and Left. All other questions were now dominated by that of reparations, which in its turn brought fresh conflicts between Left and Right. The burden of reparations was being borne almost solely by the wage-earning and salaried classes, from whose pay the taxes were deducted on payment. As the fall of the mark accelerated, the proviso under which industry and agriculture were allowed to pay their taxes in arrears reduced their burdens to a trifle, while they were able to pay off debts and mortgages at a fraction of their real value. The reactionary agitation increased daily; but owing to emergency legislation passed in Aug. 1921 the year passed off without disturban In 1922, however, the state deficit increased enormously. T Government was obliged to beg for moratoria and to allow t Reparations Commission the right of scrutiny over Germa financial measures. On June 24 Rathenau, Germany's greate statesman, was murdered by Nationalists. He was the one ma in Germany who had shown himself capable of a positive polic In June 1921 he had come to a direct agreement with M. Lo cheur regarding the reconstruction of the devastated regions Northern France. On April 16 1922, as one of the German repr sentatives at the conference of Genoa, he had signed the Trea of Rapallo with Russia. The treaty had slightly eased Germany financial situation and had opened up a new field of activity her industry, but by proving her unwillingness to remain a c pher in foreign policy it deeply irritated the Allies.

In Aug. Poincaré came to the conclusion that Germa could only yield reparations if "productive pledges" we seized; that is, if the Allies actually took the Ruhr districts a managed them for their own profit. France's Allies were unwilli to consent to this, but the threat overshadowed the situatio The financial distress and continued fall of the mark made stabi sation the most urgent necessity. But the Allies rejected Ge many's suggestion to make this possible by reducing reparation the Reichsbank was unwilling to risk its last gold reserves; t Socialists refused to increase production by allowing hours labour to be lengthened, maintaining that the profit would go in the pockets of the capitalists. Thus Germany remained polit cally disunited.

On Sept. 24 1922 the Majority Socialists, who had revise their programme at Görlitz on Sept. 18 1921, re-united with t Independents.[1] As a counterpoise, the moderate bourgeois pa ties formed a "working agreement" with the People's Part The Social Democrats having refused to enter a Governme with the People's Party, Dr. Wirth resigned and on Nov. 23 192 formed a minority "business government" of middle-class re resentatives and permanent officials. It carried on the financi policy of its predecessor, stabilisation through reduction of rep rations.

The Occupation of the Ruhr.—On Dec. 26 1922 and Jan. 9 192 the Reparations Commission, the British member dissenting, d clared an "intentional default" on the part of Germany. O Jan. 11 French and Belgian troops occupied the territory of th Ruhr. The history of this struggle is told elsewhere (*see* Ruh The population of the Ruhr adopted an attitude of "passive r sistance" which was supported by the Government. For eig months the Government maintained as a charge on its financ the population which ordinarily yielded its chief source of reve nue. It could only meet this expenditure by unlimited inflatio which was aggravated by singularly incompetent administra tion of the Reichsbank. By June the mark was quoted at 150,00 to the dollar; on July 30 at 1,000,000; Nov. 20 at 4·2 billion Austria's financial collapse paled before conditions in German starvation for the working and middle-classes, mushroom fo tunes won by speculation, the rise of prices marked by a mult plication so that people entered a shop with a considerable sum i paper and found it too little to buy a crust of bread by the tim they reached the counter.

In view of the growing unrest, the Social Democrats agreed t enter a Government on a broad basis, with Stresemann, know to be a strong man, as Chancellor and Foreign Minister. Th "Grand Coalition" was at last formed in Aug. 1923. Hilferdin a Social Democrat, became Minister of Finance. An attempt t stabilise the currency under existing conditions broke down. O Sept. 26 the Government proclaimed the abandonment of passiv resistance in the Ruhr, and relieved itself of the financial expen iture involved. On the following day, it announced its inte tion to use all means to put down any attempt to create distur ances, and proclaimed martial law throughout the Reich.

---

[1] The United Socialists joined the Second International at th Congress of Hamburg May 21-7, 1923, when the "2½ (Vienna International" of the German Independents, the Austrian Socia Democrats and the British I.L.P. ceased to exist (*see* Socialism).

Political Unrest.—The appalling financial catastrophe had pro-
ed a most dangerous political situation. In the Rhineland
l the Bavarian Palatinate (*see* RHINELAND), the French were
rking to create a separatist movement. In Bavaria proper the
tation was less artificial. There were two great movements in
varia. Von Kahr, who had been Premier in 1920 and 1921,
ed his power on the Bavarian People's party. He wished to
nsfer the "centre of gravity" of Germany to the Catholic
th, and while he denied any aim further than revising the
imar Constitution in the favour of federalism, he was an
wed monarchist—the Bavarian dynasty occupied a position
Bavaria little inferior to that which it had enjoyed up to 1918—
party had been compromised by revelations of their relations
h the French, and he had involved himself in various schemes
create a Catholic Danube monarchy of the South to include
ts of Austria. A second party was led by Hitler, an immi-
nt workman from Austria, and Gen. Ludendorff, supported by
nerous refugees from the Kapp Putsch. Its adherents styled
mselves "National Socialists" but were in fact not Socialists
ll. The programme was to "regenerate the Reich through
varia." These two groups were constantly intriguing with each
er and with various reactionary and Catholic parties outside
varia and outside Germany. A dangerous situation had been
ated in the summer of 1922, when Bavaria refused to recog-
the legislation and tribunals of the Reich. It was smoothed
r, and Von Knilling had since acted as Premier, with an un-
r policy. Throughout 1923 the agitation of Hitler's "Völ-
he" party grew so rapidly that a coup was almost daily expected,
ich would have been accompanied by military reaction in
rth Germany. The Government considered the monarchists
lesser danger; on Sept. 26 civil law was suspended in Bavaria,
Von Kahr appointed General Commissary with dictatorial
vers. He instantaneously consolidated his position by lower-
the price of beer.

he state of Saxony and Thuringia were no less disturbed. A
Bolshevik centre had been established in Dresden and the
mier, an extraordinary figure named Zeigner, was ruling at
head of a coalition of Communists and Left Wing Socialists.
ed Army had been formed, and was only waiting for a reac-
ary outbreak in Bavaria, which would give it the sympathy
the workmen in Berlin, to establish a Soviet Govt. and
terror. In addition, quite apart from the separatist move-
t, there were grave Communist disturbances among the un-
loyed in the Ruhr. The plans of the Third International,
ch was directing this movement, regarded Saxony only as a
mping off place" and envisaged a general rising with the
tre in West Germany. The Government had, however,
rched the offices of the Russian Trade Delegation in Berlin
May 3; and although relations between Germany and Russia
e in consequence very strained throughout the summer, the
man Govt. had obtained valuable information on the plans
he Communists.

he proclamation of martial law by the Government was an-
red by defiant demonstrations by all the malcontents and an
al outbreak by the Separatists in Düsseldorf on Sept. 30.
Saxon Finance Minister, Böttcher, called on the proletariat
rm. Fortunately, each side waited for the other to move
le the Government of the Reich passed through a fresh crisis.
he German People's party were alarmed at the presence in
Cabinet of Hilferding, who was known to be a champion of
onalisation. They desired legislation for increasing produc-
without regard to the eight-hour day, and that the Govern-
t should receive dictatorial powers to issue orders of this
re with the force of law without consulting the Reichstag. The
alists were determined to oppose any tampering with the
t-hour day. The parties finally agreed on the principle of a
w regulation of laws regarding hours of work, with retention
rinciple of the eight-hour day." The Stresemann Cabinet
reconstructed in early October. Hilferding left it, and Dr.
her became Finance Minister. The Cabinet received the de-
l emergency powers on Oct. 13. It was now able to deal suc-
fully with the Communists. The Military Commander in
Saxony called on Zeigner to repudiate Böttcher's speech. Zeigner refused; troops of the Reichswehr then entered Saxony on Oct. 22, forced Zeigner to resign and restored order. Other troops occupied Thuringia and disbanded the Red Army, and a rising in Hamburg was put down.

In Bavaria the military commander, Von Lossow, sided with the Bavarian Govt., refused Von Seeckt's order to resign, and allowed the Bavarian authorities to appoint him Provincial commander. The Bavarian Govt., in defiance of the law, exacted a special oath of allegiance from the Bavarian troops. Many officers of the Reichswehr openly sympathised with Ludendorff against the government of the Reich, and Hitler and Ludendorff were encouraged to believe their hour had come. On Nov. 8 they seized Von Kahr and Von Lossow and proclaimed a government, consisting of themselves. Von Kahr at first appeared to fall in with their plans and announced himself as "viceroy of the King of Bavaria." But as soon as he saw that the Reichswehr would act against the insurgents, he called in troops, which fired on the revolutionaries. Ludendorff fell on the pavement and shammed dead till all was over. His much-enduring reputation could not stand this strain.

His fellow conspirators were arrested, and the pricked bubble of the "Völkische" collapsed. In the following spring the chief participants were tried. Ludendorff was acquitted. Hitler and other leaders imprisoned. The trial aroused great excitement on both sides. The separatist movement in the occupied territory reached its climax about the same time. The "Rhineland Republic" was proclaimed at Aachen on Oct. 31; at Coblenz on Oct. 25; and in other Rhineland towns at the same time. The movement then gradually decayed, and had disappeared by Feb. 11 1924, except in the Bavarian Palatinate. The official birthday of this Government was Nov. 11, and French support of it was more than usually tenacious. It finally vanished at the end of Feb. 1924.

Financial Reconstruction.—This proved to be the climax of Germany's troubles; but her internal political situation was still uncertain. The Socialists withdrew their support from the Government on account of the different treatment of the insurgents in Saxony and in Bavaria. Stresemann failed to secure a fresh vote of confidence and a new emergency powers Act, and resigned on Nov. 23. On Dec. 1, Marx formed a minority "middle-class" Government with Stresemann as Foreign Minister and Luther as Minister of Finance. The Government received a new emergency powers Act to carry through the work of stabilisation and reconstruction during a limited period. By the appointed date (Feb. 15 1924) the budget was balanced by means of these emergency decrees. The first reduced the number of officials, readjusted taxation and ordained pre-payment of taxes. The second stabilised the mark, introducing a strictly limited issue of "Rentenmarks," each equivalent to one billion paper marks, and limiting credits. The third carried through the principle of valorisation of public and private debts which had been inaugurated before the inflation period set in. At the same time the Ruhr industries reached an agreement with the M.I.C.U.M. (*Mission interalliée de contrôle des usines et des mines*) regarding deliveries in kind on reparation account which formed the transition to a new settlement of reparation obligations.

The Dawes Plan.—On Jan. 14 1924 the Committee of Experts for the examination of Germany's capacity to pay met in Paris under Gen. Dawes. Its relations with Germany were not unhappy, and it frequently consulted Schacht, the new President of the Reichsbank. A British Labour Ministry entered office on Jan. 22, and Poincaré gave way to Herriot in France in May. Germany's internal and foreign position now improved very rapidly. On Feb. 5 the British Prime Minister expressed the hope that Germany would join the League of Nations. Soon after, a German Ambassador was appointed to France, for the first time since the War. Von Kahr and Von Lossow retired on Feb. 18, and the powers of the Bavarian general commissariat came to an end. The state of siege in Saxony and Thuringia lapsed on March 1. The Dawes Plan (*see* REPARATIONS) was accepted in principle by the Governments of the Reich and of the Territories on April

14, and by the Association of Industrialists on April 24; but the new elections for the Reichstag had been fixed for May 4, and were fought almost solely on the Dawes Plan as an issue.

In view of the great distress following the sudden deflation, restriction of credit and rise of prices, the extreme parties of both wings gained votes at the elections. All the Government parties lost heavily, while the Communists secured 62 votes, the "Völkische" 32 and the German Nationals 96. Nevertheless a vote of non-confidence in the old Ministry, which had remained in office, was defeated on June 6 by 239 votes to 194 and Marx and Stresemann left for London on Aug. 4 as the representatives of Germany. The decisions of the Conference of London were initialled on Aug. 16. They provided for the restoration of Germany's fiscal and economic unity; the military evacuation of the Ruhr by Aug. 16 1925 (by separate agreement between Marx and Herriot); the issue of a banker's loan to Germany of £40,000,000; and the continuance of reparations deliveries in hand. The Dawes scheme was to come into full operation by Oct. 5.

The Government was just able to carry the acceptance of the Dawes Plan. The German Nationalists consented to allow its members to vote independently. The essential laws (the denationalisation of the state railways, the Bank law, the private Banknote law, the law liquidating the Rentenbank and the coinage law) were passed and the agreement on the Dawes Plan was ratified on Aug. 29. The laws in question came into force on Oct. 12.

The complaisancy of the Nationalists had been bought at a considerable price. They regarded their concessions purely as business arrangements, as facilitating the influx of foreign capital and reducing the danger of fresh Communist disturbances. But they were growing ever less ready to accept Germany's position as an outcast; and demanded from Stresemann a statement repudiating Germany's war guilt, as well as a place in the Ministry. A statement in accordance with the first demand was made in the Reichstag, while in the autumn Stresemann began to sound the ground regarding Germany's entry into the League of Nations. On Sept. 23 the Cabinet arrived at a decision in principle to seek the speedy entry of Germany into the League. As, however, the British and French Govts. could not give a definite answer to the memorandum which she addressed to them on Sept. 29 asking "whether the guarantees requisite for an application for membership and the status of Germany within the League, and also other definite and inseparable questions, were forthcoming," the matter was left temporarily in suspense.

The second Nationalist condition led to the dissolution of the Reichstag on Oct. 20, as it proved impossible to induce the Social Democrats and Nationalists to sit together. The general elections were held on Dec. 7. But by this time the general situation had grown much easier. The Régie railways and mines in the west, and the customs, were again in German hands. The customs barrier between occupied and unoccupied territory had vanished. The M.I.C.U.M. agreement had become void. There were general symptoms of a revival in trade. The extremists lost votes again; the Communists were reduced to 45, the "Völkische" to 14, while the Socialists rose to 131. The numerous parties of the Right Centre formed the strongest Parliamentary group. A Luther Cabinet, including four German Nationalists, held a precarious tenure in which it endeavoured to compromise between the demands of various interests. Protective tariffs for agriculture were introduced, the sales tax lowered, restrictions on deals in foreign currency for commercial purposes abolished, official salaries raised, the goods tariff and certain postal dues reduced, the tax-free limit of income raised to 60 marks a month, and old claims valorised in July 1925 by a law of the Reich. The middle-class Government of the Reich, was, however, confronted by the incessant hostility of the Prussian Govt., where the parties of the Weimar coalition were in power. Although her Parliament was a mass of small, jealous parties, Germany at large was divided into two broad groups of the Right and Left which attacked each other bitterly. Each raked up a series of scandals against the other; this unsavoury process culminated when a judge, in his summing up on a small case, stated that the President of the Reich had been guilty of high treason to the Reich by his part in directing the munitions strike in 1918. The Nation ist Press broke out into violent invective against Ebert; t whole legend of the "stab in the back" was revived. The ca paign was the more cruel that it was directed against a sick m He died after an operation on Feb. 28 1925. Few men h served their country so well.

Von Hindenburg's Presidency.—Seven parties chose to forward candidates for Ebert's vacant post, and these includ such names as Ludendorff and the Communist Thälmann. T first poll gave no candidate a sufficient majority. The Right th united to bring Hindenburg forward; the Left proposed Ma the Communists stood apart.

On April 26 Hindenburg was elected by 14,639,000 vo against 13,740,000 cast for Marx and 4,900,000 for Thälma Many Socialist votes had been withheld from Marx on accou of his Catholic tenets. Hindenburg's election aroused gre apprehension outside Germany, but in point of fact the field marshal preserved his dignity and his common sense perfectly as he had throughout the War and the revolution.

Foreign Relations.—With the balance thus held evenly tween Left and Right, the extremists discredited and the uni of the Reich established, the interest in German politics w now almost confined to foreign affairs. If little has been sa hitherto on this topic, it is because the course of events in 19 had assigned Germany an almost purely passive rôle. Of all h old friends or sympathisers, the only one which did not diso her in her defeat (if we except the small minority of die-ha generals in other defeated countries who dreamed of reversi the results of the War with fantastically inadequate mea was the little republic of Austria. The peace treaties forba the union of Germany and Austria. The decision was a bitt one for Austria, but hardly awoke equal sorrow in Germa Not only was Austria economically a heavily passive factor, the inclusion of her would have made it impossible to centra the Reich as was done by the Weimar Constitution, and t constitution would certainly have to be revised should Aust join Germany at some later date. For the rest, Allied a Associated Powers of older or more recent standing surround Germany as soon as the Armistice was signed.

With the Treaty of Versailles, which assigned the whole gu of the War to Germany, was incorporated the Covenant of League of Nations, which built up a great structure for maintenance of the peace of Europe, which Germany was invited to join. At first, indeed, she showed no anxiety to j Hostility to the League was almost universal owing to its as ciation with the Treaty of Versailles which even the advoca of the "policy of fulfilment" denounced as unjust in ma respects. The feeling was aggravated by doubts as to the imp tiality of the League's administration of the Saar basin a reached its climax when the decision of the Council of the Leag sanctioned arrangements in Upper Silesia which German opini resented violently. Nor was it confined to the Nationali Soviet Russia repudiated the League as a capitalist institut The German Communists followed the lead of Moscow, a the Socialists saw far more hope in a revival of the Internatio

After the first passions had cooled, Germany began to d tinguish between the various territorial provisions of the Trea of Versailles. The cessions to Denmark and Czechoslovak aroused little resentment; those to Belgium were small. T justice of the loss of parts of Alsace-Lorraine was not grea disputed. The three most important questions remained th of the Rhineland, of the frontier with Poland and of the Germ colonies.

The problem of Germany's western frontier differed fr others, both by its urgent economic importance and by the fa that Germany could claim that here she was only defending h rights within the treaty. She contended that the occupation the Ruhr was illegal, but so long as the threat of it, or its act ality, was not removed, it was impossible for her to initiate active policy; it was equally unthinkable for either party th Germany and France could meet as colleagues within the Cou cil of the League of Nations.

Thus up to 1924 Germany's foreign policy was almost entirely ensive. A number of minor treaties and agreements, mainly commercial character, were concluded; the most important ng the Treaty of Arbitration with Switzerland (Dec. 3 1921). t the only treaty of outstanding importance was that con- ded with Russia on April 16 1922. The text of this Treaty of pallo (*q.v.*) was not in itself such as to justify the protests h which it was greeted. These were rather due to the fear at the treaty contained secret clauses of a political nature, d especially clauses aimed against the integrity of Poland. e existence of such clauses was denied and, in fact, no polit- l developments could be traced as arising out of the treaty ring 1923 or 1924. It was a tactical error in so far as it increased ance's and Poland's nervous instinct; it certainly looked as ough Germany was drawing her conclusions from the Treaty Versailles with too much logic in associating herself with the cond Great Power which remained by mutual consent outside e European concert. Germany, however, claimed that she d no quarrel with Russia.

With the advent to power of M. Herriot in France in 1924 e situation changed. Moderate opinion in Germany was will- g to accept the permanent loss of Alsace-Lorraine in return r security on the demilitarised western frontiers. If Ger- any could become a member of the Council of the League, ere was some hope that readjustments on her eastern frontier ight prove possible at some future date, and this position ould also give her a chance of acquiring some day a colonial andate. The general improvement of relations between ance and Germany made their collaboration within the ague possible, while Germany was rapidly freeing herself om the restrictions imposed on her national sovereignty. sudden shock was given to the improving relations by the port of the Commission of Control on June 29, that Germany d not yet fulfilled the disarmament conditions, and that the logne zone could consequently not be evacuated in Jan. 1925. uring the year, however, the commission finished its work d the Cologne zone was evacuated on Jan. 31 1926. In July 25 the troops had been withdrawn from the Ruhr, and in g. from the districts occupied in 1921. The question of ving Germany her proper place in Europe now became gent.

The Pact of Locarno.—On March 4 1925 was published resemann's offer of a guarantee pact in respect of Germany's ntiers with France and Belgium and an undertaking to frain from military means of revision of her Polish frontier. his policy occupied the attention of Europe throughout 1925, d was finally embodied in the Pact of Locarno, after discus- ons between the European diplomats which lasted from Oct. 16. At Locarno Germany concluded a number of treaties hich practically guaranteed peace between her and her neigh- ours (*see* LOCARNO; SECURITY). The Pact was to come into fect on Germany's admission as a member of the Council of e League of Nations.

Stresemann's policy was not easily accepted in Germany. he widespread distrust of the League could not vanish in a y. The Nationalists objected violently to the permanent nunciation of Alsace and Lorraine involved in the Pact. But ey had not gained in strength so much as they had hoped ring 1925; in particular, Hindenburg's sensible attitude had eply disappointed them. The Pact was ratified on Nov. 27 25 and duly signed in London on Dec. 1. Luther's Cabinet en resigned, but after a prolonged crisis Luther formed a esh minority Cabinet of the Centre on Jan. 19 1926. The Social- ts promised him their support on condition that he pursued a publican policy and carried out the terms of Locarno. The ationalists opened a violent campaign against him, while feeling tween Right and Left was further embittered by revelations garding the naval mutiny of 1918.

It was the more disastrous that, when Germany's application r admission came before the League of Nations in March 1926, razil vetoed her admission unless she herself were also given seat on the Council. Speaking in the Reichstag, on March 22, Stresemann declared that Germany had received "moral rehabilitation" in Geneva, and that the policy of Locarno must not be allowed to lapse. Most of the German parties agreed to support him. The Nationalist spokesman found it easy to revile the League and Germany's attempts at reconciliation.

The Russo-German Treaty, April 24 1926.—Considerable excitement was aroused shortly after, when it was announced that Germany and Russia were again in negotiation for a treaty. This new treaty was signed in Berlin on April 24 1926 and published, together with an exchange of notes between the signatories (Stresemann and Krestinsky) on April 26. The basis of relations between Germany and Russia was stated to be the Treaty of Rapallo. The two Governments promised to remain in friendly touch with one another. Article 2 ran "Should one of the contracting parties in despite of its peaceful attitude be attacked by a third party or by several third parties the other contracting party will observe neutrality during the entire duration of the conflict." By Article 3 each party promised not to participate in any "economic or financial boycott" imposed on the other in times of war or peace. The treaty was to be valid for five years.

The third paragraph of the note for which Stresemann was responsible declared explicitly that "this fundamental attitude of German policy towards the U.S.S.R. cannot be adversely influenced by the loyal observation of the obligations (arising out of Articles 16 and 17 of the Covenant of the League and relating to the application of sanctions) which would come into existence for Germany as the consequence of her entry into the League of Nations," as such sanctions could only come into force if Russia were the aggressor, in Germany's own view, the views of other Powers not being binding on her. Whether Germany would take part in the application of sanctions at all, and to what extent, depended on the interpretation of the note of Dec. 1 1925 on the interpretation of Article 16 addressed to the German Govt. on the signature of the treaty complex of Locarno (the gist of this note being that no state could be held to undertakings manifestly beyond its powers). Germany maintained that this treaty was a necessary and proper adaptation of the situation under the Treaty of Rapallo to that created by the Pact of Locarno. Opinion in France and Czechoslovakia was inclined to question this view.[1]

---

[1] On May 5 the Luther Cabinet decided that a flag bearing the imperial colours, black, white and red, should be flown over the legations and missions of Germany, alongside with the black, red and gold of the Republic. The Democrats, dissatisfied with the attitude of Luther on this question, carried a motion against him on May 12 by 176 votes to 46. Herr Luther thereupon resigned, and Herr Marx succeeded him as Chancellor.

A serious difference of opinion arose over the proposal to confiscate the property of the former ruling houses, including the Hohenzollerns. Their large properties should, it was suggested, be devoted to benefiting the unemployed, war widows and other necessitous classes, while their castles and palaces should be used for welfare and educational purposes. The measure, which was opposed by President Hindenburg, was submitted to a referendum which took place on June 20. The total vote polled was 15,026,312, of which 14,441,590 were cast for confiscation, and 584,722 against. As, however, the constitution provides that more than one-half of the total votes—at that time 39,690,559—are necessary for success, the proposal failed. (ED. *E. B.*)

General Survey

The chronicler must not aspire to be a prophet. He may, however, reach a point from which he can survey the crowd of personalities and events grouped about him. How fares the Germany of 1925 in comparison with the Germany of 1910?

No such comparison can apply to economic life, since the inroads of the War have been too formidable and the consequences of the false economic policy which accompanied it could only gradually be surmounted. But it may be asserted that Germany has made a relatively rapid recovery from the unsound experiment of forming "vertical" trusts (liquidation of the Stinnes concern in Aug. 1925), and is striving by an energetic concentration of the operations of cognate industries to simplify the official organisation, to effect economies and to strengthen every enterprise included in the combine in its own capacity for output.[1] It is also a good sign that the influence of the most inventive and generally beneficent industry, the chemical industry, particularly the dyes branch (medicines, tropical therapeutics), has increased in industry as a whole.

Education and Justice.—As regards popular education, the arts and science, comparison is easier. For in these realms, where the War and revolution—which even in Germany party-life have strictly speaking only resulted in a change of nomenclature, produced a stagnation, a species of stupor, lasting indeed for years—development has been resumed at the point at which it broke off in 1914. One evil omen for the state is that popular confidence in the law has been shattered (in some cases through no fault of the judges) because during the period of inflation procedure in civil cases became farcical. There are others. The control of industry, which took the place of competition, benefited no one but the profiteers. In political trials the impartiality ofthe judges was often doubtful; in other trials, owing to the introduction of special courts, erroneous verdicts were laid to the charge of the law itself; young people only 14 or 15 years old, with unformed opinions, become members of contending political associations which do not subsist by their own strength but upon the funds of the adult party organisations. Finally, despite the diminished consumption of alcohol, popular amusements have become less harmless and "sociable." This is due in the great towns to the "revues," and in the medium-sized and smaller towns to the cinematograph, which before the most diverse audiences produces the same pieces and films, thereby destroying a healthy individual attitude towards art and recreation.

The relations between the German citizen and the state remain the same. He continues to regard himself as something distinct from the collective body. Just as during childhood he sees an enemy in the school and the teacher, so as a grown man he regards the State and the Government as an adversary rather than as something in which he himself bears a part and for which he is responsible. If "fiscal" morality is no worse, it is equally no better. The great problem of the schools has, moreover, not yet been solved, although attempts have been made in the Constitution itself and in a law of the Reich. It is sought to establish standard schools (Einheitsschule) providing an uniform education for the children of all classes up to the age of 10, and to give more instruction in German at the expense of the ancient tongues. But the problem of clerical influence in the school is still unsolved, and the process of converting purely scientific teaching into moral training for the young has been barely begun. The "movement of youth," which in the years before the War was making very great strides and led its members to the adoption of a simpler, more natural mode of life, to a greater readiness to help others, and, in many cases too, to a greater love of home, has split up into numerous sects. It has been ruined or impeded by the nee for earning a livelihood at an early age by work in the towns

In many respects, however, improvement is manifest. Afte the complete ruin of all means of communication in the las year of the War, order and punctuality have been restored withi the services with astonishing rapidity. The credit for this belongs to a great extent to the minister for transport, Groene The system of communications, so important an index for th modern state, is once more as efficient as before the War, an zealous efforts are being made to improve it. The police fee that they are there not so much to command as to render hel to the public. Many old officers serve the state honourably a members of the force. The great mass of the official class ha remained intact, and performs as much or more work for a salar which commands a purchasing power only equal to about hal that of pre-War salaries.

The Arts.—Parallel with the progress made in the chemica industry, in products demanding accuracy of workmanship an in the construction of machinery, taste and the sense of for have undergone a universal improvement. Photography an its application to open-air subjects produce excellent films Applied art, in which, however, German Austria holds the firs place, besides producing masterpieces in the luxury trades an in the form of efficient advertisements, has once more called genuine popular art into existence. Moreover, although in itsel unimportant it is of excellent omen that Germany to-day possesses not only toys but also children's picture-books (E. Kreidolf, Else Wenz, Wanda Ebel, Elsa Eisgruber) such as no othe country has. Since the death of Max Reger, Germany has n longer any composer to carry on the tale of her greatest creativ minds. The musical tradition is, however, kept alive by distinguished conductors and performers.

Germany has found a new and more serious rendering of musi than she possessed at the beginning of the century. In literatur the books that are read are of more significance than those tha are written. Side by side with Dostoievsky and the Scandinavians, the early German Romantics, Hölderlin and Novalis, are most read, but also Jean Paul, the object of enthusiastic admiration by the young. The writings alike of Goethe and Heine, treating of political and social topics, continue to exercise a powerful influence. The great national poet of German Switzerland, Jeremias Gotthelf, whom Ruskin admired, has been revived; and while young dramatists—Unruh, Toller, Brecht, Bronnen—in part powerfully influenced by Wedekind, espouse an exuberant "activism," Thomas Mann, taking up Theodore Fontane's subtle and genuinely realistic portrayal of North German society, has become, particularly by his last novel of contemporary life, *Der Zauberberg*, the undisputed master of prose narrative. The principal characters in this book, even if to some extent endowed with foreign traits, embody the whole of intellectual Germany in the same sense in which the spirit of English society lived and moved in the greatest novels of George Meredith. The clearest indication, however, of a turn for the better in Germany is given by town-planning and architecture. Even the terrible material stress of the War and post-War period has been unable to hold this in check. Examples may be found in Schumacher's town-planning scheme for Cologne, the railway station by Bonatz at Stuttgart and the Chile House in Hamburg.

(A. M.-B.)

IV. GERMANY'S NAVAL POLICY[2]

It has been frequently asserted that the creation of the German Navy was the main cause of the World War. Such an assertion implies not only that it was admittedly constructed on the right lines from a technical point of view—for no one would plunge into war for the sake of a negligible quantity—but also the admission that Germany's sea power was to be forcibly kept down. From the German standpoint a firm protest must be entered inst the view that as a political factor the German Navy con- uted a menace to foreign interests which could apparently be oved only by warlike methods.

---

[1] *E.g.*, the amalgamations effected since Feb. 1925: association of locomotive builders, of steelworks, of spirituous industries, the syndicate of Ruhr coal and mid-German brown-coal industries, of dealers in tubing, of wire-rolling mills, of dye industries, of aerial and shipping communications. In the autumn of 1925 an agreement was reached between the amalgamated German and the Belgian wire industries regulating the conditions of export on lines similar to the earlier Franco-German agreement respecting potash (*see* CARTELS).

[2] Admiral von Scheer's article is full of disputable propositions, but is published unchanged in accordance with the principle of the Thirteenth Edition of *The Encyclopædia Britannica*—to allow each nation to state its own case through recognized spokesmen.—Ed. *E.B.*

The tendency which emerges from the German naval laws, as ried into effect, is that of aiming only at the preservation of tifiable self-interests without encroaching too much on the ritime interests of other nations. "Defence is one of the most pressive and visible expressions of the State's will to independ- e." This pronouncement was made in 1922 by the Bundes- of Switzerland, a country which can in no wise be accused of rishing schemes for attacking its neighbours.

The preservation of independence is the predominant principle tate for civilised nations to whom the conception of liberty is ir very life element, and Germany cannot be reproached for lertaking the construction of a navy proportionate to her nomic requirements. For impotence at sea is an intolerable idition of weakness for a seafaring people, let their land ence be what it will. So much was made plain by the German- nish war of 1848–9, when Prussia, with ten times more inhabit s than Denmark, was forced to yield for lack of a fleet to se the Danish blockade of the Baltic ports, the economic losses tained by her sea-trade being greater than the advantages ob- nable by a land war against Denmark. It was with a view to djusting the situation that the Prussian Navy came into exist- ce. Founded in 1853, it passed in 1867 into the possession of North German federation, established after the separation of Habsburg dual monarchy from Germany.

This perfectly natural aspiration to escape from the German all state powerlessness and form a national state such as other ples (England and France) had long since secured for them- ves, had its origin in the progressive tendency of the age. The at state-making forces which gripped Europe in the beginning the 19th century after the Napoleonic wars of conquest were direct consequence of the overthrow, with British aid, of the ench domination of that continent.

Although Germany's expectations of securing State unity by y of reward for her share in the war of liberation were, for the e being, dashed by the ruling of the Vienna Congress of 1815, ambition, once aroused, left her no peace until she had se- ed the establishment of the Reich after the war of 1870–1 inst France, who stood in the way of a united German state. th the reannexation at the peace treaty of Alsace-Lorraine, Imperial provinces seized by Louis XIV., the German Em- e became—in Bismarck's words—saturated. Territorial ex- nsion in Europe was no part of the programme. Its efforts re directed towards keeping the peace in Europe so that its full ength might be devoted to building up the Reich. The produc- e capacity of the concentrated and greatly enlarged economic ea represented by the Reich grew to considerable importance voured by the progress of technical methods. International nmerce provided goods in bulk, in particular raw material an enormously expanding industry, and foodstuffs for the pidly increasing populations of the civilised states. Some of ese were utterly unable to supply the needs of life from their n resources, for example England, and also Germany, whose pulation of over 40,000,000 had risen within a few decades to er 60 millions.

The former large migration of Germany's surplus population overseas had now ceased. The German colonies by reason of eir inadequate development and geographical situation were suited to absorb any numbers worth considering. The growing lustrialisation of the country, on the other hand, offered new ssibilities of livelihood to the increasing population. As early the 'eighties, the annual emigration figures fell from 200,000 one-tenth of that figure. At the same time Germany's depend- ce on other countries increased, as may be seen from the trade urns. The relations of the new state structure with foreign ntries brought about the naval foundation-plan of 1873, ich aimed at creating a sea power of the second rank within the ce of 10 years. It was not until the close of the 19th century t the possibility of grave conflicts with other European Pow- arising out of trade competition became a serious factor.

England, with a technical equipment decades in advance of the German and a predominant position in world commerce, could watch the new competitor the more coolly, in that the opening up of the world offered so many new sources of trade that she alone could never control them. In addition, her established commercial connections, large mercantile marine and colossal colonial possessions placed her in so favourable a position that the development of new trading enterprise could not but be welcome. Germany became almost her best customer, and English exports to that country always exceeded in value the imports therefrom, to which, by her free trade principles, she opposed no obstacle prejudicial to mutual relations.

Now while the great territorial Powers, with their armies pretty evenly balanced, at a time when those armies count millions of men not lightly to be unleashed, it becomes more important to be able to throw the power of a big fleet into the scales. For the personnel needed is small, the country will not be directly plunged into suffering and the population is able to go about its daily task almost unheeding, while the silent pressure of sea power can exercise a definite influence. It was on these grounds that England's influential position in the European concert was founded.

Her rôle emerged the more clearly after two definite groups of powers had been formed in Europe, which, while approximately well balanced, persisted in a state of intent hostility. It therefore became necessary to keep England from throwing her weight against Germany. The construction of the German fleet was a political move against this possibility in that it would prevent a shifting of the European balance to the detriment of the Central Powers.

After the carrying out of the naval programme of 1873 the German Navy had, between 1883 and 1897, fallen completely behind and become obsolete. This stagnation set in with the appointment of General Caprivi to the admiralty. Under his rule coast defence filled the picture. Obsolete ironclads were not replaced because no one had any clear views on naval tactics. The same uncertainty prevailed in other navies continually experimenting to find the best type of battleship. This state of things was brought to an end by the English Admiralty with the Naval Defence Act of 1889.

In Germany, too, it was realised that a coast defence consisting of fortifications and torpedo boats was but an incomplete form of armament, useless for any far-ranging operations at sea. From the time of Kaiser Wilhelm II.'s accession (1888), efforts to modernise the fleet were made, though with small success. Four battleships of the "Brandenburg" class with 10,000 tons displacement were authorised by the Reichstag in 1890, but after that construction again came to a standstill. In spite, however, of the bad quality and insufficiency of building material during those years, the time was well spent in the navy, for definite tactical and strategical conclusions were reached as to the manner of using a fleet.

On these conclusions was based the first navy law introduced after Admiral Tirpitz's appointment as Secretary of State for the Imperial Navy in 1897. This committed the Government as to the number of ships and the Reichstag to the necessary expenditure. The programme was to be spread over six years at an expenditure of 409,000,000 marks (about £21,000,000 sterling). England had thus an advantage of almost 10 years, and was building onto an existing fleet, whereas Germany lacked a working basis.

According to the new scheme the number of ships demanded was based upon their tactical division into two squadrons, each containing eight battleships (16), in addition to which there were to be a fleet flag ship and two reserve battleships, making in all 19 battleships. Besides, 12 large and 30 small cruisers, to serve as scouts for the home battle fleet and for service abroad, were asked for. A navy law in this sense was passed in 1898. The preamble declared that "as opposed to the greater naval powers the battle fleet will have importance solely in sorties." This was evident, both from the limitation in the number of vessels and from the circumstance that 12 of the old battleships were to be included in the figure to be reached in the course of six years.

The conflict of battleships now came to the fore as the strategic task of the fleet. This alone, according to the teaching of naval history, was the means by which command of the sea could be maintained. The limitation of the said control to Germany's home waters, the Baltic and the North Sea, was imposed by the relative strength of the German Navy to other navies. For a time, it is true, Germany was influenced by the young French school, which set forth the destruction of the enemy's sea-trade as the main task of a navy, but the principles were not only never applied but in the end definitely rejected in favour of the decision to build a battle fleet.

Adherence to this decision was the principle underlying the further upbuilding of the German Fleet, a measure that could no longer be delayed in face of the developments in foreign politics at the turn of the century. England's attitude towards Germany had become definitely hostile. The Franco-Russian alliance was obviously directed against Germany, and the clash between France and England over the Fashoda incident was smoothed out of existence by England's vigorous action. The pressure exercised by England through her Fleet on this occasion might well be regarded as a hint of what Germany might expect one day, especially as her interests at sea were definitely on the up-grade owing to the increase in trade. A comparison of the figures showing the rate of this increase for the two countries affords convincing proof of the possibility of peaceful parallel development.

The total foreign trade returns (export and import) amounted in millions of marks (20·4 M.=£1) to:—

	1890	1900	1910	1912	1913
Great Britain	15,300	17,900	24,733	27,409·5	28,632·5
Germany	8,195	11,089	17,615	21,256·6	22,546·6

The increase over 20 years from 1890 to 1910 was thus 9,433 million marks for England and 9,420 for Germany. But the increase in England's population from 38,000,000 to 46,000,000 during the same period was only half that of Germany's, which rose from 50,000,000 to 66,000,000. In proportion to the population, the increase in England's trade returns was therefore twice that of Germany's.

The total foreign trade returns of the more important countries were as follows:—

	Milliard marks
In 1890 roughly	73
In 1900 roughly	92
In 1910 roughly	147
In 1912 roughly	169

Between 1890 and 1910 an increase of 100% is shown. Increase of population over the same period in England=20%. As these 20% achieved a trade increase of 62% there could hardly be any serious question of Germany's crowding out England.

In Germany, the growing volume of trade was more and more sea-borne trade; the maritime proportion became 70% of the whole. In view of this development Germany had necessarily to think of the better protection of her sea connections. Accordin after taking the first step (in 1897) of modernising her out date fleet, she took (in 1899) the second step of doubling battleship squadrons from two to four on the basis of the decla tion: "Germany must possess a battle fleet so strong that with it would involve even the mightiest naval power in peril such a kind as to jeopardise its own supremacy." Those who sist in regarding this extended naval programme and its basis a proof of hostility to English supremacy at sea have misund stood the development of Germany's economic position a ignored the change which had taken place in the internatio political situation.

At the time of the great colonial wars of the 17th and 1 centuries, England had to deal with only *one* sea-trade rival a time—Spain, Holland or France.[1] The commercial centre gravity in the course of centuries had been shifted by Englan historic interventions from Cadiz, Lisbon and Amsterdam to L don. But London was no longer all-important. New Yo Antwerp and Hamburg were centres also. The trend of circu stances was towards the establishment of a sort of internatio balance of power. A struggle between England and one of h commercial rivals for the possession of the world's mark would no doubt have ended in her favour, thanks to the ov whelming superiority of British sea power; but the remaini competitors for the world's trade would have taken advantage England in her inevitable exhaustion after victory to aim blo at her commerce which even she would have difficulty in repellin

No one will deny that Great Britain, with her divisions empire scattered all over the globe, with her leading position international trade, with her dependence upon oversea commu cations arising from her insular situation and extensive industri and finally with her strong hold on international commerce, h the right and the duty of maintaining a fleet considerably larg and more powerful than those of other nations. This suprema is ungrudgingly allowed her. But should it lead to the preve tion of free commercial competition, all the other nations inte ested in international commerce would presumably unite safeguard themselves. This is the idea which found expression the German navy law; in adopting it Germany only followed t example of other states.

The table below shows the battleships of over 10,000 to and armoured cruisers of over 5,000 tons, not more than 20 yea old, possessed by various countries in 1900.

1900	Germany		England		United States		France		Japan	
	No.	Displacement	No.	Displacement	No.	Displacement	No.	Displacement	No.	Displacement
Battleships	7	73,300	40	543,800	9	110,550	17	105,920	5	71,030
Armoured cruisers	1	10,690	10	75,580	2	19,270	5	35,910	3	29,720
Total	8	83,990	50	619,380	11	129,820	22	141,830	8	100,750

In 1910 the comparative strengths are shown by the following figures:—

1910	Germany		England		United States		France		Japan	
	No.	Displacement	No.	Displacement	No.	Displacement	No.	Displacement.	No.	Displacement
Battleships	28	360,990	56	859,990	29	451,320	16	207,430	12	174,630
Armoured cruisers	9	95,590	38	475,880	15	208,980	17	172,320	12	125,000
Total	37	456,580	94	1,335,870	44	660,300	33	379,750	24	299,630

With the respective strengths of the fleets thus distribute England had no need to fear that she would be ousted from h position; but it was necessary for Germany to protect hers against the eventuality of England's weight being thrown on th side of the group opposing the Central European Powers. Th England would supposedly risk little or nothing in so doing indicated in Churchill's slogan "Business as usual"[2] at th ning of the War; whether or not he was mistaken those in nd can best judge.

---

[1] In the 18th century and just after England usually had to figh France and Spain together, and had always to reckon with th probability of their combination.—Ed. *E.B.*

[2] This phrase was not Mr. Churchill's.—Ed. *E.B.*

e long duration of the War and the unexpected capacity for ance displayed by the Central Powers affected the tech- of the War, on sea as on land, to an extent that could not been foreseen. Submarines, flying and the use of gas are nd terrible phenomena of great possibilities, still in their cy. In future, technical power in these respects must play at a part that insular security will be a thing of the past. uestion whether a true insight into such changes in the con- s of power and security might have suggested a less light- ed view of the consequences of the War is not for discussion; neither can we discuss the possible results of a different e of English policy. None the less, one is tempted to imag- e reply of the Delphic Oracle if consulted by British states- efore entering into the War: “ If you cross the North Sea ill destroy a great empire ”—not the German empire only meant.

e growth of the fleet by no means represented merely mili- ivalry at sea; rather ought that development to be regarded insurance premium for the great increase in trade interests g the same period, and as one aspect of a general forward ment in all countries chiefly concerned in international erce. The increase in Germany's naval establishment was bly the most steady and uniform, for the plan laid down in was strictly adhered to and no surprises were sprung upon ther sea powers. No essential alteration was made in the ard of strength which, up till 1917, was aimed at, viz.: a of two double squadrons and 20 first-class cruisers (58 capi- ips). It was also Germany's policy to refrain from such vements in the ship types as would initiate a process of ing. On the contrary, England was invariably allowed dence in this respect, although Germany was obliged to guard st any inferiority in her material, especially after 1905 the new type of super-battleship was ushered in by the ng of the “ Dreadnought.” This event had the effect of rating the fixed rate of German construction (in 1900 we ight ships; in 1910, 37, representing an increase of some 30 in 10 years), from three capital ships a year at the outset to per year between 1908 and 1911, in order that, after the of the new building phase, Germany should not lag too far d. That England, annoyed by her mistake, should vent her mour on Germany is only another example of the common ncy to make others responsible. To reach the standard set 917 (58 capital ships against England's 94 in 1910) it was sary to lay down three ships yearly, the statutory life of a being fixed at 20 years.

e scheme by which the German Fleet was to be brought up e required standard by 1917, providing for the gradual elim- on of obsolete units, was known to all the world. On economic ds alone, and also because the lines of construction had the first been on a small scale, all over-haste was avoided. atest addition to the navy law in 1912 provided for an addi- of not more than three ships to the nominal strength. Its aim was to place the navy in a better state of readiness, an which the threatening political situation of 1911 appeared to y. It is not to be denied that it was disagreeable to Eng- s supremacy to watch the growth across the North Sea of a naval power, whose strength she by no means underesti- d. Whether the suppression of this navy has repaid Eng- for her active participation in the World War, when she he alternative of *not* placing the mighty power of her own at the disposal of Germany's enemies on land, thereby in obability preserving peace, must remain an open question. as Germany has fallen, she can still look back with pride on ct that the glorious British Fleet did not beat the German open fight at sea.

e very regrettable enmity which exists between two racially nations who, during centuries of history, have been found y side, but never as embittered enemies, will, it is hoped, e softened when an unprejudiced appreciation of the cir- tances governing Germany's struggle for sea power has been shown; when time and a recognition of the common interest of these “ two white nations ”[1] have done their work.

(C. Ho.)

V. DEFENCE

The constitution of the armed forces of Germany has not been determined by the nation itself; on the contrary, its size, organisation and armament are fixed by the provisions of the Versailles Treaty.[2]

Army.—The enlistment must be voluntary, not on the basis of compulsory service. The recruit must bind himself to serve for 12 years or—if he wishes to become an officer—for 25 years. The strength of the army allowed is as follows: 3,797 officers, 20,297 N.C.O.'s, 74,499 privates, 1,407 administrative officers; in addition there are 300 medical and 200 veterinary staff. Of these (including N.C.O.'s) 51,506 are infantry, 15,767 cavalry, 10,644 artillery, 2,838 pioneers, 2,079 signalling troops, 5,572 communication troops and 2,800 medical service. The army is divided into seven Infantry and three Cav. Div., which are formed into two group commands.

Territorial Divisions.—Germany is divided into military regions, in each of which one infantry division is stationed. The seven regions are as follows:—

Region I. embraces the countries east of the Vistula (headquarters: Königsberg).

Region II. includes Pomerania, Mecklenburg, Schleswig-Holstein (headquarters: Stettin).

Region III. includes Brandenburg and Silesia (headquarters: Berlin).

Region IV. includes the country and the province of Saxony (headquarters: Dresden).

Region V. includes Thuringia, Hesse-Nassau, Hesse, Württemberg, Baden (headquarters: Stuttgart).

Region VI. includes Hanover and Westphalia (headquarters: Münster).

Region VII. includes Bavaria (headquarters: Munich).

The cavalry regiments are distributed over the whole Reich. The headquarters of the I. Cav. Div. is at Frankfurt-on-Oder, that of the II. Cav. Div. at Breslau, and that of the III. at Weimar.

Each divisional staff includes an infantry commander and an artillery commander. The pioneer battalions are under the infantry commander and the transport under the artillery commander.

Army Units.—There are 63 battalions with 189 infantry companies, 63 machine-gun companies and 21 trench mortar companies; 79 squadrons, of which 72 belong to cavalry divisions and 7 to infantry divisions; 72 batteries, of which 9 go to form the horse artillery brigades of the cavalry divisions; 14 pioneer companies; 14 signalling companies; 28 horse transport squadrons; 21 motor transport companies, and 7 divisional medical detachments. The infantry is armed with the 1898 rifle. It also carries 1,134 light and 756 heavy machine-guns, and 126 light and 42 medium trench mortars. The artillery is armed with 204 field-guns (7·7 cm.) and 84 light field howitzers (10·5 cm.). In addition, the fortress of Königsberg in East Prussia has 22 pieces of heavier calibre. Heavy artillery, tanks and aircraft are non-existent.

Administration.—The Minister of Defence is the highest authority for command and administration. At its head is a political minister, who is assisted in matters of military technique by the *Chef der Heeresleitung*, who, according to the Defence law, is a general and the superior of all soldiers. For training officer candidates there are one infantry, one cavalry, one artillery and one pioneer school. Enlistment is managed by the smallest units (company, squadron, battery). The proviso that soldiers may not leave the army until after 12 years' service is a great obstacle to maintaining the full strength. The Versailles Treaty directs that only 5% shall receive their discharge before the appointed time in any one year, and in practice this percentage hardly covers the discharges for sickness, incompetence and undesirability. An appeal for premature discharge can therefore only be granted in the rarest cases. This naturally deters many young men from joining, as they are alarmed at the idea of being forced to remain 12 years in the army whether promoted to the higher ranks or not.

---

[1] “ The two white nations ” was the toast whispered in the ear of the captain of the “ Breslau ” by the English admiral when dining on board his vessel, together with other commanders of all nationalities, off the coast of Albania in June 1913. (See Preface, *Kiel and Jutland*, Commander Georg von Hase, London,—*Author's note.*

[2] Part V. *Military, Naval and Air Clauses Articles 159–211.*

Recruiting and Training.—Recruiting is, in fact, influenced by the economic conditions of the moment; under present conditions (1926) recruiting is adequate. Recruits first spend six months at the depôts, one of which is provided for each regiment. Only after this half-year's training are they admitted to their companies, etc. Cadets receive at least four years' training before becoming lieutenants; of these, two years at least are spent with the troops and at least two in schools for the different arms. Anyone who has passed the prescribed cadet examination can become an officer. Soldiers who hold a school-leaving certificate can enter for this examination at the end of $1\frac{1}{4}$ years, others at the end of $3\frac{1}{4}$ years; that is to say, after they have acquired the necessary knowledge for passing a preliminary examination. Every cadet is promoted to officer's rank, irrespective of his origin and purely on the merits of his service, knowledge and his abilities.

The men are trained during their period of service for the calling which they intend to follow on discharge. They are assured of a post in the public service at the conclusion of their 12 years unless they prefer an independent career. In every unit some of the soldiers are elected by their comrades as proxies for economic affairs. A soldier takes no part in politics, but is allowed to join economic and non-political societies. The Defence law provides power, however, to forbid his association with such societies should they be subversive of military discipline and order in the army. For the protection of army interests there is an Army Chamber, which is elected by direct voting and is summoned from time to time by the Minister for Defence. Members of the army are under civil law, and only in case of war may courts-martial be appointed.

In view of the historical development of Germany and her army the Defence law takes specially into consideration the interests of the several states, and too rigorous an application of the centralising principle is not allowed to disturb the territorial constitution of the regiment. Regiments are required to draw their recruits from the inhabitants in the neighbourhood of their stations. Bavaria is allowed a special influence in respect of appointments to commands in the VII. Infantry Div., which is stationed entirely in Bavaria. The supreme authority is, however, vested only in the President of the Reich, who nominates, removes, promotes and releases both officers and administrative officials of the army.

On leaving the army the men receive—according to the Defence Forces Pensions law of Aug. 4 1921—a gratuity on which to live until they find other employment and, further, a civil service certificate which entitles them to apply for an official post in the imperial, state or municipal services. In addition, they receive outfit expenses and, on request, government security to assist them in settling on the land. Officers receive retired pay, which may also be commuted as a lump sum.

The Defence Problem.—The Versailles Treaty declares the aim of the German Army to be the preservation of order in the interior and the "control of the frontiers." In the first of these tasks the German Army has until now been successful; the attacks made by the Right and Left Radical parties on the Government at the time of the financial and economic crash of 1923 were defeated and greater disturbances nipped in the bud. The second task is not easy to carry out with the German Army of 100,000 men. Germany's frontiers are 5,000 km. long, exclusive of coastline; one province is cut off by the so-called Polish Corridor; on the west, the country on the bank left of the Rhine and a stretch of 50 km. east of that river may not be entered by German troops—and it is in this unprotected zone that the West German industrial district lies. Beyond Germany's frontiers lie, on the west, the French Army, with a war strength of some 5,000,000 and the allied Belgian Army, with a war strength of about 800,000; on the east the ring is closed by the Czech Army (war strength, 1,000,000) and the Polish Army, with a war strength of 2,000,000 men. All these armies are provided with excellent modern equipment, and are uniformly trained on the French model. The German frontiers are exposed, and have no protection from natural barriers. In the west, fortresses no longer exist, those in the east are out-of-date and without arma
The eastern frontier is only 170 km. from Berlin. The G
Army has no possibilities of expansion, since all preparatio
mobilisation are forbidden by the terms of the Versailles T
Germany's military inferiority must therefore become g
after the outbreak of hostilities, for the losses could not be
good as fast as they occurred, owing to the absence of any
organisation, and could in the case of a prolonged war h
be made good at all; for the German Empire would sp
become the theatre of war and any possible sources from
reserves might be drawn would accordingly be blocked.

Navy.—By the terms of the Versailles Treaty, the Ge
Fleet was allowed to retain 6 battleships not exceeding
tons, 6 light cruisers not exceeding 6,000 tons, 12 destroye
exceeding 800 tons and 12 torpedo-boats not exceeding 200
Battleships may be replaced 20 years after being lau
destroyers and torpedo-boats after 15 years. The mate
now very much out of date; the battleships were launch
1902–6 and the cruisers in 1899–1903. One light cruis
replacement was laid down in 1920 and finished in 1925. In
the first replacement destroyer was authorised, and in 192
second replacement cruiser and 5 replacement destroyers.
total personnel of the navy numbers 15,000 men. The co
of the navy is vested in the Ministry of Defence (Reichs
ministerium). Under it are placed (1) The Fleet Comma
Wilhelmshaven, with the "Braunschweig" as fleet flag
the commander of the fleet also commands the battleship
sion, and has under him both the commander of the Nort
naval forces at Wilhelmshaven (battleships: "Braunschw
"Hannover"; cruisers: "Amazone," "Emden" and the
torpedo-boat flotilla) and the commander of the Baltic
forces at Kiel (battleships: "Elsass," "Hessen"; cruis
"Nymphe"; surveying-ship "Panther"; 1st torpedo
flotilla and 1st mine-sweeper half-flotilla); (2) the naval sta
in the Baltic and the North Sea; (3) the inspection of traini

VI. NATIONAL FINANCE

Financial Situation before the War.—The central problem
German Finance since 1871 had always been the difficult

ting the limits of the respective powers of taxation of the
and the states (the "Länder" of the Constitution of Aug.
9). The financial policy of Bismarck had solved that
m, not formally but in actual practice, by allotting to the
l Govt. the customs and excise duties, and to the states
wer of direct taxation, which were also the main sources
me of local and municipal government. The income of
rman Empire from indirect taxation was never adequate;
re Bismarck made the Reich "a boarder of the states."
tter had to make good the deficiency by contributions
kularbeiträge). Before the World War, this system failed
n 1913, when the requirements of pre-War armaments
itated a larger revenue for the Reich, and the great defence
oution (*Reichswehrbeitrag*) of that year for the first time
he Reich unprecedented powers in the field of direct taxa-
One milliard of gold marks was raised by a non-recurring
n all property.

rt from this distinction of federal and state income by the
of their respective sources, there was a further significant
stance in the pre-War financial situation. While the
administered the postal service except in a few states, the
ys belonged to the states; thus Prussia had a revenue of
20,000,000 to 240,000,000 marks annually from the rail-
amounting to from one-third to one-quarter of the total
e of the state from taxation and state-owned property.
venue of the Reich derived about 70,000,000 marks annu-
om the postal service, and every year a large amount of
t revenue of the state undertakings was reinvested. With
to the railways, the real actual annual excess of revenue
xpenditure for the whole of the German systems immedi-
before the War was estimated at not far below a milliard
.

total revenue of the Reich, the states and the municipal
ations from taxation amounted to about 4½ milliards of
in 1913. The total public expenditure was considerably
, since the states and municipalities also drew considerable
e from state and municipal land property, from water, gas,
city, etc., works. Of the revenue from taxation about
fths went to the Imperial Govt., which, in 1913, failed to
e the budget, and had to carry over a deficit of more than
illions. This deficit would have been covered in normal
either by the states or probably by a loan. The total
t of the indebtedness of the Government of the Reich at
ginning of the War was about 4,900,000,000 marks. Thus,
eich entered the War with a financial system which com-
unfavourably with the high degree of economic develop-
of the country at large.

War Period.—No wonder that the strain of War expendi-
roke down the whole system. The optimism, common to
e belligerents, based on the idea that "the others would
" stimulated the policy of war loans and therefore of some
ion. The latter, tripling the amount of pre-War mark
supply, did not exceed the similar procedure in most of the
erent nations. By the end of the War, the debt of the Reich
een swollen by 150 milliards of new debts, of which about
alf had been funded; the other half was floating debt in the
of Treasury bills, which after the peace, could only be met
due by printing new mark notes. The revolutionary period
19-20 favoured inflation, and the facts indeed made it
imes even a necessity, the purchasing power of the mark
one of the expedients for the restoration and maintenance
blic order under enormously difficult conditions. The
ements of demobilisation, the occupation payments and
merous kinds of tribute demanded by the Allies added to
ancial difficulties of the Reich.

Erzberger Reforms.—Nevertheless, the whole system of
e was in 1919–20 remodelled by Minister Erzberger, whose
remains the basis of the present financial system. While
ederal constitution of 1919 weakened the power of the
dual "Länder" and strengthened the Federal Govt., the
financial reform of 1920 fundamentally changed the finan-
ystem of Germany, applying the new constitutional principle of unitarism in the field of taxation. Practically the Länder (Territories) became now the "boarders" of the Reich, the exact opposite of the pre-War position.

The first intention of the German republican government was to increase income and property taxes as much as possible. But after a short interval in 1920 inflation was renewed, as heavy reparation payments due under the London ultimatum spoiled any chance of balancing the budget. The bases of the German budget, in addition to the customs duties, which immediately after the War gave very low results, were: the income tax, and, especially, the taxation of wages and the turnover tax. The turnover tax began at the rate of ½%, and was raised steadily until it reached 2½% on any sale made in Germany, and in the occupied territories in 1923 even 3½%. This tax proved to be an enormous burden on consumption, since any commodity on the average changes hands four times in Germany before reaching the consumer. But under a policy of inflation any such burden, heavy at the moment when it fell due, became light at the time of payment, because in the meantime inflation had depressed the purchasing power of money and especially of delayed taxes.

For a time certain taxes based upon the difference of the purchasing power which was high in Germany and lower abroad gave considerable revenues; *e.g.*, the coal tax, which was reckoned at 40% on the price of coal, and from 1920 onwards the newly created export tax which yielded in the most difficult times nearly one-sixth of all state revenues. Both were obviously only transitory in character, the difference between the interior purchasing power of a currency and its value in foreign markets being large during that slow development of a depreciation of currency; if the depreciation becomes rapid, internal prices tend to rise to a gold basis and the gap disappears. The difficulties of German finance were aggravated in the most unhappy manner by the first attempts to finance reparation payments (*see* the other sections of this article on CURRENCY and on ECONOMIC HISTORY). But far more important than the purely financial process of stabilisation was the energy of the Finance Minister, Dr. Luther, who stabilised the budget by strict refusal to pay anything else in other way than by raising taxes. The "miracle of the Rentenmark" is more due to this obstinate determination than to any technical means of stabilisation. Thus Germany entered on her new period of financial and economic life with a very severe taxation.

The mark was stabilised in Nov.–Dec. 1923, and in the beginning of Dec. 1923 the Finance Minister issued two tax decrees, introducing the gold basis for all tax payments and reorganising the whole system of direct taxation. The sales tax was placed on a 2½% basis; income tax was to be paid by all business people on the basis of their turnover, and the tax-free minimum for wage-earners was fixed at 50 marks (£2 10s.) per month. The customs and liquor taxes were completed by a property tax and about a dozen taxes of minor importance. The bulk of the income of the Reich for 1924–5, *e.g.*, about 70% of all, was covered by wages taxes, turnover taxes, customs and indirect taxation of articles of mass consumption. It was a very crude system of taxation which was thus established, though the coal tax necessarily had disappeared with the vanishing difference between interior and world market prices. But it served its purpose. Revenue and expenditure were balanced, and in 1924–5 an unexpected excess of revenue over expenditure became visible. When the Dawes Plan was finally adopted (Sept. 1924) the financial situation of Germany was reasonably sound. The plan brought about two important changes. The railways, which had been forced by the Minister of Finance in 1924 to balance their accounts, were handed over to the Reich's railway company and burdened with a yearly payment for interest and sinking fund of about 660 millions of gold marks for reparations. The customs duties and most of the indirect taxes were to serve as a guarantee for the regular fulfilment of its obligations by the Reich.

Readjustment of 1924.—From Nov. 1924 a period of tax reductions began. Especially the limit of exemption from income tax was raised, and the sales tax rate was lowered, in addition to minor tax reductions. In spite of the reductions, the financial year 1924–5 closed with a large surplus of about two milliards of gold marks (£100,000,000). In July 1925, accordingly, the whole system of taxation was again revised. Income tax rates were lowered, and are now on a progressive scale ranging from 10 to 40%. The tax-free minimum of wage-earners was raised first to 80 marks per month in addition to certain family allowances, then, from Jan. 1926 to 100 marks (£5). The sales tax rate was lowered to 1 % on Oct. 1, and in March 1926 to 0·75 %. The so-called luxury tax almost disappeared. At the same time consumption taxes on tobacco and beer were raised.

Simultaneously the financial relationship between the Reich and the Länder (Territories) was ordered anew. The Territories receive a fixed amount of the revenue from the income tax and the sales tax, at least 2,300 millions. The most important taxes levied by themselves are the land and rent taxes; this latter tax is practically the only important remainder of a far-reaching price control system established during the War. Rents are fixed by the state Governments; about 50 % of the rent goes to the owner of the house, while the states raise the remainder as rental tax; the total receipts are shared between the local authorities for these expenses under this head and the provision of capital for the building of new houses, which is still largely carried out with the help of subsidies financed by the rental tax.

The system of taxation of the Reich draws its most important resources from the income tax (2,200,000,000 marks), the sales tax (1,300,000,000 marks), the customs duties and consumption taxes (1,700,000,000 marks), amounting to about four-fifths of the total tax revenue of the Reich and to about one-half of the total of taxes paid by the German nation.

It is much more difficult to give accurate data with regard to expenditure. The most important change is the reduction of expenditure for the army and navy, which is, however, more than balanced by war pensions and the payments under the peace treaty amounting at present to about 600,000,000 marks annually, but ascending to 1,650 millions in the year 1926–7. The payments to be effected in the "normal year" of the Dawes Plan (*e.g.*, 1928–9) should be covered in the following way:—

	Gold marks
Railways debentures interest and sinking fund	660,000,000
Interest and sinking fund of debentures of industrial and commercial enterprises given to the reparation commission	300,000,000
Budget	1,540,000,000
Total	2,500,000,000

The total expenditure of the Reich, the Territories and the local authorities for 1926–7 is summed up in the following approximate figures:—

	Gold marks
Expenditure of the Reich	4,000,000,000
Reparation payments	1,000,000,000
Expenditure of the Territories:—	
(a) derived from the Reich	2,250,000,000
(b) raised by themselves	1,000,000,000
	8,250,000,000
Local authorities	3,000,000,000
Total	11,250,000,000

In the normal year of the Dawes Plan, *e.g.*, after Oct. 1928, this burden will be about 1,500,000,000 marks higher. Very probably additional expenditure will be incurred on account of unemployment. (J. H.*)

VII. ECONOMIC HISTORY

The dominating note of Germany's economic development before the War was the growth of industrialism. Her population had increased rapidly. It had grown since the foundation of the Empire from 41 millions to 67·8 millions in 1914. The density per sq. m. had increased from 196.6 to 333.1. Emigration had fallen from about 142,000 in 1880–5 to scarcely 26,000 in 1913; Germany had even become a country of immigrants. Apart from the seasonal labourers who went there regularly mostly from Russia and Austria, returning at Christmas, there was a foreign resident population in 1910 of almost 1·3 millions. In 1882 42·5 % of the people had been engaged in agriculture; this percentage had fallen to 27·1 in 1907. The growth of industrialism was accompanied by urbanisation. In 1910 over one third of the German people lived in cities above 20,000, nearly a quarter in cities over 100,000, and the drift to the towns was renewed after the War.

Industrialisation.—Industrialisation had become possible by the growing economic expansion of the world, in which Germany participated through her foreign trade. Her own but recently acquired colonies did not count for much in the actual gr
Though developing at great speed they were rather a reser
the future than a present source of wealth. Notwithsta
tariffs, the growing development of North and South Am
of the African countries and of the Far East, brought abo
the great efflux of men, the export of capital and the applic
of the methods of capitalistic organisation to backward
tries, enlarged the markets of the world.

Germany's import trade, which had averaged 19 million
1880–5, had risen to 72½ million tons in 1908–13, whils
exports had grown from 20·8 to 64·9 million tons. Her pr
was mainly due to the application of scientific discover
industrial purposes, to a very carefully planned out syst
industrial and commercial organisation and to the intelli
and adaptability of the German working men. Her comm
policy favouring trusts and combines in industry facili
exports at the cost of the home consumers who, having t
under a system of agricultural protection as well, would
fared badly if the general development of the world ha
lowered the cost of living all round in comparison with days
by, though after the beginning of the new century an up
tendency in the movement of prices was visible.

The Post-War Crisis

Treaty of Versailles.—The Treaty of Versailles caused
reaching disintegration of Germany's economic life. She
10 % of her population, but over 13 % of her territory in Eu
Large agricultural areas were cut off in the east; in the
important industries like the iron industry were deprived of
raw material. The 1913 home supply of iron ore had amou
to 35 million tons; it had fallen to 5·1 million tons in 1923,
for the great importance of scrap iron in after-War days,
many would have been almost totally dependent on ore im
from abroad. A large part of the metallurgical industry dom
in Lorraine and Upper Silesia was lost (26·7 % of the blast fur
and 15·8 % of the rolling mills), also the important textile i
try (5,866 works) mostly in Upper Alsace were lost. Ge
owners were forcibly expropriated in the ceded territories;
had to be compensated by the German Government. The
principle of confiscation of private property was applied to
man-owned bonds and shares and to German-owned ships,
total proceeds of these confiscations to the Allies have
valued at 6 milliards gold marks, whilst the actual loss
Germany have been figured at about 30 milliards. The
established relations between the producers of raw materia
the manufacturers of finished goods were cut asunder, espe
in Lorraine and in Upper Silesia. The German industri
whose property had been confiscated were bound to use
money they received as compensation in rebuilding new
in Germany. They owned the coal needed for running
whilst their French competitors had to rely on reparation
delivered to them under the Treaty of Versailles from the
of the same rivals, whose works they had bought cheaply.
productive capacity of the iron and the steel industry o
European continent was thus artificially expanded at a
when markets were contracting. The exchange of iron and
ceased to be a natural process, and became part of interna
high politics.

The Allied Powers at Versailles assumed that Germany
quickly rebuild her economic life, as little physical destru
had taken place within her boundaries. To even up their
chances, Germany was to be handicapped. She was bou

he had to hand over a considerable part of her implements duction (ships, mines, cables, etc.) and most of her foreign ments, her future capacity to make payments abroad was d by the excess of exports over her imports as shown by lance of trade. Not knowing her total liabilities Germany o inducement to pay the first instalment as quickly as le; her capacity to do so would have resulted in an increased n two years later, when the definite settlement had to lace.

cts of the War.—German economics were permanently nced by the War. The cutting off of supplies, the loss of ts, the scarcity of labour due to the demands of the army, he wear and tear to which the industrial plant had been ted had forced a system of control on Germany which ore severe than that existing in other belligerent countries. and many raw materials was rationed, and the production ny industrial commodities was supervised by centralised rities. In a country traditionally run by a bureaucratic chy who considered themselves the born rulers of men, s eager for new activities, and where democracy was y represented by socialists, imbued with the idea of state ention in business affairs, that situation was bound to ce lasting effects. Though generally speaking the control nomics during the War was not oversuccessful the idea of socialism appeared to be greatly strengthened.

e collapse of the old régime seemed to clear the way for its t. But the internecine struggle between the small bolshelement, who wanted to follow the Russian example and ass of the organised working men who wanted to bring socialism in a peaceful orderly way, occupied the revolury Government which ruled Germany from Nov. 1918 to 1919. They succeeded in defeating Bolshevism and in g Germany (and with it Western Europe) from its ravages. were very eager for "nationalisation," at least for the isation of monopolistic industries. Two commissions were nted to inquire into this problem, especially into the nationion of mines. They issued some very interesting reports ould not agree upon a practical policy.

e Coalition Govt. which came into power early in 1919 ot very keen on nationalisation. They realised that it was enough to take over a smoothly running concern and man- by Government officials; but it was extremely difficult to anise a broken-down plant. The more energetic part of orking class demanded nationalisation without compensathey wanted syndicalised industries rather than Govern--run concerns. In these circumstances very little was done. the object of paying-lip service to the principle of nationaln and to the council schemes lately imported from Russia, nal councils for coal mining and potash mining were set up, e masters and men, producers and consumers, were allowed , to talk and to vote, without being in a position to wrench ol from the owners. The Weimar Constitution provides he creation of a Central Economic Council (Reichswirttsrat), provincial economic councils and works councils for idual concerns. These latter were to send two of their bers into the board of the company so as to give the workers al control of the business—a provision the only effect of h has been to deprive most boards of directors of their er influence, which was concentrated in the hands of some emely uncommunicative executive officers working hand in with a few big shareholders.

me kind of socialistic tradition survived however. Food s were controlled for quite a considerable time. Rents even are still being fixed; in the days of inflation they amounted ext to nothing when calculated in gold. The entire houseng class was despoiled. Wages were lowered *pro tanto*, as did not enter into them, and the cost of production was ced. In many cases foreign consumers of German exports thus given the rent taken from the German house-owner.

e failure of socialism to bring about the nationalisation of opolistic concerns and its success in despoiling the middle and in irritating the farmers redounded to the advantage of industrial capitalism. Socialists had not dared to take over the broken down industries; industrial owners were quite willing to reconstruct them. They had to make concessions to the working class. They had accepted the eight-hour working day, collective bargaining, greatly improved wages for unskilled labour, the temporary abolition of piece work and the works councils. They did not mind this as long as they could keep the control of prices to themselves. Treaty clauses for delivering coal had put the execution of important peace terms into their hands; they had acquired a place on the international stage. With the continuation of inflation they seemed to wax rich, whilst the state got weaker and poorer. They embarked on a policy of industrial aggregation; whilst formerly there had been a tendency to horizontal trusts, they now aimed at vertical combines to create self-sufficing enterprises, where raw materials, semi-manufactured and manufactured goods were in the same hand.

As time went on economic power became separated from political power. A Coalition Govt. of Socialists, Democrats and Centrists ruled the state. They were held responsible for the humiliations inflicted on Germany, whilst the real power, the economic power, was in the hands of the industrialists and the slowly recovering landed interest, impeded but little by organised labour. As inflation progressed labour became less and less powerful, and when the infuriated middle class turned away from the coalition parties, the weight of political power was turned into the same direction into which economic power had gone before. The state was broken; big business seemed to rule.

Depreciation of the Mark.—From the summer of 1919 to the end of 1923 German economic life was mainly dominated by the depreciation of the mark. The dollar had risen from par (4·2 marks), to about 14 marks after the signing of the Peace in the summer of 1919. It went up continuously until it bought 100 marks by the end of Feb. 1920. After that it fell to 40 in May. Owing to the loan contracted at Spa it remained between 50–70 until early in 1921. The beginning of the Reparations payment under the London plan (May 1921) forced the mark down to 80 by the end of July. It stood at 100 late in September. Its downward movement was greatly accelerated in Oct. of that year, when the news of the partial loss of Upper Silesia became known. Before the Genoa conference the mark hovered round 300 to the dollar, to go down considerably after its failure, its downward course gathering speed after the murder of Rathenau (June 24 1922). The demand for a moratorium and the abortive conferences about it brought it down to 4,000 in Oct. and 8,000 in Nov., where it remained through the rest of the autumn of 1922. On the day after the occupation of the Ruhr (Jan. 11 1923), it quickly fell to 30,000, reaching 49,000 on Jan. 31. At that time the Reichsbank intervened, bringing down the dollar to 20,000 and keeping it there until April 18. But the dislocation of economic life and the great strain on the finances caused by the struggle of the Ruhr forced the Government to use the printing press at a formerly unheard of rate. The stabilised mark collapsed. By the end of Aug. the dollar had risen to 10·3 millions. And when currency reform was under way, just before the issue of the new Rentenmark, the price of the dollar was practically settled at 2·5 billion marks. No depreciation on such a scale had ever been known, save in Russia.

The primary cause of the decline of the mark was faulty Government finance. At the end of the War the funded debt was estimated at 103 milliards gold marks. Current expenditure had been met by treasury bills, which the Reichsbank was allowed to discount and to use as cover for its notes. From time to time the outstanding Treasury Bills were converted into a funded loan, nine different issues of which were placed amongst the public, bringing in a total of 98·5 milliards.

The War was followed by a revolution. Demobilisation had to be carried out under very difficult conditions. The revenue went down almost to nothing. So most of the expenditure had to be met by Treasury Bills. The Reichsbank became the chief support of the Government, issuing notes against such Treasury Bills as were not taken up by the public. Retrenchment was impossible. When armed insurrection is threatening the foundations of the State, extravagance may be wise and saving may be foolish.

As soon as the worst danger was over, financial reform was undertaken. But the chances for its success were small. The organised working class who were the main support of the Government and on whose co-operation the maintenance of order depended were rather disillusioned. There was a great deal of privation all over Germany. The millennium which they had dreamed of had not come. They had not succeeded in wrenching the control of capital from the capitalistic classes. The least they could do to meet their supporters was to claim for them an enlarged share of the nation's income by way of increased wages. The revolution, it has been said, degenerated into a struggle for higher wages, short working hours, and overemployment in works and Government departments, so as to avoid dismissals. This meant increased Government expenditure, which could not be met by taxation of the working class. In a country where prices are rising rapidly and where there is an actual scarcity of commodities indirect taxation cannot be resorted to by a Government mainly dependent on the masses, the support of which is by no means certain. Taxation was bound to fall on the propertied classes.

As long as the socialistic movement was in the ascendant—even at the election of 1919 socialists failed to get a majority—the capitalist classes, including the landed interest kept quiet. They did not openly fight against taxation. But they naturally tried to save as much as they could. Notwithstanding all sorts of severe regulations a great deal of movable property left Germany in the revolutionary days 1918–9. The so-called " flight of capital " started—a movement quite legitimate in early days, when violent confiscation seemed imminent. Later on it developed into an effort to save property from the severe taxation involved in the financial reform proposed by Erzberger.

The Erzberger Reforms.—In Feb. 1919 a Coalition Govt. had been formed by the Majority Socialists, the Centre party and the Democrats. Differences of opinion about signing the treaty of Versailles led to the withdrawal of the Democratic party. The Majority Socialists and the Centre, who counted 253 in a house of 423 formed a new Government. And Erzberger, who up to now had been Minister without portfolio became Chancellor of the Exchequer. Being dependent on the Socialist vote and having been all his life the representative of a small, rather anti-capitalistic group in the Centre party, his scheme of taxation was bound to weigh heavily on the propertied classes. He introduced a capital levy originally devised to wipe out the deadweight debt and a thorough going taxation of War profits, which nearly wiped them out. He clearly saw that the Treaty of Versailles, which put a crushing burden on the Reich, necessitated the creation of a central Exchequer to which the individual States must be made subservient. All through German history the states have jealously guarded their rights of financial sovereignty. Even Prince Bismarck in the hey-day of his power had not been strong enough to make the central Treasury independent of their control. Erzberger made the Reich the dominant partner in finance. He deprived the states of the main sources of taxation, such as the income tax. He organised an imperial service for their collection and their administration, superseding the old state services. He amalgamated the railways, which hitherto had been the property of the individual states, into the imperial railways. Under the shadow of the Treaty of Versailles he succeeded where Prince Bismarck had failed.

Though part of this legislation was watered down while passing through parliament, it would have weighed heavily on the propertied classes, if the taxes had been paid immediately in stable money, with no interval for the further depreciation of money. But this was plainly impossible, as the new imperial inland revenue service could not start immediately. If properties were valued in marks at a time when the value of the mark was fairly high, and if taxes assessed on this value were paid at a later time when values were low, the burden of taxation could be easily shifted. At the same time the burden of the government debt would decrease automatically.

Reparations.—As the Treaty of Peace had not fixed Ger
total obligations before May 1921, the Budget did no
tain proper estimates for reparation payments. This w
merely a grave technical hindrance to reform, it put a pre
on financial procrastination. For it was clear that a c
whose finances were sound and solid would be charged
heavier indemnity than a country on the verge of bankr
Balancing a budget after a long spell of inflation is always
cult and very unpopular undertaking. If by balancing it
the total obligations are likely to be increased in the inte
hostile foreign creditors, the impetus to reform will be
weakened. And the same holds good of the taxpaying m
the individual taxpayer. What good is it, he was bound to
himself, to strain every nerve so as to enable the exchequ
square all its liabilities, if by doing so I am merely throwin
new indefinite liabilities?

The London Ultimatum (May 6 1921) enormously stre
ened this attitude. The total demands on Germany amoun
132 milliards of gold marks; the yearly payments might easil
to eight milliards, or twice the German exports and about d
the total revenue of the Empire before the War. The outlo
financial reform became hopeless. Inflation proceeded, an
business world began to realise that the public's loss mig
their private gain. They began to look upon the further d
ciation of the mark as upon a fateful destiny and, being una
able, as quite a legitimate means for getting rid of their de

The Budget.—Some courageous efforts to balance the b
were made nevertheless. A plan of either valorising the ta
revaluing the amount of taxes payable on the day on which
fell due was discussed in 1921. But as it was unwisely
" taxation of real values " and imbued with a certain am
of socialistic acerbity it could not be carried. It was transfo
much later into a forced loan, levied from all property o
but in such a stupid way that the owners could take u
loan in paper marks at a time when it cost next to not
When the loan was passed in July 1922 the owner of a pro
worth 100,000 gold marks, had to subscribe 1%, which a
then rate would have come to about 150,000 paper mark
he did not pay in time he was subject to a fine. But if he di
the fine and settled at the end of the year he had reduce
liability from 1,000 gold marks to 90 gold marks.

So the issue of Treasury Bills against which notes were pri
remained the chief prop of Government finance. As time we
and as the public became more sceptical the proportio
the bills taken up by the Reichsbank and those taken u
the public changed considerably. In Jan. 1921 the bank
50.6 milliards and the public 104·9; in Oct. 1922 the figures
reversed: the bank held 477.2 milliards and the public
Moreover, political events continually upset the balancing o
budget. The equilibrium established at the rate of 300 mar
the dollar, would immediately be upset if, in consequenc
some political action, the mark went down and prices wen

There was no immediate parallel movement between
amount of notes issued and the depreciation of the mark,
there was a very distinct connection between political events
the fall of the exchange. The loss of Upper Silesia, the acts o
Reparation Commission, the murder of Rathenau, the occupa
of the Ruhr, the speeches of Poincaré are the outstanding
at which the mark took a headlong downward flight. Each
political crisis brought about a huge demand for foreign excha
in Germany. As the German business world had to get raw
terials, or the means to pay for raw materials, or the chance
keeping part of their stock intact, they had to buy foreign
change, whilst foreign purchasers of marks got frightened
sold out at any price. Notwithstanding stringent regulations
ital fled from Germany in many forms.

In the autumn of 1922 the situation had become almost h
less. The German Government had been asking for a mora
rium. The Reparation Commission might have been willing
grant it, but the French Government proved recalcitrant.
conference of neutral experts was called to Berlin to consider
possibilities of stabilising the mark. It agreed with a small gr

man economists that the mark could be stabilised provi-
y with the gold of the Reichsbank, and that an effort in
rection might be made the basis for a reasonable repara-
ttlement. Public opinion, however, greatly influenced by
ss interests, considered a previous agreement on repara-
conditional to stabilisation. Nothing could be done; the
ance for bold action was missed.

pation of the Ruhr.—A few months later the Ruhr was
ed. The mark immediately responded by falling to 49,000
to the dollar. A tardy stabilisation effort was made in
hich succeeded for about eight weeks. But the Gov-
nt expenditure for the support of the people in the Ruhr.
works had come to a complete standstill, was enormous,
end of July the total note issue had reached 43·6 billions
t two billions at the end of Jan., the amount of Treasury
utstanding 57·8 billions, whilst private bills discounted
Bank had risen to 18·7 billion marks. Selling bills to the
had become a very profitable business. Debts were con-
d in marks when the dollar was 30,000 and paid back three
s afterwards when it had risen to 1,100,000; even a bank
18% was of no avail. By the end of May the bank's gold
ad fallen from one milliard to 758 millions; on Dec. 1923 it
own to 467 million marks.

he summer of 1923 social disorganisation had become im-
t. The farmers refused to sell goods against depreciating
; the big industrial works revised and paid wages bi-weekly,
ng from a kind of dollar basis. But if the money received
ot spent before the new quotations from New York had
d the shops its purchasing power might be halved. Whilst
untry was drowned in a flood of paper money a scarcity in
notes was frequent, for the printing press could not keep
vith the rise of prices.

a long time wages had been below the level of the world
t, as home prices had been rising more slowly than prices
d. It was expected that this advantage in the cost of pro-
n would enable Germany to produce more cheaply than
countries and to flood the world market. Nothing of the
ook place. For 1922 German export reached 6·2 milliard
narks and for 1923 5·4 milliard gold marks, against 10·2
rd in 1913. Though the accuracy of these figures may well
ubted in some respects, there is no evidence whatsoever to
e a flooding of foreign markets, the total weight of German
ts having dwindled from 74 million tons in 1913 to 22 mil-
ons in 1922. As foreign trade was controlled by all sorts of
fficial syndicates, exports were often restricted with the
of keeping the home customer quiet. And as German ex-
depended on imported raw materials, the scope for expan-
f industrial exports was small indeed, as imports were im-
by the fall of the mark. The fear of further depreciation
ed the German exporters to keep part of their revenues
d rather than return them to Germany. The McKenna
valued German assets outside Germany at about seven mil-
gold marks. Such people as were unable to invest their sav-
a foreign country bought dollar or pound notes; and though
rdinary citizen was forbidden by law to purchase these
they circulated quite freely though, of course, clandestinely,
er Germany.

e Rentenmark.—At midsummer 1923 the mark as medium
culation was doomed. An emergency currency such as
certificates" was suggested. To stave off the crisis, whilst
ncy discussion went on, taxation was put on a gold basis;
e first time for many years the landed interest had to bear
are. The plan of the reformers of Oct. 1922 to stabilise first
o settle the reparation business later on was taken up by its
dam opponents. But the obstacles to reform had grown
nously. The Reichsbank, which had not been willing to risk
ld in 1922 when there was a fair chance of success, had
n away half of its holdings in the hopeless endeavour to
the course of the mark at a time when the printing of
s proceeded at fantastical speed. A foreign loan, to ensure
ss, could not be had; a home loan, it was supposed, was out
e question.

A plan for the issue of a new money, to be guaranteed by mortgage bonds, inscribed on real estate, was broached. These notes—they were later called the Rentenmark—were to be secured by interest-bearing bonds; they could automatically be converted into them. The interest was to be a first charge on real estate. The total issue of the new money was to be limited to 4·2 millards, 2·3 of which were to be lent to the Government; the rest to private concerns. The plan which was to provide the Government with funds to carry on the struggle in the Ruhr would have failed lamentably if the Stresemann Govt. had not had the courage to stop the fight, thus doing away with the main cause for unlimited expenditure. It cut down the total issue to 3·2 milliards, and greatly modified the whole scheme. The Government succeeded, against all expectations, in floating a gold loan, which gave it a breathing space; it was echeloned in such small points that it could be used as stable currency during the period of transition. When Luther became chancellor of the exchequer the new currency, the Rentenmark, was issued, and the work of stabilisation began. It succeeded completely.

The cessation of passive resistance in the Ruhr was followed by the ruthless cutting down of expenditure, especially of salaries in Government offices, at a rate probably never heard of before in a civilised country. This brought about the equilibrium of the budget, the gold loan and the loan from the Rentenmark issue bridging over the temporary gap. The new president of the Reichsbank, Dr. Schacht, restricted the bank's credit facilities, thus cutting off business from their accustomed supply of cheap money. They had to rely on their own savings which they had invested in foreign exchange. These hoards played the part of a foreign loan usually contracted for stabilisation purposes. They constituted the foreign currency fund on which the bank could draw for maintaining the mark exchange. German business needing cash had to sell foreign exchange, against which the bank issued its notes, which thus became gold exchange covered. The flight from the mark, which originally had destroyed the German currency, later on provided Germany with the means of stabilising it. After the first quarter of 1924 the foundations for monetary reform had been safely laid. And on this basis negotiations for a reasonable settlement of the reparation problem were started which ended in the acceptance of the Dawes Plan.

The Dawes Plan.—As her economic life was at a low ebb, Germany could not be made liable for a lump sum anywhere within reach of French expectations. The experts had to fix Germany's obligations in such a way as not to sap her energy by incertitude, and at the same time give the Allies a chance of participation in her growing wealth in case she made a quick recovery. To do this Germany's obligations were, so to speak, divided in two halves; the one was to consist of 11 milliard gold mark bonds secured on the German Govt. railways and of five milliards bonds registered as obligations on German industrial property. At a rate of 5% interest and 1% sinking fund these bonds yielded 960 million marks a year, which were to come from the proceeds of the mortgaged properties. These 960 million constituted the minimum annuity to which Germany was liable. If these bonds could be sold at par their total value would be 16 milliard gold marks; the value of two milliard gold marks preference shares of the German railways might be added. This capital sum of nominally 18 milliard gold marks would be paid off within 37 to 38 years by means of a sinking fund of 1%.

The other half was an annuity not yet capitalised, the proceeds of the railway tax and of customs and excise yielding about 1,250 million gold marks a year. The administration of these revenues has to be supervised. An additional surplus was to be paid, in case Germany's capacity to pay increased, which was to be deducted from a carefully constructed index. If the contrary movement took place and if its transfer abroad affected the exchange unfavourably these revenues were to accumulate up to five milliard marks. When this figure was reached payments from these sources would be stopped, until an improved economic situation could permit the resumption of payments abroad. A transitional régime, including a kind of a diluted moratorium, was to be in force from 1924–7 when the yearly payments were to be 1,000, 1,200, 1,220, 1,750 million gold marks, part of them to be defrayed from loans or from sales of railway shares.

The first result of the Dawes Plan was the flotation of a German loan of 800 million marks in the financial centres of the world, which enabled Germany to pay most of the reparation payments of the first year and to put the Reichsbank on a sound basis. Reorganisation was to furnish amongst other things the mechanism for the gradual disappearance of the Rentenmark.

THE COUNTRY'S RECOVERY

After inflation Germany was an empty shell. The middle class, the owners of mortgages, of state, municipal and industrial bonds were practically ruined; so were the house-owners who had received scarcely any rent. A tardy restoration was enforced by public opinion 1924–5: private debentures, especially mortgages, were to be valorised at 25% of their original value, the payment to be postponed until 1932. The owners of public securities were to receive but scanty compensation, owing to the prior lien of reparation claims. The loss of the creditors has not benefited the debtors. States and municipalities were, no doubt, relieved of their burdens, but the ruin of well-to-do tax-payers was a very heavy burden to them.

Agriculture.—As far as agriculture is concerned, no fundamental changes have taken place. The big estates have not been split up, though under the different closer settlement schemes 7,300 new holdings have been created in Prussia. Big entails (Fideikommiss) have been broken up. But until lately land has not come into the market in great quantities. It is only now, when an agrarian crisis is setting in, that estates, especially big estates, can be had for a song. Whilst inflation lasted agriculturists had a good time. They saved the money due on their mortgages; some of them may have relaxed their efforts and produced less; others raised their standard of living. The wiser ones—and there were many of them—spent largely on permanent improvements. The great progress in the chemical industry, especially the production of artificial nitrates, enabled them to intensify their production. With a good harvest prices were bound to fall. Working capital, especially for big owners, was rather scarce. As the rate of interest had risen considerably, the number of years' purchase to be given for an estate had considerably diminished, and the total assets capable of being mortgaged had shrunk, whilst the total interest remained the same. Moreover, mortgages were very difficult to get. So financing was done by bills of exchange, which fell due after the harvest and forced the owners to sell at low prices. The agricultural crisis imminent in the summer of 1925 was aggravated by an embargo on grain; its abolition brought prices to the level of the world market, a rise which has not been considered sufficient, inasmuch as a good world harvest depressed the general level. New corn duties of three marks per doppelzentner and a refund for exportation were clamoured for and granted; so far they have been a failure as a remedy for the crisis.

Industry.—The bonded debt of industry, from which inflation freed it, has been estimated at about five milliards of gold marks. Apart from that, the bank had granted huge credits to industrialists, which were paid back in valueless money and cost them very little. Many enterprises used these savings for purposes of expansion, thus increasing their productive capacity; though this is by no means true of all enterprises. Many works, not having been subject to competition for a long time, want modernisation badly; entire trades, like the textile trade, have greatly shrunk. The number of spindles in cotton mills fell from 11,186,000 in 1913 to 9,464,000 in 1924; the consumption of cotton from 486,000 tons to 271,000.

Changes all over the world have greatly affected the position of German industry. The production of bituminous coal is suffering from the competition of lignite, of electricity and of oil. The iron industry, quite apart from the structural changes brought about through loss of territory, has lost the armament market as well as the building market; the construction of houses is far below the pre-War output of 200,000 dwellings a year. The great use of scrap iron has diminished for the time the importance of iron ores.

Inflation greatly facilitated the concentration of industri a few hands by all sorts of combines. Shrewd business borrowed money from the banks to buy shares and plants, repaid the loans in valueless paper money. Some of the combines were mere amorphous aggregations which fell to p immediately when credit became dear. Others chose the so-c vertical combination, trying to concentrate in one hand w representing the different stages of production. This wa type which has been closely identified with the name of Sti The home market was secure, as, owing to falling excha foreign goods could not compete. Wages reckoned in gold low, trading conditions profitable.

After the mark was stabilised, it was quite clear that indu as well as agriculture was a loser. The middle class, having ruined, had no purchasing power. Wages, though consider higher than during inflation days, were below the peace l The average weekly wages of a skilled metal worker had 36·36 marks in pre-War days; they were 31·27 marks in 1924. As the cost of living index had risen to 111 (rent incluc wages represented a good deal less purchasing power than be

Foreign Trade.—Exports could not make good the defici purchasing power at home. Germany's total exports fallen to 6·5 milliard gold marks, 1923–5, against 10·2 mill gold marks in 1913, not making allowance for the rise of pr As the purchasing power of neither the home market nor foreign market equalled the productive capacity of incre plants, many works were running at half speed. And as o head cost added an increasing proportion to costs when output was small, prices needs must be comparatively h Given the small purchasing power of the home market prices were bound to lead to reduced sales, and reduced sal their turn must bring about rising costs. Adjustment was slow as for a long time there was no real free competitio Germany. Foreign competition was kept out by tariffs as as by the use of import licenses (a practice which has al disappeared by now). The sheltered home market was trolled by cartels whose policy was to give a chance of livin the most inefficient member-works. All this really mea reversal of the old German business policy, which had insiste a big turn-over and a small profit; the new policy aimed at profits and small turn-overs. As the political power in econo affairs remained in the hands of the highly organised produ of raw materials and half-finished goods who insist on high pri the general price level was driven up. By the end of 1925 cost of living index had reacted, and nominal wages were ab the pre-War level. The average for the metal workers in 1925 was 46·24 gold marks (skilled) and 31·16 gold marks (skilled). In the midst of a crisis Germany had high prices rising wages.

Most of the legal obstacles to exportation had disappeare 1925. Germany was admitted to the most favoured-nat treatment, and the licence system was on the wane. hostile tariffs and decreased international purchasing po have remained, affecting German foreign trade in a pecu way. Whilst English exports have risen from 284 marks head 1913 to 385 marks 1923, Germany's quota has fallen fr 149 gold marks to 139·6 gold marks 1925. German indus clamoured for a tariff, with the double object of fighting hos customs barriers and of enabling her to recoup herself on home market whilst exporting cheaply abroad. The tariff carried by a combination of the landed interest and the p ducers of raw materials and half-finished goods. It came i force on Oct. 1 1925.

Credit Position.—Generally speaking it has not achieved mu It may have facilitated the conclusion of minor commer treaties. But the poverty of the consumer who can either b goods or keep his money in the bank, but who is unable to both as he did in days gone by, has deprived industry of working capital, though the valuation of the plants is rather hi Capital is scarce, and rates of interest (long term) at 12% a more are even now by no means the exception. The Reichsba was bound to restrict credit, as it had to protect the currency a

nted to force down prices. Government increased the ngency by overtaxing the people from fear of failing in their igations under the Dawes scheme. The surplus in the Treasury either gone to States or municipalities which not always d it wisely, or lent it out directly or through the banks in her an indiscriminate way. Foreign credits have been re- ted to on a considerable scale. They have been estimated at milliard marks, which accounts of course for Germany's avourable balance of trade (imports 12·5 milliard gold marks, orts 8·8 milliards gold marks). The lending capacity of the ks is very limited. The total capital of the four big Berlin ks before the War (reserves included) amounted to 1,059 lion marks, their deposits to 2 milliards. At the end of 1925 ital and reserves have shrunk to 546 million marks and osits to 1·76 milliards. The savings bank deposits have en from 18 milliards gold marks to 2·3 milliards.

The result of this scarcity of credit, which is really due to fficiency of income, has been a crisis which is now at its height. Amorphous aggregations like those of the Barmats have long ago gone to pieces, but even vertical combines, like the Stinnes concern, had to be dissolved. And the typically German form of the horizontal combine, the cartel, which is an organisation of works producing the same class of goods with the object of getting a monopoly price high enough to keep the weakest partner going, has broken down. There is a tendency already materialised in the chemical trade, and on the way to materialisation in the steel trade, to form a real trust with its advantages of large scale production. Germany is on the way to recovery. But the transition is slow and painful. Owners are naturally unwilling to write down capital on the necessary scale, as indicated perhaps too pessimistically by the valuation of shares on the stock exchange. Bankruptcy is rampant. In Dec. 1925 commercial failures, which were as low as 30 a month in Jan. 1924, have gone up to 1,660, thus greatly surpassing the monthly average of 815 in 1913. Unemployment is spreading. Whilst during the hey-days of inflation (second half of 1922) less than 50,000 people received unemployment benefit, their number had grown to 1,485,931 at the end of Dec. 1925. Emigration is starting again, notwithstanding all sorts of obstacles; 58,714 emigrants left Germany in 1925. Fortunately, trade unionism has regained its strength. The problem lying ahead of Germany is, how can she become a country with a low level of prices and a comparatively high level of wages.

VIII. CURRENCY.

The New Bank Amendment Act.—On Jan. 1 1911 the provisions of the Bank Amendment Act of June 1 1909 came in force. By this Act the note issue privileges of the Reichsbank were extended for a further 10 years, and the tax-free portion of the issue was again increased (from 450,000,000 marks to 550,000,000 marks; at the end of each quarter to 750,000,000 marks). The note circulation was permitted to exceed the cash reserves by those sums without the Bank having to pay the 5 % note tax. This measure was partly due to the severe economic and financial crisis of 1906–7, which had led to abnormally high official discount rates, and to the institution of a thorough inquiry into the working of the Central Bank and of the whole German banking and credit system. The committee of investigation, of which Dr. Havenstein, the president of the Reichsbank, was chairman, had recommended, firstly, that the gold holdings of the Reichsbank should be increased by a larger issue of small notes, by encouraging payments which did not involve the use of cash, and by corresponding measures in regard to foreign payments; secondly, that measures should be taken to diminish the demands for credit from the Reichsbank on the part of public and private bodies, and to strengthen the security and liquidity of the deposits in the banks. The new Bank Act gave effect to most of these recommendations. Bi-monthly balance sheets of the banks were published in the *Reichsanzeiger* from 1912 to Aug. 1914 and again from the beginning of 1925. The liquidity of the German banking and currency system was improved.

The average annual gold holdings of the Reichsbank rose from 827,600,000 marks in 1911 to 1,067,600,000 marks in 1913, the note circulation of the Bank from 1,663,600,000 marks to 1,958,200,000 marks, the gold cover from 49·7 % to 54·5 %, the holding of bills from 1,077,800,000 to 1,136,000,000 marks, and the total turnover from 377,500,000,000 to 422,300,000,000 marks.

The official discount rate was fairly high during the years immediately preceding the War owing to expanding trade and to the tension on foreign relations, the average rate for 1911 being 4·397 %, for 1912 4·946 % and for 1913 5·885 %. Credit transactions both at home and abroad were regulated by the gold standard, and fluctuations were lessened by the intervention of the Reichsbank. The supply of and demand for capital were harmoniously adjusted, and the markets for short and long term loans were adapted to varying needs by the automatic operation of interest rates. The Reichsbank acted as the bankers' bank and as the ultimate source of credit in country. The whole credit and currency system stood in the clos relation to the economic organisation of Germany and to its devel ment as a great industrial and international trading centre. Thou the balance of trade was adverse, as in other advanced indust countries, the invisible exports were sufficiently large to enabl steadily increasing volume of capital investment abroad.

The War Period.—When the World War broke out the Reichsba was faced with new tasks of unexampled magnitude. It also to over the management of the loan offices (Reichsdarlehnskass which were set up in 1914 to facilitate borrowing against goo stocks, shares, etc. It was able to meet the tremendous demands cash and loans during the mobilisation period and in the early sta of the War without any appreciable rise in its discount rate and wi out the necessity for a general moratorium. It is true that on Aug 1914 its notes were declared irredeemable in gold, and the liabil to pay note tax on excess issues was abolished. Loan office not were recognised as a cover for Reichsbank notes, and Treasury Bi with not more than three months to run were admitted for discou at the Reichsbank, and accepted as cover for the note issue. T disregard of well-established currency principles would probably have had very serious results if, as was at first assumed, the War h been of short duration.

As the Reich acquired control over an ever larger proportion of t economic system for War purposes its demands for credit beca predominant, and the requirements of private industry and co merce, which at first were very great, fell increasingly into the ba ground. The necessary sums were in the first instance made ava able by the Reichsbank in the form of Treasury Bill credits, and th converted almost completely into long-term war loans. By a su cessful collection of gold from the hands of the public, a fund w created for external purposes which proved of the greatest imp tance, both in the War and in the difficult post-War period, as means of payment for vital imports. The Reichsbank discount rat which at the outbreak of the War was raised to 6 %, was reduced the middle of Dec. 1914 to 5 % and kept at that figure till the mid of 1922. But owing to the lack of a free gold market it lost a gre part of its normal influence as a regulator of the economic syste The circulation of Reichsbank notes rose from an average 1,958,000,000 marks in 1913 to 5,409,000,000 in 1915, to 9,010,000,0 marks in 1917 and to 13,682,000,000 marks in 1918.[1] The avera gold holdings of the Reichsbank rose from 1,068,000,000 marks 1913 to 2,387,000,000 marks in 1918. The highest figure reach was 2,550,000,000 marks on Nov. 7 1918 (including gold handed ov by Russia under the Brest-Litovsk Treaty). The average gold cov of the note circulation fell from 54·5 % in 1913 to 17·5 % in 191 The value of the mark remained near to parity during the first tw years of the War, and even at the end of the War had only fallen about half its pre-War value.

Legal Changes.—The most important changes in the legal provisions affecting the Reichsbank after the War were (1) the reductio in the minimum cover for the notes, by the Act of May 9 192 (2) the authorisation of the Reichsbank to undertake forward exchange business, by the Act of Dec. 16 1919; (3) the inclusion of gol stocks held by the Reichsbank in foreign central banks as prima cover for its notes, by the Act of March 4 1922; (4) the so-call autonomy law of May 26 1922, which made the management of th Reichsbank independent of the Government of the Reich and e trusted it solely to the managing board of the Reichsbank, thoug this did not appreciably affect the policy of the Bank.

Inflation.—During the years following the World War the economic life of Germany declined, reaching its nadir in 1923. Al attempts to stabilise the falling currency were unsuccessful in vie of the various burdens imposed on Germany by the Allies. Th value of the gold mark in terms of paper marks, as measured by th exchanges on countries with the gold standard, was 2·08 paper marks in Dec. 1918, 10·8 in Dec. 1919, 17·39 in Dec. 1920, 45·72 i Dec. 1921, 1,750 at the end of 1922 and after Nov. 20 1923 a million million, Since the printing press could not keep pace with the depreciation, emergency money was issued without proper control and utter confusion ensued. The money and capital market came to a complete standstill; interest rates rose to fantastic heights; the accumulation of capital ceased. There was a feverish chase after goods and foreign securities. The finances of the state lost all basis. The last phases of this evolution suddenly became catastrophic; the mark became useless as a medium of payment, for in many cases it was no longer accepted, and had already been largely rejected by the business community as either a measure of value or a basis of calculation.

The Rentenmark.—In the chaos of inflation there appeared the beginnings of the transition to a stable currency in the form of loans with a fixed value based on gold or commodities; mortgages, credit and insurance transactions, savings bank deposits, commercial contracts, etc., being reckoned in terms of gold or some other commodity standard. Finally, the Rentenbank was created by the Order of Oct. 15 1923 and was astonishingly successful in leading the way to the stabilisation of the currency. While the convening of the wes Committee was still under discussion Germany succeeded, in cumstances of the greatest stress, in stabilising her currency un- ed, and in resuming control over her finances. The success of the ntenbank was largely due to the fact that with its help the ances of the Reich were supported until the collection of the enue in terms of the new currency, and energetic measures of nomy had enabled the budget to be balanced. The Reichsbank s able, on account of its credit policy, without legal regulation, to intain the value of the Rentenmark at the equivalence of 1 ntenmark = 1 billion paper marks = 1 gold mark, until the final rency reform was introduced.

---

[1] *Cf.* the figures for the end of each year on pp. 120–1 of *Memorandum on Currency and Central Banks, 1923–4* (Geneva, 1925).

n order to support the value of the currency in the meantime, the rman Gold Discount Bank was created (April 1924) for the pur- e of providing industry and commerce with gold credits, chiefly export purposes. The unity of currency and credit policy was ured by entrusting to the Reichsbank the management of the ld Discount Bank and the granting of Rentenbank credits for iness purposes.

Acts Regulating the Reform.—The adoption of the Dawes Plan led the passing on Aug. 30 1924 of four Acts—the new Bank Act, the nt Act, the Private Issue Bank Act and the Act for the redemption the notes in circulation of the Rentenbank. These Acts came into ce on Oct. 11 1924 after the floating of the German foreign loan of ,000,000 reichsmarks, in accordance with the proposals of the erts. The Rentenbank and the Gold Discount Bank were put o liquidation, but the latter subsequently resumed its activity as a dit institution in the guise of a department of the Reichsbank. e further issue of Rentenbank notes was prohibited, and the ichsbank was required to withdraw Rentenbank notes in circula- n, within a period of 10 years.

By the Mint Act the gold standard was again proclaimed with the chsmark as the currency unit, and with the same gold equivalence the pre-War gold mark, *i.e.*, 1 km. of fine gold = 2,790 reichsmarks. e old gold coins retained their validity and also the silver coins nted under the Act of March 20 1924, the rentenpfennigs and the pper pfennigs issued under the law of July 9 1873. All other coins viously minted of silver, nickel, aluminium, iron and zinc, lost ir validity. The minting of silver coins to the value of 1–5 reichs- rks was authorised by the new Mint law. Apart from the Reichs- nk notes only the gold coins were given unlimited legal tender. ver coins were legal tender up to 20 reichsmarks and smaller en coins up to 5 reichsmarks.

Under the new Bank Act the essential features of the Reichsbank e retained, but important modifications were made in accordance h the principles of the Dawes Plan, one of which was the introduc- n of an element of foreign co-operation exercised through the neral Council and the Commissioner of the Note Issue, who is a eign member of the General Council. The management and ministration of the Reichsbank was placed, as under the old Bank , in the hands of the Managing Board of the Reichsbank which sists exclusively of German nationals. The original capital of the nk was contracted from 180,000,000 marks to 90,000,000 reichs- rks. The new Bank Act provides for a capital of at least ,000,000 reichsmarks.

The functions of the Reichsbank, resulting from its position as the tral bank of issue, were laid down in the same terms as in the old nk Act, but the provisions in regard to credit were made more ngent. The power of the Bank to grant credit to the Reich, the leral States and the municipalities were narrowly limited or bidden altogether. The Reichsbank was also given the new func- n of holding on deposit the sums paid in reparations, for the ount of the agent for reparation payments. The exclusive right of ing notes was granted to the Reichsbank for 50 years. While on one hand the note circulation was subjected to more severe condi- ns with regard to its cover, it was also made more elastic, and greater edom of action was secured by the admission of foreign bills of hange as cover for the notes in addition to gold. The obligation the Reichsbank to redeem its notes in gold was for the time being pended, and its reintroduction was made dependent on the proval of both the Managing Board and the General Council.

Quantity in Circulation.—During 1925 gold coins were not in cir- ation. The following tables show the volume and composition of money in circulation in Germany at the end of 1913 and 1925:—

1913
(In Millions of Marks)

Gold Coins	Token Coins	Treasury Notes	Reichsbank Notes	Private Bank Notes	Total Circulation
2,750	850	100	2,593	160	6,453

1925
(In Millions of Reichsmarks)

Token Coins	Reichsbank Notes	Private Bank Notes	Rentenbank Notes	Total Circulation
582	2,961	190	1,476	5,209

Reichsbank Policy.—The Reichsbank was faced with very great difficulties in carrying out its economic functions after the stabilisation of the currency owing to the inevitable crisis of economic reconstruction, to the reparation payments and to the flood of foreign credits which came into the country following on the Dawes loan. Although the new Bank Act had re-established sound principles of banking policy it was not possible for them to be applied in the same way as before the War. As a result of the disrupting effects of war and inflation upon circulating capital there arose a grave discrepancy between the supply of and demand for capital, which only by degrees became less acute. The mechanism of the money and capital market, which had completely broken down, was at the beginning of 1926 still by no means normal, and the automatic regulation of the markets for short and long term loan capital was not yet restored. Under such abnormal conditions the Reichsbank (from April 1914 onwards) found itself compelled to put into force a drastic rationing of credit in addition to a cautious adjustment of its discount rate. It was not till the end of 1925 that it was able to modify in a tentative way the severity of its credit rationing. The discount rate was fixed at 10% after the stabilisation, but was then much below the rates of the private banks. Even when it was lowered in Feb. 1925 to 9%, in Jan. 1926 to 8% and in March 1926 to 7%, there remained an abnormal divergence between the official rate and the rates for private bank credits. By degrees, however, these rates have tended to come closer together.

The difficulties in the way of credit policy are enhanced by the restriction of the pre-War freedom of the Reichsbank in the control of its note issue, since the public funds, the reparation account and the foreign credits are more or less outside the direct influence of the Reichsbank, and are liable to lead to the withdrawal of considerable quantities of notes. The requirements of modern currency policy therefore compel the Reichsbank to watch most carefully the movement of the whole volume of purchasing power and its influence on prices, wages and other economic indices. It is incumbent on it to take or initiate the necessary measures to organise the money and capital market on sound lines, to encourage the formation of capital, and to secure the most economic use of all the available capital, including credits raised in foreign countries.

The Reichsbank augmented its gold holdings from less than 500,000,000 marks in 1923 to about 1,500,000,000 reichsmarks at the end of April 1926. The holdings of gold and liquid assets available for cover amount to 60% of the Reichsbank notes in circulation, but this proportion is not a decisive basis for credit policy as the circulation of Rentenbank notes has to be taken into consideration as well. From the middle of 1925 the total money circulation at the end of each month was in the neighbourhood of 5,000,000,000 marks. The total volume of private credit given by the Reichsbank, the private note banks, the Rentenbank, and the Gold Discount Bank, and including bills rediscounted by the Reichsbank to other bodies amounted in 1925 to about 3,000,000,000 reichsmarks.

After the stabilising of the currency German industry and commerce passed through a severe crisis, and thus heavy burdens were imposed on the Reichsbank as the guardian of the currency. In spite of these difficulties, it proved possible to maintain the value of the reichsmark, and from the beginning of June 1924 onwards all demands for foreign exchange were fully satisfied. It is not yet possible to foresee when the existing restriction on a free gold currency in Germany will be removed. In any case the fact that foreign exchange is available without limitation in exchange for Reichsbank notes is equivalent to the effective redemption of Reichsbank notes in gold. (K. No.)

GHENT, Belgium (*see* 11.919), had a population in 1923 of 163,877, and including the suburbs of Ledeberg, Ghentbrugge and St. Amand of 212,096. The city measures some 16 m. in circumference, much room being taken up by nurseries and gardens, for Ghent has become an important horticultural centre, especially for the cultivation of flowers under glass. Linen weaving has greatly developed, and schools of industry and mechanics have been established. A great international exhibition was held in 1913 in a Palais des Fêtes, specially built in the Parc de la Citadelle. The old cast-iron steeple of the belfry was rebuilt in 1913; subsequently most of the copper work from the new one was removed by the Germans. The hospital and almshouses for old men have been removed from the ancient Byloke, which has been fitted up to house the archaeological museum, previously in the old Carmelite church. The panels of the famous "Worship of the Lamb" by Hubert and Jan Van Eyk, dispersed since 1816, were brought together again in 1920 under the provisions of the Treaty of Versailles. A plaque in memory of Edith Cavell has been fixed on an inn, De Stad Ouden Aerde, where she stayed shortly before her arrest, and a memorial to the inter-Allied dead was unveiled in the cemetery in Oct. 1924. A new lock at Terneuzen enables vessels up to 26 ft. draught to pass at any tide into or out of the canal between that port and Ghent.

Ghent was in the hands of the Germans from Oct. 1914 till Armistice Day, Nov. 11 1918. The west part of the town suffered some damage in the final operations. The Germans published there the *Vlaamsche Post*, an organ professing Flemish sympathies and advocating the partition of Belgium, and made determined efforts to transform the University of Ghent into a purely Flemish institution, in order to widen the breach between the Flemish and Walloon elements. The university was reopened in Oct. 1923.

GIARDINO, GAETANO (1864–), Italian soldier, was born at Montemagno, Italy, Jan. 24 1864. He joined the army in 1882 and saw service in Eritréa (1889–94) and in Tripoli (1911–2). On Italy's intervention in the World War he was appointed chief of staff to the II. Army and was promoted brigadier-general in Aug. 1915. In June 1916 he was given command of the 48th Brigade and played an important part in the attack on Gorizia. In June 1917 he was promoted lieutenant-general but a few days later was chosen Minister of War and made a senator. He held office until after Caporetto, when he was appointed assistant chief of staff to the new commander-in-chief, Gen. Diaz. In April 1918 he was given the command of the IV. Army in the Grappa sector. At the battle of Vittorio Veneto (Oct. 24–Nov. 3 1918) he delivered a general attack on the Austrian lines and after a hard struggle forced the enemy to retreat. In 1919 he was promoted *generel d'esercito*. In Sept. 1923 as the Govt. of Fiume was unable to carry on, Giardino was sent to take charge of the town, where he remained until its annexation by Italy under the terms of the treaty between Italy and Yugoslavia in Jan. 1924.

GIBBONS, JAMES (1834–1921), American Roman Catholic cardinal (*see* 11.936), in 1916 published *A Retrospect of Fifty Years*. He died in Baltimore March 24 1921.

GIBRALTAR (*see* 11.938) has been largely increased in strength as a naval base; with the extension of the mole the deep harbour has an area of 260 ac. and affords anchorage for the largest ships. It was of great importance during the World War as a coaling station and port of call.

In 1922 an executive council was established, but all legislative power remains with the governor. A city council has replaced the board of sanitary commissioners, and currency notes have been issued by the local authority since 1913. Gibraltar is one of the most closely populated places in the world (9,888 to the sq. m. in 1921), but it is not unhealthy, the death-rate in 1921 being 17 per thousand. The population in 1924 was 20,638: 17,160 civilian, 2,932 military and 546 naval. There is a regular motor-omnibus service to La Linea, which has grown considerably and has a population of 63,000. A cross of sacrifice, in memory of those who died and were buried at Gibraltar during the World War, was unveiled in 1922, and a War Memorial in 1923. In 1915 a second reservoir was excavated, and the construction of another is contemplated. The Exchange in Commercial Square, which was burnt down in 1919, was rebuilt and opened in 1922. A public recreation ground was opened above the military school in 1920. The signal station on the summit of the rock has been dismantled. Since 1910 Gibraltar has been a Roman Catholic bishopric, independent of the Spanish hierarchy and subject directly to the Vatican.

GIDE, ANDRÉ (1869–), French essayist and novelist, was born in Paris Nov. 21 1869. Educated at the École Alsacienne and the Lycée Henri IV., he began his literary career with the *Cahiers* and the *Poésies d'André Walter* (1891–2). His first success was followed by a series of works resembling philosophical *causeries* in which an introspective method and great delicacy of expression were combined in an original manner. His dramatic works and criticism are characterised by the same sureness of touch and individual grace. He is considered one of the finest stylists in contemporary French literature, and exercised considerable influence outside his own country. As a novelist, however (as in *Les caves du Vatican*), he was less successful; he is more at home in the easy, discoursing flow of an essay.

Gide's works include: *Le voyage d'Urien* (1893); *Paludes* (1895); *Les nourritures terrestres* (1897); *Le traité du Narcisse* (1899); *Le Prométhée mal enchaîné* (1899); *L'immoraliste* (1902). Criticism: *Lettres à Angèle* (1900); *Prétextes* (1905). Drama: *Saul* (18 *Le roi Candaule* (1898); *Les caves du Vatican* (1911); *Isabelle* (19 *La symphonie pastorale* (1919); *Dostoievsky* (1923, tr. 1925); *Les f Monnayeurs* (1926).

GIDE, CHARLES (1847–), French economist, was b June 29 1847 at Uzès (Gard). Educated at the Collège d'U he entered the faculty of law of the University of Paris. He ea took up the study of economics and became professor of politi economy, first at Bordeaux, then at Montpellier, and from 1 to 1920 at the University of Paris. He is the author of one of best introductory treatises on political economy, *Princi d'Economie Politique*, first published in 1884 and since transla into English and other languages, and is joint author with fessor Rist of an excellent work on the history of economic theo *Histoire des Doctrines Economiques* (3rd ed. 1920). Gide devo a great deal of time and energy to the encouragement and therance of the co-operative movement in France, and wr largely on this question. Professor Gide enjoys a wide meas of esteem amongst scholars in other countries, not only as eminent economist, but also on account of his unremitting deavours to maintain and promote harmonious internatio relations and especially to preserve co-operation amongst int lectual workers in different countries. (*See* FRANCE.)

GILBERT, CASS (1859–), American architect, was b at Zanesville, O., Nov. 24 1859. He studied at the Massach setts Institute of Technology and in 1883 began his career as architect in St. Paul, but subsequently moved to New Yo He became perhaps most widely known as the architect of Woolworth building in New York, which has 57 stories and 760 ft. in height, and, with the exception of the Eiffel Tower Paris, the tallest structure in the world. Other buildings signed by him include the Minnesota State Capitol, St. Pa the Endicott building, the Dayton avenue church and St. Cl ent's Episcopal church, in St. Paul; the United States Cust House and the Union Club, New York; the Brazer building the Suffolk Savings Bank, Boston; Art building and Festi Hall (for the Louisiana Purchase Exposition), and the Cen Public Library, St. Louis; Ives Memorial Library, New Hav Conn.; Public Library, Detroit. He also drew the plans for university of Minnesota and for the university of Texas. was appointed by President Roosevelt a member of the Cou of the Fine Arts; and by President Taft a member of the tional Commission of Fine Arts, being reappointed by Preside Wilson. In 1926 he was appointed design architect for the posed bridge over the Hudson river at New York City.

GILBERT, GROVE KARL (1843–1918), American geolog (*see* 12.7), died at Jackson, Mich., May 1 1918.

GILBERT, SEYMOUR PARKER (1892–), American law and financial expert, was born in Bloomfield, N.J., Oct. 13 1 He graduated from Rutgers College in 1912, and in the same ye entered the Harvard Law School, obtaining the LL.B. degre 1915. After admission to the New York Bar, he practised New York City from 1915 to 1918. In the latter year, on the tiative of R. C. Leffingwood, a former Associate Secretary the Treasury, he joined the War Loan Staff as counsel. In J 1920 he became assistant secretary (later under-secretary) the Treasury in charge of fiscal affairs. He resigned Nov 1923, and became agent-general for Reparation payments un the Dawes plan Oct. 31 1924.

GILBERT, SIR WILLIAM SCHWENK (1836–1911), Brit playwright and humorist (*see* 12.9), was drowned at Har Weald, Middlesex, May 29 1911. His play, *The Hooligan*, produced a short time before his death.

GILBEY, SIR WALTER (1831–1914), British wine merch (*see* 12.11), died at Elsenham Hall, Essex, Nov. 12 1914.

GILDERSLEEVE, BASIL LANNEAU (1831–1924), Ameri scholar (*see* 12.12), died at Baltimore, Md., Jan. 9 1924.

GINER DE LOS RIOS, FRANCISCO (1840–1915), Spanish ph osopher and jurist, was born in Ronda (Andalusia) Oct. 10 184 He graduated in Granada, and in 1867 went to the Universi of Madrid as a professor of jurisprudence and there came un the influence of Prof. Sanz del Rio, Krause's famous discipl cordance with his belief that philosophy should have a con- influence on practical life, he devoted himself to the educa- question. Twice Giner resigned his chair, together with l of his colleagues, in a stand for liberty of thought in the rsity against a reactionary government, and was twice ated. He helped to found the Institucion Libre de Ense- ., an educational institution which did much to improve ing methods in Spain, by the application of philosophical ht to the problems of education. He many times refused on to the Cortes, and in 1873 declined a post in the Gov- ent. His greatest influence was personal and direct, for he born teacher, a man of refined sensibility, pure in his life his ideals.

er published several volumes of essays—literary, educational, ophical and religious—as well as *Lecciones Sumarias de ogia* (1871); *Psicologia; Idea del Derecho*, with Alfredo Calderon, from the German of Röder (1885); *Resumen de Filosofia del io*, with Alfredo Calderon (1898); and other works. A complete n of his numerous works was undertaken a year after his death. S. de Madariaga, *The Genius of Spain* (1923).

ISBURG, CHRISTIAN DAVID (1831–1914), British Hebrew ar (*see* 12.29), died in London March 7 1914.

LITTI, GIOVANNI (1842–), Italian statesman (*see*). The elections of 1909 returned a strong Giolittian ity, but Giolitti as Premier found himself faced with the sity for renewing the steamship conventions which were to lapse. The Bill presented by his Cabinet on this subject pen to much criticism, having been designed to conciliate cting political interests rather than to solve the actual em. The vigorous attacks of the Opposition, led by Sonnino, induced Giolitti to adjourn the debate until tumn, when, the Cabinet having been defeated on a point cedure, he resigned (Dec 2). But he continued to play an and in fact dominant part in Parliamentary politics, for ajority of the Chamber and of the Senate, being thoroughly tian, the Sonnino Ministry and that of Sig. Luzzatti succeeded it only remained in power at his discretion. in March 1911 Luzzatti resigned in consequence of the e vote of the Radicals and the resignation of its two Radical ers, Giolitti was again called upon to form a government ch 31).

e chief event of his fourth Cabinet was the Libyan War. nally he was not enthusiastic over the African enterprise, ntroduced new and, to him, unaccustomed and unwelcome s into Italian political life; but he realised that public on demanded it and he did not care to run counter to the nt. He was criticised by the vestals of constitutional ion for having declared war without consulting Parlia- and for not having summoned it until several months later. ng the campaign, he was, moreover, severely blamed on round that he acted as though the war were merely an of internal politics and party combinations. When peace concluded fresh elections were held on the new franchise ntroduced by the Cabinet, which raised the electorate from ,000 to 8,000,000 votes (Oct. 26–Nov 2 1913); although a tian majority was again returned, his opponents, not only g the Socialists, but also the constitutional parties, were more numerous, and he felt that opposition to his rule was ng in the country at large even more than in Parliament. arious awkward problems which now faced the Government he divisions among its own supporters induced him to the opportunity of a hostile vote by the Radical group to (March 10 1914).

en the World War broke out his attitude was favourable to solute neutrality of Italy, as he believed that his country's sts lay in not siding with either group of belligerents, and e eve of Italian intervention he made an attempt, by using rsonal hold over the Parliamentary majority, to upset the dra Cabinet, but it was frustrated by an uprising of public n in favour of the war. During the progress of the cam- he avoided public affairs, although he assumed a Cassandra- ttitude in all his utterances, and his henchmen in the Press frankly "defeatist." He consequently lost his influence over the bulk of public opinion and in many quarters was regarded as little better than a traitor. But after the Armistice the unsatisfactory consequences of the peace negotiations, the heavy burden of suffering and loss caused by the War, and, above all, the disputable internal policy of the Nitti Cabinet, which was accused of handing the country over to the Bolshevik Socialists, brought about the return of Giolitti.

When Nitti was forced by the impossibility of governing the country to resign for the third and last time on June 9 1920 a new Giolitti Cabinet was the inevitable alternative. He succeeded by June 15 in forming a Cabinet which comprised a number of non-Giolittians of all parties, but only a few of his own "old guard," so that he won the support of a considerable part of the Chamber, although the Socialists and the Popolari (Catholics) rendered his hold somewhat precarious. His policy of inactivity during the occupation of the factories by the workmen organised by Socialist leaders in Sept. 1920 provoked the indignation not only of the manufacturers but of all the middle-class. He appears to have acted under the impression that the Socialists were much stronger than they really were, and therefore gave them a free hand with the object of avoiding bloodshed, and also perhaps with that of proving to the workmen that they could not run industry without the capitalists and the technical experts. When he realised the strength of the national reaction, he allowed the Fascists free rein to re-establish order and practically exercise many of the functions pertaining to the Government, while he assumed an attitude of Olympic calm and posed as being *au-dessus de la mêlée*, so as to avoid compromising himself with any party.

In foreign affairs Giolitti succeeded in achieving a solution of the Adriatic problem less unsatisfactory than most of the previous proposals of the annexation of new provinces under the peace treaties and of the altered state of public opinion on internal policy, he dissolved the Chamber on April 7 1921, and was confirmed in power by the elections on May 15. But he resigned with his Cabinet at the end of June, being succeeded as Premier by Signor Bonomi.

He played no part in the subsequent events, until at the time of the march on Rome he was one of the statesmen who advised the Premier Signor Facta to resign. On the advent of the Fascist Govt., he expressed his approval of it and instructed his followers to support it. At the elections of 1924 he presented a list of his own in Piedmont, which was not in opposition to but independent of the Government, and in an election speech he attributed many of the achievements of Fascism to his own policy. After the Matteotti affair he definitely went over to the Opposition but did not leave the Chamber, and his hostility remained fairly moderate. In 1922 he published two volumes of memoirs entitled *Memorie della Mia Vita*. (L. V.*)

GIRL GUIDES, a movement for the training of girls based on similar principles to those of the Boy Scouts (*q.v.*). Its aims are: to develop good citizenship; to train girls in habits of observation; obedience, self-reliance, loyalty and thoughtfulness for others; to teach useful service and handicrafts; to promote physical development; to make them capable of keeping good homes and bringing up their children properly. The training runs mainly in four directions: character and intelligence; homecrafts and handicrafts; health and physical development; service for others. The movement is non-political and interdenominational.

Origin and History.—After the Boy Scout movement had been founded by Sir Robert Baden-Powell girls in different places began to copy its activities, and banded themselves together as Girl Scouts. To meet the needs of these girls, Sir Robert and his sister, Miss Agnes Baden-Powell, in 1910 started a separate movement for girls, and gave it the name of Girl Guides. The movement received a charter of incorporation in 1915 and a royal charter in 1923. Princess Mary became president in 1920. Lady Baden-Powell (wife of the Chief Scout) was elected Chief Guide in 1918.

Organisation.—The governing body of the Girl Guides is the council, which meets annually and elects an executive of nine members. Sir Robert Baden-Powell is permanent chairman of the executive. The executive appoints county commissioners, who in turn appoint division and district commissioners to assist them. Under the latter come the captains, who do the actual training of the girls, grouped into companies. A guide company consists of from eight to 40 girls, and is subdivided into patrols, each under the charge of a patrol leader, who is herself a guide. She is either appointed by the captain or elected by the other guides, and has entire authority over her patrol, and entire responsibility for its conduct and efficiency. The affairs of the company are managed by the court of honour, consisting of the patrol leaders, who meet periodically, under the chairmanship of the captain. A company usually meets once a week, and goes to camp, if possible, for one week in the year.

Membership.—To become a member of the guide movement a girl or woman has to be enrolled. She makes a three-fold promise: to do her best to do her duty to God and the King; to help other people at all times; to obey the guide laws. There are 10 guide laws, namely: a guide's honour is to be trusted; a guide is loyal; a guide's duty is to be useful and to help others; a guide is a friend to all and a sister to every other guide; a guide is courteous; a guide is a friend to animals; a guide obeys orders; a guide smiles and sings under all difficulties; a guide is thrifty; a guide is pure in thought, word and deed.

After enrolment the members of the movement have the right to wear the guide uniform, navy blue with different badges to denote rank or proficiency. The badge of the guides is a trefoil, their motto is " Be Prepared." There are three main branches: the Brownies, aged from 8 to 11, the girl guides, aged from 11 to 16, and the senior guides, from 16 upward, who may be either rangers or sea guides. The officers are called guiders; they can receive training in guide methods at Foxlease Park, Lyndhurst, Hants, England, which was presented to the organisation by Mrs. Archbold Sanderson in 1922.

The guide movement has spread to the British Dominions and other countries. In 1924 a World Camp, attended by some 1,100 guides, from over 30 different countries, was held at Foxlease. At the end of 1925 there were some 613,209 members throughout the world. The Headquarters of the Girl Guides are at 25, Buckingham-Palace Road, London, S.W. The movement is financially self-supporting.

BIBLIOGRAPHY.—Sir R. Baden-Powell, *Girl Guiding, the Official Handbook* (1918); *The Brownie Handbook* (1920); *Annual Report*, Official (1925); *Rules, Policy and Organisation* (1926). See also *The Girl Guides' Gazette.* (M. Mo.)

GIRL SCOUTS: *see* BOY SCOUTS.

GLADDEN, WASHINGTON (1836–1918), American divine (*see* 12.63), died at Columbus, O., July 2 1918.

GLASGOW, Scotland (*see* 12.80), enlarged its boundaries in 1912 by the inclusion of Govan, Partick, Pollokshaws and several suburban districts, making it again the second city in Great Britain in population, and increasing its area from 12,975 to 19,183 acres. The number of wards was increased from 26 to 37, and the membership of the corporation from 80 to 113—three representatives of each ward, and two ex-officio members (the dean of guild and the deacon convener of the trades). Since 1918 Glasgow has sent 15 members to Parliament. A further ambitious scheme of enlargement of the burgh was promoted after the World War, owing to the congested state of the city and the fact that many of the housing schemes were situated outside the boundaries. It involved the incorporation of 22,000 ac., and met with opposition from adjacent counties and burghs; eventually, by an Act of 1925 (coming into force in May 1926), about half the proposed area, taken from Renfrewshire, Lanarkshire and Dumbartonshire, and including the important Yoker area near Clydebank, was incorporated. The population in 1921 was 1,034,174 and the rateable value in 1925 £11,040,693.

The Rent Strike.—Housing conditions have been extremely bad, and the new houses erected insufficient to accommodate even the normal increase in population; there has also been much unemployment. A legal campaign by the tenants, contesting the validity of notices of increase of rent under the Increase of Rent (Restriction) Acts, served without previous notice to quit, was supported by the decision of the House of Lords in a test case (*Kerr* v. *Bryde*) in 1922, and in the following year an amending Act to regularise the position was passed. Many tenants, however, refused not only the increased rent but any rent at all, and demanded a return to the pre-War standard. A large number of eviction orders were granted in 1924 and early in 1925, but their execution was rendered impossible in most cases by the violent tactics of the tenants. In June 1925 the unrecovered rents represented nearly a year's rental of tenanted houses in the borough, and the local authorities were seriously embarrassed by the nonpayment of rates. A rent commission was then appointed which recommended the simplification of the form of notice requi
and other reforms in the working of the Increase of Rent (
striction) Acts.

Public Buildings, Parks.—Additions to the municipal bu
ings, connected by two bridges with the older buildings, w
completed in 1923. The Mitchell library, the largest of the pu
libraries, was removed to North street in 1911; 25 branch lib
ries have been established. Since 1913 14 new chairs have b
founded in the university, and the western sections were be
extended in 1926, to provide new classrooms and a memo
chapel. The block of the Royal Infirmary which contained
famous ward in which Lord Lister first applied the use of a
septics was pulled down in the course of an extension schem
1924, in spite of widespread opposition. A new building for
Ear, Nose and Throat Hospital was opened in St. Vincent Squ
in 1926. In 1915 the corporation bought the Balloch Ca
estate, of which 200 ac. were made into the Loch Lomond P
Other purchases were the Linn Park of 180 ac. (1919); and
Ruchazie and Frankfield Park of 300 ac. (1920). The Newla
Park was given in 1913, the Glenconner Park in 1914 and
Dawsholm Park in 1920. In 1911, 121 ac. of the grounds
Pollok House were given for use as a public park for a perio
10 years. Statues of Lord Kelvin (1913), Lord Roberts (19
Thomas Carlyle (1916) and a war memorial to men of the Ca
ronians have been erected in Kelvingrove Park; and a war
morial cenotaph was unveiled in George Square in 1924. Kel
grove and College United Free Church and Kelvin Hall, a la
building used for exhibitions, etc., were destroyed by fire in 19

In 1924 a beginning was made with the provision of furt
dock accommodation on an area of land acquired by the Cl
Navigation Trustees between Shieldhall and Renfrew. Contra
were signed for the construction of railway lines and a road
the new dock area from the new trunk road of the Glasgow
poration scheme. A big electric generating station was ope
at Dalmarnoch Bridge in 1920, and the largest gasworks of th
kind in Great Britain were completed at Govan in 1921.

GLASGOW, UNIVERSITY OF (*see* 12.82).—The following
new chairs have been founded since 1907: Mining, medic
(Royal Infirmary), obstetrics and gynaecology (Royal In
mary), surgery (Royal Infirmary), pathology (Royal Infirma
Scottish history and literature, French, German, organic che
istry, physiological chemistry, bacteriology, mercantile l
applied physics, theory and practice of heat engines, electri
engineering, public health, medical paediatrics, Italian, Spa
and accountancy. New lectureships have been instituted
Celtic, psychology, social economics, geography, dermatolo
clinical medicine, clinical surgery, clinical obstetrics, disease
the throat and nose, diseases of the ear (Royal Infirmary),
teria medica and pharmacology, electrical diagnosis and the
peutics, Russian, clinical tuberculosis.

New Buildings.—Considerable progress has now been ma
with the extensions of buildings which were postponed owing
the World War. The new zoology building, erected at a cost
about £112,000, is now occupied, and the building which is
complete the west wing and includes the War Memorial Cha
is in course of erection. The estimated cost of this building
about £122,000.

The students themselves have been active in furthering
student welfare scheme and, including grants from the Go
the Carnegie Trust and the proceeds of a bazaar, a sum
about £85,000 has been collected. Out of this fund there ha
been provided a union for women students and the necessa
expenditure to convert the houses presented by Lord Mac
and Mr. Lawrence MacBrayne into men students' hostels
the house presented by Mr. J. M. Robertson into a wome
hostel. The money, about £12,000, necessary for the erection
a pavilion on the athletic ground at Westerlands—which is
open—has also been provided out of this fund. Grants have
been made to the athletic club and the boat club. The acco
modation of the present union for men students is quite ina
quate. A site for a new building has been secured and steps
being taken to secure the remainder of the necessary funds.

r Donald McAlister became principal in 1907, and in the ersity itself, as outside in university matters generally, has cised a remarkable influence.

Students

Session	Men	Women	Total
10–1 . . .	2,108	682	2,790
15–6 . . .	1,163	658	1,821
20–1 . . .	3,576	1,132	4,708
23–4 . . .	3,275	1,419	4,694
24–5 . . .	3,069	1,529	4,598

ıe figures for session 1910–1 represent a normal year; 1915–6 a year. The figures for the other years show the large increase in ıumbers of students which has taken place since the War.

LASS, CARTER (1858–), American politician, was born ynchburg, Va., Jan. 4 1858. He received his education in Lynchburg schools and learned the printer's trade, which he wed for several years, eventually becoming proprietor of Lynchburg *Daily News* and *Daily Advance*. He was elected ne Virginia State Senate for two terms (1899–1903) and was ember of the State Constitutional Convention in 1901. He elected in 1902 to the national House of Representatives, thereafter was continuously re-elected until his resignation 918. As chairman of the House Banking Committee he was ve in framing and passing the Federal Reserve Bank Law. 918 he entered President Wilson's Cabinet as Secretary of Treasury. Under his guidance the fifth Liberty Loan was ted in April 1919. In Nov. 1919 he resigned, following his ointment and subsequent election to the United States Sen- In 1924 he was elected for the term 1925–31.

LASS (*see* 12.86).—Since 1910 considerable developments in glass industry have occurred, both in the glass produced in the varieties of glass manufactured. In the following le attention is, of necessity, given to the British glass inry. When the War drew attention to the British position in ect of glass generally, it was in the direction of scientific sware and special glass for certain industries, that the ciencies were realised. (*See* also OPTICAL GLASS.)

boratory Glass.—Before the War nearly all the glass and glass ratus used in laboratories throughout the United Kingdom was ined from abroad. The main kinds of glass required for labora- purposes may be grouped thus: Soft glass for tubing, and for a ber of articles and vessels where the highest resistance to chemaction is not required; glass highly resistant to chemical action; hard glass for combustion tubing; glass for thermometers.

ft Glass.—Such a glass must be soft enough to be readily worked flame, and must stand prolonged heating without showing the ges in appearance and working qualities generally described as trification. Before chemical glassware of foreign origin became tically universal in laboratories, vessels and apparatus in great ety were made from lead glass. The advantages claimed for non- glass as a material for laboratory apparatus have been proved, there is no likelihood of a return to lead glass, which, however, be made of such high resistance to the action of water, and of y solutions which also abstract alkali from glass, that in some ial cases vessels made from it are only surpassed by silica in tance to chemical change.

the early days of the War it was recognised that there would be rious shortage of laboratory vessels. A simple sodium-calcium- ate glass was unsuitable since tubing made from it is practically ess to workers in laboratories. The immediate advance made the addition of alumina, either as such, or preferably in the of felspar. The use of alumina for retarding devitrification and rendering a glass workable in the flame was known in Great ain, and at least three British manufacturers had for some years luced glasses containing various percentages of alumina up to t 10%.

sodium-potassium-calcium-aluminium-silicate type of glass has t satisfactory general properties. Arsenic is not permissible, and only constituent other than those indicated which might be ed was a small amount of manganese dioxide, to disguise the green ur due to the presence of iron in the material used. The formula n here shows the approximate composition of a batch mixture essed in percentages of silica and oxides of the metals in the ous ingredients of the batch: SiO_2, 68; Al_2O_3, 4; CaO, 7; K_2O, Na_2O, 14·5. This yields a good glass, soft enough for flameking while possessing good durability.

se of Potash Felspar.—It became necessary to conserve supplies otassium compounds, of which the amounts that could be apioned for use in glass manufacture were sufficient only for the production of certain optical glasses. To some extent nitre was available and was used. Potash felspar, which for long had been an ingredient in certain glasses, was a convenient form of aluminium compound for introducing alumina. The amounts of this material employed varied between wide limits, and glasses of good working qualities were obtained.

Borax.—Varying proportions of borax were employed, and in this way sodium-potassium-calcium-aluminium-boro-silicate glasses of good working qualities and of marked durability were produced, which met many of the requirements of laboratory workers. The boro-silicate glass possessed many desirable properties when the glass was well made and the necessary technical skill had been acquired. It failed, however, when used for X-ray tubes. A glass of the general type indicated in the formula above is quite suitable for such work, and hence X-ray bulbs and tubing can be made from it in the course of working a pot for a variety of other articles.

Experience shows that the best type is on the lines of the formula given, and that the presence of notable proportions of the oxides of aluminium and potassium are essential. Potash felspar has been mentioned as a convenient source of alumina, and part of the alkalies may be usefully added as nitrates. In general, all the materials of the batch mixture should be as pure as can be obtained commercially, so that the composition of the glass may depart as little as possible from that which it is intended to have, and which has been proved to give satisfactory results. One or two remarks which are relevant for almost all glasses may be made here.

Anhydrous Materials.—As far as it is possible to obtain and to store them, all the substances for a batch mixture should be free from water. A glass made from anhydrous materials often differs from one calculated to give the same composition finally, but produced from a wet batch, or from one containing an ingredient having a notable proportion of combined water. In addition to some lack of general stability, the glass from a wet batch may show a greater tendency to devitrification when heated in a flame or by radiation. The amount of water left in a glass may be very small, but it affects the behaviour of the glass. However, the action of water to effect change in glasses either during their production or on subsequently heating them is an advantage in respect of the production of certain coloured glasses and apparently of some opal glasses.

Homogeneity.—All glasses for laboratory use should be made in such a way as to secure the greatest possible homogeneity. As a general rule, the long-founding so much insisted upon by many experienced glass manufacturers cannot be dispensed with if the nicest possible refinements of a good glass are to be realised. Stirring to secure homogeneity is a necessary operation in making optical glass. It is not customary to stir glass for laboratory use, but such glass would be improved by being stirred if it were economically possible.

Annealing.—The subject of annealing has, in recent years, been given much attention, and several investigations have been carried out. Results of much interest and importance have been obtained, dealing with the conditions for removing strain in glass and with the problem of annealing, both from the theoretical and a practical point of view. These results emphasise the importance of thoroughly annealing any glass articles which are required to withstand marked changes of temperature, and of arranging that any vessels, etc., which in the course of production are re-heated locally, shall be re-annealed. Tubing is not customarily annealed as part of the process of manufacture, but for certain purposes, notably with tubes which are to be ground, it is an advantage to anneal them.

"Resistance" Glass.—Laboratory glassware, to deserve this description, must possess great stability, and must part with only minute traces of any of its ingredients when it is exposed to the action of the majority of solutions and liquids used in a chemical laboratory. The chief varieties made can be included in two types: one containing compounds of zinc and the other free from this metal. In neither type is the inclusion of arsenic or antimony considered to be permissible.

The following formulae, illustrative of these two types, give approximate proportions for batch mixtures expressed in percentages of the oxides contained in the various ingredients of a batch:—

(A) SiO_2 . . .	66	(B) SiO_2 . . .	66
B_2O_3 . . .	8	B_2O_3 . . .	9
Al_2O_3 . . .	9	Al_2O_3 . . .	2·5
CaO . . .	5	ZnO . . .	8
MgO . . .	1	MgO . . .	5
Na_2O . . .	8	Na_2O . . .	9·5
K_2O . . .	3		

Adjustments of the proportions given can be made to suit different furnaces and also to fit in with the amount of broken-up glass from previous meltings (cullet), which is incorporated in the batch. Of these two types of resistance glass, (A) requires a rather higher temperature in the making and on the whole presents more difficulties than (B). It has also a somewhat higher coefficient of expansion, is less liable to withstand sudden changes of temperature and has been made of very high chemical resistance and of satisfactory behaviour when quickly heated or cooled through a greater range of temperature than it would usually be exposed to in a laboratory. It is probably fair to give preference, on the whole, to glass of type (B) as inherently more capable of withstanding sudden changes of temperature, and, being the easier to make, there is less likelihood with vessels made from it of mishaps due to imperfect manufacture. Whichever class of glass is chosen, all vessels and apparatus made from it need thorough annealing.

Combustion Tubing.—Tubing of very hard glass is essential for many laboratory experiments, and is largely used in the analysis of carbon compounds by combustion, but in tubing of various diameters it is required for a number of other purposes. The general composition of Kavalier's combustion tubing is indicated by the following percentages to the nearest whole numbers: SiO_2, 78; CaO, 8; K_2O, 12; Na_2O, 2. Glass of this kind served many useful purposes in laboratories, but it was difficult to use in a blowpipe flame. The Jena glass which took its place possessed greater plasticity over a longer range of temperature. During the War very hard glass tubing was much needed, and as the result of experiments on a laboratory scale and in glass works, tubing of a type similar to the Jena combustion tubing was produced. With regard to hardness and suitability for working in the flame it fulfils its purpose most satisfactorily. Unlike the pre-War glass, it does not show anything like the tendency to become opal when heated for a long time. The following is the composition for a batch mixture, given as for other glasses in the percentage of oxides: SiO_2, 68·5; B_2O_3, 5·5; Al_2O_3,6; CaO, 8; BaO, 6·8; Na_2O, 3·2; K_2O, 2. With this glass there is not much latitude allowable if the full hardness of the glass is to be realised and difficulties in manufacture are to be avoided. The glass requires a high temperature for its successful production.

Thermometer Glass.—The manufacture of thermometers of all kinds has been carried on in Great Britain for many years, and British capillary tubing of high quality and technical perfection made both from lead glass and from various other types of glass, has been in constant demand. Jena thermometer tubing was largely used by British thermometer makers. During the War very great numbers of thermometers were called for, the greater proportion being for medical purposes, but many also for scientific and industrial use. Manufacturers of glass produced tubing to meet the demand, in lead glass, for the production of which they were ready and pre-eminent, and in other varieties of glass having properties closely similar to two Jena glasses of high reputation. One of these can be used for thermometers, capable of standing high temperatures up to about 500° C., and the other is for more general application. The following formulae, given as for other glasses in percentages of oxides and with similar reservations, indicate the nature of batch mixtures for these types of glass:—

High Temperatures		Ordinary Temperatures	
SiO_2	73·5	SiO_2	67·0
B_2O_3	9·7	B_2O_3	2·5
Al_2O_3	5·8	Al_2O_3	2·7
Na_2O	11·0	CaO	6·5
		ZnO	6·7
		Na_2O	14·6

Vessels and Apparatus.—Scientific glassware may be broadly classified as furnace-made and as lamp-blown. The former is for the most part produced by blowing into moulds molten glass gathered from the furnace on a blowing-iron. Before the War, lamp workers for laboratory apparatus were few in number in Great Britain and were chiefly engaged either in making a comparatively small amount of apparatus to special design or in repair work. Glass for such apparatus is supplied to the lamp blower in the form of tubing, in the production of which, therefore, there had also been a great development.

For glass for miners' lamps, a glass withstanding rapid changes of temperature exceptionally well was necessary, since the lamp glasses are thick and the flame of the lamp may often touch them. There was an urgent demand for them early in the War. It was successfully met, and such glasses of British make are now produced in large quantities. Another glass on similar lines, but differing somewhat in composition, was prepared for the production of chimneys for incandescent and high-pressure gas illumination, paraffin lamps, etc. In addition to withstanding heat changes well such a glass must be markedly resistant to the chemical action of hot products of combustion. Both these glasses consist chiefly of alkaline boro-silicates having a high percentage of boric anhydride. They need a high temperature for their successful production in a homogeneous state. When well founded their low coefficients of expansion render articles made from them highly resistant to sudden variations in temperature over a long range.

Glass rods for half-watt electric lamps were required, to hold the thicker tungsten wires which support the filament of this metal. They had to be made specially, since no existing glass of British make capable of withstanding heat changes was also sufficiently reliable in respect of not cracking round the sealed-in wires. This glass in most cases involved also the production of special rods to join with it and with the stem of the lamp.

Other glasses were needed which, while making safe joints with ordinary laboratory tubing, etc., would hold platinum, copper, iron or nickel wires. Such glasses are often described as sealing-in enamels. Several of these have been made, and, generally spe
they are of the type either of a soft glass containing a high perce
of lead, or of one free from lead and containing a notable prop
of a fluoride, such as cryolite. The coefficient of expansion
glass, in relation to that of the metal wire used, has to be take
account.

Jars for Preserving Fruit and Meat.—Though numbers of thes
long been made in Great Britain, about 80% of the total n
used had been obtained from abroad. Great increase in th
duction of these vessels was required to meet the needs, enh
as they were by the War, and the necessity for more economi
duction led to a review of methods and to the adoption o
machinery.

Glassware for Medical Purposes.—The War caused a great in
in the demand, and very large quantities of vials, tubes, syr
graduated measures, etc., had to be made. Most of these co
produced from glass, and by methods familiar to manufact
but some requirements had to be met by investigation and e
ment before suitable glass was produced.

There was considerable increase during the War in the prod
of coloured glasses, *e.g.*, for spectacles to protect the eyes of the
numbers of men working at steel furnaces. Coloured glas
considerable variety were also wanted for other purposes, b
comparatively small amounts. Some of them needed investi
and a number of experiments before the conditions for their pr
tion could be determined.

Progress in the Use of Machinery.—The greatest advance i
economic production of certain types of glassware was in the dir
of the introduction of machinery and minor labour-saving d
which was only rendered practicable by concurrent improveme
the means for assuring a continuous supply of molten glass in
able condition to permit of the machines being run continu
The common practice in the past was to found the glass in p
direct-fired furnaces. There has been a gradual tendency for t
some of them being of very large capacity, holding as much
tons of molten glass, to take the place of the older pot fur
Those glasses which are only required in comparatively small
tities or of absolute purity, as in the case of optical glass, c
coloured glasses, and those liable to contamination from fu
gases, will still have to be pot-founded.

Automatic Machinery.—The development of machinery in
manufacture has been by gradual evolution. In many Am
factories, neither the raw materials nor the glass is handled a
stage during the progress of manufacture. Conveyors transf
raw material from the trucks to the storage bin; automatic wei
discharge the requisite quantity of material from the storage
a rotary mixer mounted on a trolley; another conveyor transfe
mixed batch to the batch storage bin in close proximity to the
ing end of the tank, for the ready release of the batch down a
at periodic intervals into the tank.

Types of Machines.—The types of machines may be conven
divided into the following groups: pressing machines for the
duction of tumblers, meat and jelly jars, bull's-eye lenses, tabl
and pavement lights; press and blow machines for all types of b
and many kinds of food containers; blow machines for el
lamp bulbs, lamp chimneys and similar articles; rolling mac
for plate glass, figured and ribbed glass and reinforced sheet for
and window glass, and for drawing tubes and rods.

There are many other types for miscellaneous purposes, incl
cracking-off machines for severing the fashioned article from
waste glass, employing multiple fine jets of flame which impin
the line of severance which is usually started by a short diamo
at the predetermined point: calibrating machines for accu
dividing measuring devices such as thermometers, burettes, pi
and cylinders; grinding and polishing machines for preparin
finishing the surface of plate glass; machines for forming the sto
of bottles and for grinding the seating in the neck of the b
flowing devices and feeding machines, to withdraw from the p
tank, by means of a gathering-iron, a sufficient quantity of m
glass to make the article required.

Press Machines.—A very limited number of types of articl
be made with a solid mould. Only such as have both an int
and external taper, the diameter being reduced in the directio
the movement of the plunger, are suitable. In all other cases
the ware has external shoulders or ornament, the mould mus
hinged. In semi-automatic and fully automatic machines the
ments of the plunger and mould are operated by compressed a

Refractories and Pots.—With the introduction of more eff
pot furnaces and tanks in which higher temperatures were re
it soon became evident that the question of refractories would
to be investigated in order that the pots, tank blocks and fu
parts, would stand up to the increased strain which was bein
upon them.

In so far as concerns the majority of types of optical glass, a
it were an economical proposition, for other glasses also, pots
porcelain nature or of a composition approximating in relative
portions of alumina and silica to kaolinite have given the most
factory results. In connection with the manufacture of optical
in America for war purposes it was found that a pot of the porce
type was the best suited to their purpose. In other directions

ble experimental work has been devoted to the production of
ɩy the ordinary casting and by the vacuum casting processes,
lso of pots from osmose clay. In each case results of great
se have been obtained.

: tendency has been to adopt the recuperative principle, in
there are two sets of channels or passages, one for the air
, and the other to carry away the hot products of combustion;
mperature of the air is raised due to interchange of heat by
ction through the common party wall of the channels. As the
f the secondary air and hot flue gases is constant in direction,
are, therefore, no reversing valves to be operated, as is the case
regenerative type, and it is claimed that the furnace can be
ained at a more even temperature in the former than in the

: recuperative type of furnace is producer-gas fired. The
:es, according to the designer, differ in respect of the disposition
ir elements; in one type both the producer and recuperators
:uated immediately below the furnace, and both the air pas-
and hot flue-gas passages are disposed horizontally, whereas in
er type the recuperators are at the sides, and the air passages
rtical whilst the flue-gas passages are horizontal. It is claimed
e latter type that glass from a broken pot can be more easily
with and is not likely to cause so much damage.

firing has not been installed to any extent in the glass industry
gland, and in very few, if any, cases has the furnace been de-
l specifically for oil fuel. During the first half of 1921 some
.l glass furnaces in England were fired with heavy oil.

ter results were obtained with the heavier grades of oil, and
'urnaces lend themselves more readily to this type of fuel. In
:se of pot furnaces the pots are liable to suffer on account of
:egular heating due to localised combustion.

ı result of efforts to improve the existing types of oil burners in
rection of better efficiency, etc., several oil burners are now on
arket, in some of which atomisation is effected by steam under
ıre. In others mechanical means and air pressure are utilised.
ugh more complete atomisation is obtained by the former means,
e burner utilising air pressure with some mechanical means for
ng atomisation gives more complete combustion, higher tem-
ıres and increased cleanliness without discolouration or de-
ıtion of the glass, due to the effects of the flame coming into
:t with it. Moreover, with oil fuel the temperatures can be
easily controlled.

ıealing.—Prior to the War in annealing optical glass an efficient
n of well-lagged electrically heated towers ensured a satis-
y result. In other types, however, a primitive, straight-
ʒh tunnel (usually coke heated) formed the lehr. It was exceed-
draughty and the glass was hurried through in all too short a
During the War, however, when the annealing needed to be
suspicion, close attention was devoted to the subject of im-
l lehrs. Considerable care was exercised to ensure efficiency
; operation. The site was well chosen, the system of heating
onsidered in relation to the necessity of a variation in the
ıum temperature according to the class of ware being annealed,
f a gradual fall in temperature after passing the hottest zone.
utions were taken to prevent draughts sweeping through the
nd so defeating the object of the operation. [See W. Rosenhain,
Manufacture (1919); H. T. Powell, *Glass Making in England*
)].

OEBEN" AND "BRESLAU."—The escape of the two
rs "Goeben" and "Breslau" from Messina on Aug. 6 1914
heir flight to Constantinople exercised a large influence on
ttitude of Turkey.

sition in Aug. 1914.—When the World War broke out the
ıs naval forces in the Mediterranean were as follows:—

TABLE I.

:ish forces under Vice-Adml. Sir A. Berkeley Milne:—
cruisers.—"Inflexible," "Indomitable," "Indefatigable"
ɩ2-in., 25 knots), 1st Cruiser Sqn., Rear-Adml. E. C. Trou-
lge; "Defence" (4 9·2-in., 10 7·5-in.), "Black Prince,";
uke of Edinburgh," "Warrior" (6 9·2-in., 10 6-in., 22 knots).
cruisers.—"Chatham," "Dublin," "Gloucester," "Wey-
ıth."
yers.—5th Flotilla, 16 Destroyers.
nch forces under Vice-Adml. Boué de Lapeyrère:—
ships.—One Dreadnought, six "Lord Nelson" type (4 12-in.,
)·4-in.), nine older battleships.
ıred cruisers.—Six.
yers.—24.
ian forces:—
ships.—Three Dreadnoughts, three "Lord Nelson" type.
trian forces:—
ships.—Three Dreadnoughts, three "Lord Nelson" type.
man forces under Rear-Adml. Souchon:—
cruiser.—"Goeben" (10 11-in., 25 knots).
cruiser.—"Breslau" (12 4-in., 25½ knots).

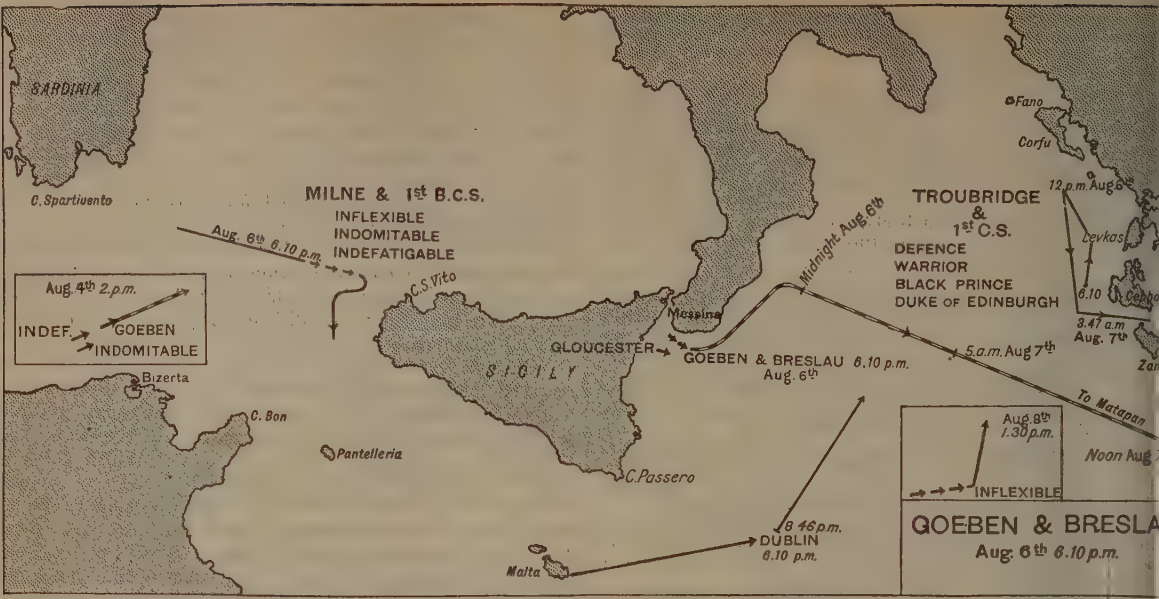
The original orders for the Mediterranean fleet in the event of war were to concentrate at Malta and watch the entrance to the Adriatic, but these were overridden by a series of Admiralty telegrams. The British fleet was at Malta on July 29. On the 30th, Adml. Milne received instructions that his first task was to assist the French in the transport of their troops and to bring the "Goeben" to action if she attempted to interfere. These instructions were sent without reference to the French commander-in-chief, who had not asked for assistance, and the two admirals remained unaware of one another's plans. On July 31 the Italian Govt. informed the British that it intended to remain neutral, a communication of great import, which did not reach the commander-in-chief. On Aug. 1 the "Goeben" and "Breslau" left Brindisi for Messina, the rendezvous decided on in 1913 under the terms of the Triple Alliance.

Search for the "Goeben."—On Aug. 2, at 2:45 P.M., Milne received further orders from home to shadow the "Goeben," watch the entrance to the Adriatic and remain near Malta himself. He accordingly took up his station that evening in the "Inflexible" off Malta, and at 9 P.M. Troubridge sailed with the "Indomitable" and "Indefatigable," the four armoured cruisers and four destroyers to watch the approach to the Adriatic. About 8 P.M. that evening, Milne had been given permission to get in touch with the French admiral, but received no answer to his signals and remained ignorant of the French plans. That night (Aug. 2–3) Milne heard of the "Goeben's" arrival at Messina, and, in answer to his request for instructions, was told by the Admiralty to maintain his watch on the Adriatic, but the "Goeben" was his objective and was to be followed and shadowed wherever she went.

Meanwhile, in Messina, Souchon had received the warning telegram about midnight Aug. 2; he stopped coaling abruptly and put to sea at 1 A.M. Aug. 3 with the intention of bombarding the Algerian coast. The "Chatham" was ordered to look for the "Goeben" in Messina, and passed through the Straits at 7 A.M. (Aug. 3), only to find the harbour empty. In order to locate the "Goeben" and protect the French route, Milne at 9:40 A.M. ordered Troubridge, then on his way to the Adriatic, to proceed west with the "Indomitable," "Indefatigable" and 1st Cruiser Sqn., leaving the "Gloucester" and destroyers to watch the Adriatic. This order was modified at 3:18 P.M. (Aug. 3), when Troubridge was sent back to the Adriatic with the 1st Cruiser Sqn., while the battle cruisers went on to the west, with orders to cruise between Africa and Sardinia. Milne was greatly handicapped all this time by his ignorance of the French dispositions, and received no information from home on this point. Souchon on his way to the African coast received news at 6 P.M. (Aug. 3) of the outbreak of war with France from the Italian wireless station at Vittoria, but held on his way. The Admiralty, having lost sight of the "Goeben," assumed that she was on her way to attack the Atlantic trade routes, and at 8:30 P.M. (Aug. 3) ordered the "Indomitable" and "Indefatigable" to proceed after her to Gibraltar at high speed. They were then south of Sicily and went off at 21 knots.

"Goeben" Sighted.—At 3 A.M. on Aug. 4 Souchon received from Nauen, the great German wireless station, the Kaiser's order to proceed to Constantinople. Deciding to finish his venture, he went on to the African coast, fired a few salvoes into Bône and Philippeville at 6 A.M. (Aug. 4) and made off. At 9:15 A.M. on his way East, he narrowly escaped meeting the French 1st Sqn., which passed him only 24 m. away. Then, by a stroke of good luck, the "Indomitable" and "Indefatigable" on their way westward ran right into him, 40 m. north of Bône, at 10:32 A.M. (Aug. 4). The battle cruisers turned to the east and followed him at 11,000 yards. Their guns were loaded and manned, but war was not declared and they did not fire.

The day was misty, the "Goeben" was at least two knots faster, and by 4:35 P.M. was out of sight. The Admiralty, where it was thought that the "Goeben" was going west, asked the Foreign Office to agree to her being engaged if she attacked French transports, and the order to do so was sent, but did not reach Milne till 5 P.M. Meanwhile he had received during the



afternoon the news of the Italian declaration of neutrality and an order not to approach within six miles of the Italian coast. Italy in her declaration of neutrality had claimed a six-mile limit, which had been accepted without demur. Belligerents were thereby debarred from committing acts of hostility within this limit, but no convention of international law debarred them from entering neutral waters. Italy had not asked for anything of the sort, and the restriction was cancelled on Aug. 6 at 7:46 P.M.; but its immediate effect was to debar Milne from passing through Messina Straits, thus preventing the immediate concentration of any forces he might station at the two entrances.

Meanwhile, the "Indomitable" and "Indefatigable" were still going east on the "Goeben's" track, and were between Sicily and Sardinia when at 6:30 P.M. (Aug. 4) they received orders from Milne to steer west and go slow, and turning round they abandoned the pursuit. In giving this order Milne was evidently influenced, partly by the idea of covering the French transport route, partly by the Admiralty injunction against approaching the Italian coast. He did not know that the French admiral had his whole fleet guarding the route between France and Africa.

Declaration of War.—The warning telegram reached Adml. Milne at 7:02 P.M. (Aug. 4) stating that the ultimatum would expire at midnight. When hostilities commenced at that hour (Aug. 4–5), the "Inflexible" was in Malta channel, steering west to join the "Indomitable" and "Indefatigable"; the "Goeben" was approaching Messina, and Troubridge with the 1st Cruiser Sqn. was about 60 m. west of Zante. The "Goeben" arrived at Messina at 4 A.M. on Aug. 5 and started to get in coal, but on the protest of the British consul difficulties arose and the work was slow. News of her arrival was sent that forenoon by Sir Rennell Rodd, British Ambassador at Rome, to London, and though it did not reach Milne from London till 5 A.M. on Aug. 6, he had already received warning of it from the "Gloucester" at 5:30 P.M. on Aug. 5 and also a report from Malta. At 11 A.M. on Aug. 5 he was off Pantellaria in the Straits of Malta, and proceeded to Bizerta, where the "Indomitable" was sent in to coal. A still more important piece of information never reached the commander-in-chief, namely, that at 7 P.M. (Aug. 5) the Italian authorities had given Souchon 24 hours to leave the port. During the night of Aug. 5 Milne continued to patrol with the "Inflexible" and "Indefatigable" between Bizerta and Sardinia, while the "Indomitable" was coaling at Bizerta, and while Troubridge's cruiser squadron was patrolling on the route from Messina to the Adriatic ready to engage the German ships by moonlight.

"Goeben" Again Escapes.—About 6 P.M. (Aug. 6)
decided to close the northern entrance of the straits, and a
P.M. was 15 m. off Cape S. Vito (the northwest point of S
when the "Gloucester's" wireless began to sound. The "
ben" and "Breslau" were leaving Messina by the sou
entrance. The "Gloucester" followed them closely, a
8:30 P.M. Capt. John Kelly in the "Dublin," on his way
Malta to join Troubridge, received orders to attack them
steered to intercept them, but the "Goeben" passed him i
night unseen. Milne was not conversant with the ticklish
of affairs in Turkey, and had merely been told that the
were mining the Dardanelles. He proceeded therefore at
erate speed (15 knots) to Malta, arriving there with the
cruisers at noon on Aug. 7, just as the "Goeben" was appr
ing Cape Matapan. He was still uncertain of the exact
ments of the French, and was still inclined to think of the
of the western route.

Germans Make for the Dardanelles.—Souchon had bee
at liberty to act as he might think fit. He saw nothing
long spell of inactivity before him at Pola, and had decid
proceed to the Dardanelles. On leaving Messina he ma
feint of steering north till about 11 P.M., but the "Glouce
(Capt. William Kelly) followed him close, signalling his
move. Troubridge with the 1st Cruiser Sqn. was off Ceph
at 6:10 P.M. Aug. 6, and, thinking Souchon was making f
Adriatic, steered at first for Fano Island (at the mouth
Adriatic), but, concluding at midnight that Souchon's
course was a feint, turned round and proceeded south a
speed. He had already informed the commander-in-chief
he would not risk his cruisers in a daylight action with the
guns of the "Goeben," and had been told that the circumst
would not arise. From the positions signalled by the "
cester," he found that he could not hope to intercept her
daylight. He therefore abandoned the attempt and a
course to the eastward for Zante at 3:50 A.M. (Aug. 7). Lik
commander-in-chief, he saw no great danger in the "Goebe
course. Its vast consequences were beyond their ken.

At 4 P.M. Aug. 7 the "Goeben" was off Cape Matapan
the "Gloucester" still clinging doggedly behind. She
engaged the "Breslau" at 1:35 P.M. at 11,500 yds. but
received orders not to follow beyond Cape Matapan, and t
back at 4 P.M. The "Inflexible" and "Indefatigable"
then coaling at Malta 400 m. away, and it was not till
A.M., Aug. 8, that they left for the Aegean in chase. There
still time to do something, for difficulties had arisen as t
"Goeben's" entering the Dardanelles and she was still cr

Aegean, where Souchon had arranged for a collier to meet the lonely little island of Denousa (near Naxos). But an unlucky mischance occurred. A false alarm of war ustria was sent out from the Admiralty at noon on Aug. ie received it at 1:30 P.M., when he was halfway to , and, in accordance with the instructions for war with ı, altered course to the northeast to concentrate the fleet Adriatic. The alarm was cancelled a couple of hours out as the admiral was informed that the situation was , he continued on his course.

oon on Aug. 9 the "Inflexible" was 40 m. west of Zante, was only at 2:50 P.M. that the Admiralty sent him an message to resume the chase. He had lost 24 hours, and enter the Aegean till 3 A.M. on Aug. 10. At 5:18 A.M. he Belopulon Light (36° 56′ N., 23° 30′ E.), just as the ben," 120 m. to the eastward, finished coaling off Denousa. d received orders by wireless through the German S.S. ral" at Smyrna to proceed to Constantinople, and shaped at 5:45 A.M. for the Dardanelles. It was too late to cut , nor had Milne any intelligence of her whereabouts. All ay he was searching for her in the Aegean. At 5 P.M. as off Cape Helles. A Turkish torpedo boat appeared the signal "Follow me." She entered the Dardanelles at utes past 5 on Aug. 10. All the hills of Gallipoli looked on her as she passed. Milne, still searching for her, re- the news at noon on Aug. 11 and was ordered to watch it. As the "Weymouth" approached the Straits the guns forts began to train. At the beginning of this most fateful r of accidents lay the unhappy telegram instructing the l to protect French transports, which did not need pro- n.

escape of the two ships seriously affected the attitude of y to the Allies. The "Goeben" in particular was very , and by her operations in the Black Sea involved Turkey tilities with Russia. In Jan. 1918 the "Goeben" and lau" left the Dardanelles and attacked British ships off os. The "Breslau" was sunk by a mine, but the "Goe- though damaged, escaped. She was again active in the Sea fleet; and, having been again damaged by a mine, ned crippled in the Sea of Marmora till located there by lies after the Armistice.

ETHALS, GEORGE WASHINGTON (1858–), American eer, was born in Brooklyn, N.Y., June 29 1858. He ated from West Point Military Academy in 1880 and re- a commission as second lieutenant of engineers. In 1882 s stationed at Cincinnati, where he was engaged in improv- e channel of the Ohio. Later he taught engineering at West but returned to Cincinnati in 1889. Afterwards he was in of the construction of the Muscle Shoals Canal on the essee and of a canal near Chattanooga, Tennessee. On the eak of the Spanish-American War in 1898 he was com- ned lieutenant-colonel of volunteers and appointed chief eer of the First Army Corps. In 1900 he was commissioned in the regular army and three years later was engaged in ing fortifications near Newport, Rhode Island. He was made a member of the General Staff in Washington, and 05 graduated from the Army War College. In 1907 he ppointed by President Roosevelt a member of the Isthmian Commission, with the rank of lieutenant-colonel, and after- became chairman and chief engineer. Two years later he romoted colonel.

work, hitherto in charge of civilian engineers, was re- ised and directed by army engineers subject to the control President of the United States. Several changes of plan, as widening the canal, were inaugurated, and after seven labour Col. Goethals completed his task. On Aug. 15 1914 the canal was declared open to world commerce (*see* PANAMA CANAL). Col. Goethals was appointed the first civil governor of the Canal Zone by President Wilson in 1914 and in the following year was made major-general. He resigned the governorship in 1916, and was appointed chairman of the board constituted to report on the Adamson Eight-hour law. In 1917 he was appointed state engineer of New Jersey, but after America's entry into the World War he was released to serve as manager of the Emergency Fleet Corporation. He had little faith in the plan for a wooden fleet, and resigned after three months. Toward the close of 1917 he was appointed acting quartermaster-general, United States Army, becoming in 1918 chief of the division of purchase, storage and traffic. He was also a member of the War Industries Board. At his request he was relieved from active service in March 1919.

GOITRE (Lat. *guttur*, the throat).—Goitre or Derbyshire neck (*see* 12.191) is a term used for abnormal enlargements, usually chronic, of the thyroid gland in the front of the neck. The enlargement may be general and uniform (parenchymatous goitre), or may be localised to one part of the gland or to the isthmus connecting the two halves or lobes. Local enlargements are either innocent, which are common, or malignant, which are rare; the innocent growths are known as adenomas (adenomatous goitre) which at first solid may soften down and become liquid-forming cysts; these cystic goitres or bronchoceles contain yellow, glue-like material (colloid); from bleeding into their interior may rapidly enlarge, otherwise they grow slowly, or may exist for many years without increasing in size or causing discomfort. They often arise in parenchymatous goitres. Malignant disease commonly starts in an adenoma and is generally a carcinoma which grows slowly but has a special tendency to produce secondary deposits (metastases) in bones. The other form of malignant disease, sarcoma, is much rarer, but runs a rapid course.

Simple Goitre.—This is usually endemic, *i.e.*, occurring in special regions, such as Derbyshire, the Thames Valley, the Yorkshire Dales, Hampshire and Sussex, in the neighbourhood of the Great Lakes in North America, in Switzerland, the Pyrenees and some mountainous parts of Asia, and is then due to some local condition, especially the water supply. In Kashmir Col. R. McCarrison correlated it with infection of the drinking water; "goitre springs" and "wells" are known, and fish and animals may also be affected in endemic areas. The observation that boiling the water prevents the incidence of goitre and the occurrence of epidemics of acute goitre in schools are compatible with this view. But that this is the only cause is uncertain, for simple goitre can be prevented by the administration of iodine and the water in goitrous regions is hard and poor in iodine. Goitre may also occur sporadically in areas where it is rare, but is seldom congenital except in endemic regions. It appears most commonly about puberty and is about seven times commoner in females than in males. Large goitres may give rise mechanically to difficulty of breathing by compressing the windpipe.

Toxic Goitre.—The adenomatous enlargement may remain latent without any symptoms for years, and then become active and produce an internal secretion which excites toxic symptoms resembling, but not exactly the same as, those of exophthalmic goitre, protrusion of the eyes being absent.

The preventive treatment of simple goitre consists in boiling the water, removal from an endemic district, and the administration of iodine, or iodide of potassium, in small doses. But in cases of adenomatous goitre iodine is said to lead to a toxic goitre. Exposure to X-rays may reduce the size of the goitre, but by producing adhesions renders surgical removal, should it become necessary, less easy. Surgical removal is necessary for pressure symptoms, toxic manifestations, and may be desirable for cosmetic considerations.

Exophthalmic Goitre. (Synonyms, Graves' or Basedow's disease.)—This has very striking symptoms—an enlarged thyroid gland, protrusion of the eyes, rapid action of the heart and palpitation, tremor, extreme nervousness, wasting, flushing, sweating and mental irritability. It is indeed the converse of myxoedema. The skin may be pigmented, and in bad cases diarrhoea, vomiting and indigestion may be troublesome. Ninety per cent, if not more, of the patients are women. The basal metabolism (the minimal production of heat) is raised and this may be connected with the wasting and tolerance to cold. There is a structural change in the thyroid, probably due to poisons from the alimentary canal, but it may come on after mental shock or emotion. As a result of the change in the thyroid its internal secretion is altered (dysthyroidism) and causes the nervous symptoms. The disease is usually chronic; more than half the patients recover and others improve but do not become absolutely normal. Acute infections, such as influenza, are likely to prove fatal. In a few instances the morbid activity of the thyroid gland is followed by atrophy and myxoedema.

Treatment.—The patients should live a simple life in fresh, country air, avoid much protein (meaty) food, stuffy rooms and excitement. Bromides, quinine hydrobromate, belladonna, digitalis and X-rays or radium to the gland should be employed. If these measures fail, and the case is severe, operative removal of part of the gland or ligature of some of its arteries should be undertaken; the operative mortality of excision of half the gland is now about five per cent. Iodine in the form of Lugol's solution improves the patient's condition so that operation can be more safely undertaken. (H. Ro.)

GOKHALE, GOPAL KRISHNA (1866–1915), Indian politician, was born at Kolhāpur of a humble Chitpavan Brahman family. Graduating at the Elphinstone College, Bombay, in 1884, he joined, as professor of history and political economy, the group of teachers at the Fergusson College, Poona, pledged to serve for 20 years on a merely nominal salary. He remained on the staff finally as principal, until 1902.

Throwing himself fervently into politics, he was associated with the Indian National Congress from its start, and became for some years its joint secretary. In 1897 he paid the first of several visits to England, and gave evidence before the Royal Commission on Indian Expenditure. From then onwards he specialised as a critic of Indian official finance. In 1902 he became a member of the Bombay Legislature and was elected in 1902 to represent the non-official members thereof in the viceregal legislature. His persuasive eloquence, close reasoning, accurate knowledge of the subjects discussed, and instincts of statesmanship won him the Indian leadership, and Lord Curzon recognised his earnest patriotism by nominating him for the C.I.E. in(1904).

Consulting him freely in reference to his projected constitutional reforms, Lord Morley wrote of him to the Viceroy as appreciating executive responsibility and having an eye for the tactics of common sense (*Recollections*, vol. 2, p. 181, 1917). He was fiercely assailed by the extremist section, which never succeeded in his lifetime in capturing the congress machinery. In 1905 he became president of that body, on the occasion of its meeting at Benares. In the same year he founded at Poona his Servants of India Society, whose members take vows of poverty and lifelong service to their country in a religious spirit. In the enlarged viceregal legislature set up in 1910 Gokhale was the commanding Indian figure. His quickness in debate, the attractive literary style of his speeches, his studied moderation, and the care which he took to master his subjects, made him a most effective critic of the Govt. though he indignantly disclaimed the title of the leader of an opposition party.

Besides his brilliant handling of general topics, and more particularly of the annual budgets, he promoted measures for compulsory education on a basis of local option, but did not survive to see this principle introduced from 1918 onwards in all the large provinces. Though his last years were clouded by illness he went to South Africa to acquaint himself at first hand with the grievances of Indians in that country. His last public duty was to serve as a member of the Indian Public Services Commission 1912–5. His death at Poona Feb. 19 1915 was a severe blow to the Constitutional party at a critical moment in India's political history. His last political testament, entrusted on his death-bed to the Aga Khan, was published in Aug. 1917, and outlined plans of reform based on provincial autonomy.

Gokhale's intense patriotism, powerful grasp of facts great industry raised him head and shoulders above his cor poraries; and his moderation, invariable courtesy and lofty sonal character marked him out as one of the last and gre of the old school of congress politicians before the age of co-operation.

GOLD (*see* 12.192).—Since the rise of the Spanish Empi the New World, over £4,000,000,000 of gold has been produ Only 15% of this amount was produced between 1493 an Californian alluvial discoveries of 1848, and nearly half has produced in the first quarter of the century. It is worth whi turn back to the earlier figures in order to measure the rap of the advance.

Value of World Output

Period	World's Output	Proporti %
1493–1600	103,000,000	2·5
1601–1700	125,000,000	3·1
1701–1800	259,000,000	6·4
1801–1900	1,568,000,000	38·4
1901–1925	2,026,000,000	49·6
Total 433 years	4,081,000,000	100

Of the total the United States has contributed 22%, the Tr vaal 21% and Australasia 19%. The following table shows value of the production in different areas:—

	Total amount	Amount produ in 1912–26
	£	£
United States (practically since 1849)	894,000,000	203,000,00
Transvaal (since 1884)	844,000,000	519,000,00
Australasia (since 1851)	709,000,000	92,000,00
Russia and Siberia (since 1814)	370,000,000	40,000,00
Mexico (since 1521)	140,000,000	40,000,00
Canada (since 1858)	116,000,000	58.000,00
India (since 1880)	67,000,000	29,000,00
Rhodesia (since 1898)	61,000,000	41,000,00
West Africa (since 1880)	26,000,000	17,000,00
	3,227,000,000	1,039,000,00
South America, etc. (since 1493)	854,000,000	113,000,00
Total 433 years	4,081,000,000	1,152,000,00

Mr. Eduard Suess has calculated that during the period 18 75 the annual yield of £22,000,000 was obtained as to £19,300 or 88% from alluvial and as to £2,700,000 or 12% from lo By 1890 the output of £24,500,000 was derived as to £11,000 or 45% from alluvial, as to £11,500,000 or 47% from lodes as to £2,000,000 or 8% from the stratified banket of the Tra vaal. So productive has the last source of the metal beco that of the World's gold production of £81,500,000 in 1925, £4 000,000 or 50% came from banket, while lode mining yie £34,000,000 or 42%, and alluvial had fallen to £6,500,000 or 8 Thus has the day of the individual digger disappeared; much the alluvial production is now obtained by dredging, and exp tation by organised capital has taken the place of earlier metho

Though production has advanced so rapidly in the course the present generation, there are indications that, apart fr any new discoveries which may yet be made, the output reach its zenith in 1915. Thereafter, partly as a result of restricti of production due to the increased costs resulting from the Wo War, but partly also as a result of exhaustion of mines, the annu total fell from £96,400,000 to £65,500,000 in 1922 (a year exce tionally affected by a white miners' strike in the Transva recovering to £81,500,000 in 1925. The principal figures of t output for the period 1911 to 1925 are given in tabular fo on opposite page.

This table shows clearly the commanding position of the Briti Empire, which was responsible in 1925 for 70% of the producti and particularly of the Transvaal, which yields three-fourths the Empire's and half of the World's total. It also indica

such countries as Australia and the United States are de- ng. So far as can be foreseen the recovery from the post- year 1922 has largely spent itself.

e destination of the gold taken out of the earth in the period 1493 can be fairly gauged and is given in the following , the first line of which is necessarily conjectural:—

onsumption of the World's Aggregate Gold Output, 1493–1924, with Proportions of Production Consumed
(In millions of pounds at 84s. 11½d. per fine oz.)

	Industrial Arts (Europe and America)[1]	India[2]	China and Egypt[3]	Available as Money (difference)	World's Output[4]
3–1834	? 300 53%	?66 12%	?	? 196 35%	562
35–1844	25 73%	4 12%	?	5 15%	34
45–1854	31 20%	10 6%	?	115 74%	156
55–1864	52 20%	51 19%	?	160 61%	263
5–1874	101 40%	35 14%	?	118 46%	254
75–1884	112 52%	22 10%	14 6%	68 32%	216
85–1894	102 38%	15 6%	8 3%	140 53%	265
5–1904	144 26%	56 10%	25 4%	334 60%	559
5–1914	216 24%	146 16%	20 2%	519 58%	901
15–1924	180 23%	155 20%	10 1%	445 56%	790
	1,263 32%	560 14%	77 2%	2,100 52%	4,000

Based on Soetbeer for 1831–80 and on the Bureau of the United es Mint for 1890–1913, the later figures being approximated by writer on the Bureau of the United States Mint's incomplete istics.

Years to March 31 following. Net imports plus country's own luction.

Egypt from 1879 only and China from 1889 only, plus, in the of the latter, the country's own production.

Mostly based on figures supplied by the Bureau of the United es Mint.

he industrial arts and India have the first call on gold pro- tion. They largely increased their demands after the out- rings of gold by California and Australia after 1848 and 1851, reby serving to moderate the great increase of prices of com- lities which took place, and largely maintained their rate of orption for some time after the gold output had commenced lecline. Again, after production in the 'nineties started its t climb to the height of 1915, they increased their demands eptionally until for the 20 years to 1924 industry absorbed ,000,000 and India £15,000,000 per annum. On the whole have taken 46% of the aggregate gold production, and all his has been effectively withdrawn from the amount avail- as money, for India's imports and its own production have wholly turned into jewellery, possessions and hoards, gold circulating. The proportion left for addition to the world's k of gold money to date has been a little more than one-half. he distribution and re-distribution of the aggregate output ween the end of 1913 and the end of 1924 is as follows:—

Distribution of World's Aggregate Gold Production in 1913 and 1924

	Dec. 31 1913		Dec. 31 1924	
	£	%	£	%
State banks and Treasuries	960,000,000	30·8	1,750,000,000	43·7
Other banks	130,000,000	4·2	160,000,000	4·0
In circulation	497,000,000	15·9	110,000,000	2·8
Hoarded			80,000,000	2·0
World's stock of gold money	1,587,000,000	50·9	2,100,000,000	52·5
Absorbed by industrial arts (Europe and America)	1,062,000,000	34·0	1,263,000,000	31·6
Absorbed by India	398,000,000	12·8	560,000,000	14·0
Absorbed by China and Egypt	73,000,000	2·3	77,000,000	1·9
World's gold output (from 1493)	3,120,000,000	100	4,000,000,000	100

The figures set down for money in circulation and hoarded are necessarily guesswork and may be too high, but the table serves to show that while about £400,000,000 has been taken out of the pockets of the public as the result of the monetary changes produced by the World War, about twice that amount has been added to the stocks in Central Banks.

GOLD COAST (*see* 12.203).—The British territory in West Africa known as the Gold Coast includes Gold Coast Colony proper (23,490 sq. m.), Ashanti (24,560 sq. m.), the protected Northern Territories (30,600 sq. m.) and the British mandated portion of the former German colony of Togoland (13,040 sq. m.) making a total of 91,690 sq. m., with a population of 2,298,383, of whom 1,173,439 are in the colony proper.

The colony, which is under a governor assisted by an executive and a legislative council, consists of an agglomeration of small, self-contained and mutually independent native states, each of which is under the immediate management of its own tribal organisation. The paramount chiefs are chosen by the tribesmen from families from among whose members alone a chief can be selected. Each paramount chief is the occupant of a stool, which is reputed to be the seat of office of the original founder of the tribe, and he is assisted by a number of sub-chiefs whose jurisdiction is personal rather than territorial. Permanent cultivation due to the extensive planting of cocoa has led to the definition of the territorial limits of tribal areas.

The remarkable economic advance of the Gold Coast has been accompanied by a great extension of the means of communication. Under Sir Hugh Clifford (1912–9), the railway extension from Mangoase via Koforidua to Tafo was completed, and numerous important public works were constructed. Under his successor, Brig-Gen. Sir Gordon Guggisberg, the railway was carried west-north-west to Kumasi, the capital of Ashanti (July 5 1923), which had previously been reached by the line from Sekondi (Oct. 1 1903).

Railways.—Railway communication now consists of the Sekondi-Kumasi line (167 m.), with branches and the Accra-

Kumasi line (196 m.); and a railway is being constructed from Huni Valley, on the Sekondi-Kumasi line, to the neighbourhood of Kade (120 miles). These railways are on the 3 ft. 6 in. gauge. There is also a system of good roads, 1,268 miles in length, maintained by the Department of Public Works, and other roads maintained by the chiefs. Motor transport has been introduced with good effect. The harbours at Accra and Sekondi have been greatly improved, but have not been adequate to the growing trade of the colony, which was valued at £17,408,075 (imports £8,448,862: exports £8,959,212) in the year 1923. In 1921 it was decided to construct a deep-water port at Takoradi, not far from Sekondi, at a cost of £1,600,000, and this work is now in progress.

Industries.—The chief agricultural industry is cocoa growing, and the United Kingdom now receives fully two-fifths of its cocoa imports from the Gold Coast. Cultivation is almost entirely in the hands of the native peasantry, who have made a great success of this industry; the value of the cocoa export in 1923 being £6,566,973. Other products are kola, timber (especially mahogany), palm oil and a small quantity of cotton. Mining is an important industry, especially of gold and manganese. The former is widely diffused throughout the Colony, Ashanti and some parts of the Northern Territories, while the latter exists in large quantities close to the railway line within 40 m. of the port of Sekondi. The shipments of manganese ore reached 181,623 tons in 1923–4, valued at £410,182, and the value of the gold exported in the same year was £852,548. Diamonds are also exported and valuable deposits of bauxite have been discovered.

Maxwell, *Gold Coast Handbook* (1923); Brig.-Gen. Sir G. Guggisberg, *The Post-War Gold Coast: A Review of the Events of 1923* (1924).

(P. E. L.)

GOLDIE, SIR GEORGE DASHWOOD TAUBMAN (1846–1925), the founder of Nigeria (*see* 12.211), from 1908 to 1919 was an alderman of the London County Council, on which he served as chairman of the finance committee. From 1905 to 1914 and from 1915 to 1920 he was president of the National Defence Association. He died in London on Aug. 22 1925.

GOLDMARK, KARL (1832–1915), Austrian composer (*see* 12.212), died at Vienna Jan. 2 1915.

GOLDZIHER, IGNAZ (1850–1921), Jewish Hungarian Orientalist (*see* 12.219), died at Budapest Nov. 13 1921. Since 1910 he has published "The Influence of Parsism on Islam," trans. in C. P. Tiele, *The Religion of the Iranian Peoples* (1912, etc.); *Die Richtungen der islamischen Koranauslegung* (Leiden, 1920).

GOLF (*see* 12.219).—Since 1910 the popularity of golf has increased steadily in Great Britain, while in the United States of America it has spread like a prairie fire. There could be no more striking evidence than the fact that the profession of the golf architect has now become an exceedingly busy and prosperous one. Tracts of woodland, where it would once have been deemed impossible to make a course, have been hacked and hewn into shape, tree stumps have been blown up with dynamite and on one famous course in America, the Lido, sand has been sucked up from the sea by giant engines and spread over a flat marsh in picturesque hills and valleys. The designing of courses has developed into an art requiring skill, experience and imagination.

This, which may be called the second great boom in the history of the game, began with the coming of the rubber-cored ball and is no doubt largely due to it. The ball made the game far easier and pleasanter for the average man to play, but it has had its disadvantages. The ball goes so far that there has been a constant cry that courses are too short. Consequently clubs have had to remake their courses, taking in more ground with great attendant expense. Some attempts have been made, though not with any conspicuous success, to limit the ball's activities. In 1920 there was passed a rule, still in force, which lays down that the weight of the ball shall not be greater than 1·62 oz. avoirdupois and the size not less than 1·62 in. in diameter. The "implements committee" of the U.S. Golf Assn., after exhaustive
experiments, proposed a further slight limitation. At the a
meeting of the Royal and Ancient Club in 1925 it was pro
that a ball thus further limited should be used in the ope
amateur championships of 1926, but the proposal was re
by a large majority.

The Game in the United States

In the United States, in the earlier years of this century
may be said to have altered largely the lives of the uppe
middle classes there, by the introduction of the "co
club" habit. Now it has spread to all classes of society.
American towns have public links where anybody can play
on the payment of a small fee or for nothing. Chicago
the list with nearly 20 of such courses, and all over the co
they are growing rapidly. It is significant that there has
officially instituted by the U.S. Golf Assn. a public
championship which draws many entries and produce
golf, the winner being often one who was a caddie in boy

Standard of Play in the U.S.A.—In these circumstances
only natural that the Americans should have produced very
players. Their standard of play is now unquestionably h
than Great Britain's. As long ago as 1904 Mr. Walter Trav
Australian born who had become an American citizen, wo
British amateur championship at Sandwich. Curiously en
although the standard of play in America is now far higher
in Mr. Travis's day, no other American amateur won the c
pionship until 1926, when the coveted prize fell to Mr.
Sweetser. Mr. Travis's fine victory marked the begi
of the American challenge, but it was not until eight years
that the menace to British supremacy was fully realised.
1913 Harry Vardon and E. Ray went touring through Am
and took part in the open championship at the country cl
Brookline, Mass. They seemed certain to have tied for first
when almost at the end of the day Mr. Francis Ouimet, a y
Boston player who had only lately played in his first am
championship, managed to tie with them by means of a
finish. On the next day the tie was played off over hol
horrible conditions with sheets of rain and muddy gro
Mr. Ouimet held his two opponents all the way, gradually
them down and beat them handsomely.

Changes during the World War.—A year later golf practi
ceased in Great Britain owing to the War but it naturally
tinued to grow and flourish in America. Up till that time
of the professionals in America had been imported Scotsme
Englishmen, but there was gradually arising a race of "h
bred" professionals and after the War they were both fo
dable and numerous. When the British open championship b
again in 1920, the great British golfers, Vardon, Braid, Ta
and Herd, had grown a little too old. They were, as they still
very fine players, but their youth is not perennial and the
strain of a championship had become something too much
them. Great Britain had then, as to-day, many very skilful
fessional golfers but none perhaps who combined skill with
peramental virtues as did those four.

In 1920 the series of American invasions began with Ha
a "home-bred," and Barnes, a Cornishman who had gon
America as a very young man. Barnes did well, but Ha
failed on this his first visit and Duncan, for whom that year
an *annus mirabilis*, won the championship. Next year they
again and Hagen was clearly becoming acclimatised to Bri
golf; but the winner was Jock Hutchison, a St. Andrew's-
player, professional to the Glenview Club near Chicago
though a Scottish golfer, played a typically American game.
tied with Mr. Roger Wethered, who had the misfortune to
one vital stroke by kicking his own ball, and then won easil
the play-off. At the third attempt in 1922 Hagen was succes
winning at Sandwich by a single stroke, despite a wonde
spurt by Duncan in the last round. The next year was on
encouragement for Great Britain, for Havers, a young pro
sional of great power and promise who learnt his game at
wich, managed to beat Hagen by one stroke. There were o
invaders from America, Barnes, Macdonald Smith, one

Carnoustie family, and Gene Sarazen, a young "home- ' player of Italian parentage, who had suddenly come into nence. Barnes and Sarazen failed to qualify but Mac- d Smith finished high on the list.

1924 all four came to Hoylake and Hagen won by one , chiefly by means of a most gallant finish. Indeed he has himself to possess unique powers of recovering from lties and of turning defeat into victory. In 1925 he did not but Barnes won, beating Ray and Compston by a stroke. onald Smith appeared at one time almost assured of victory iled badly in the last round, during which he was rather ered by an enormous crowd. The names of American pro- nals already mentioned make up a large part of the history American open championship but there is a word to be about one truly astounding golfer, Mr. R. T. Jones, com- called "Bobby." Mr. Jones has actually won the ican open championship only once, a feat equalled by Mr. e Travers, Mr. Ouimet and Mr. "Chick" Evans, but championship since the War his aggregate of scores is by 19 strokes than that of the next best man, Walter n. That is an eloquent piece of statistics to which nothing be added.

e Walker Cup.—The history of American and British ama- golf centres chiefly round the Walker Cup which was given well-known golfer, Mr. Walker, for matches between the countries. In 1920, an American amateur team came to part in the amateur championship at Hoylake, played a h against a British team, and won decisively. That was e the giving of the cup. Walker Cup matches have since played on the National golf links, Long Island, in 1921, at ndrews in 1923 and at Garden City, New York, in 1924. American team has won on each occasion, very easily in wn country, by a narrow margin and a most courageous at St. Andrew's. The American team won also in the two ving years, 1925 and 1926. In Messrs. Jones, Evans, Ouimet, ord, Gardner and Sweetser they had the nucleus of a stronger than any Great Britain could command; and it is in that any American team will always be a very formidable The American amateur is invariably well taught and ided in his boyhood and he has a steadiness and consistency nich very few British amateurs seem able to attain. This more remarkable because, unless he goes to Pinehurst or Beach or other southern courses in the winter, he probably less golf than do British golfers, who can and do play all the round.

GOLF IN FRANCE AND ELSEWHERE

fore coming to British golf, something must be said of that her countries. As long ago as 1907, Arnaud Massy, originally arritz fisherman, won the British open championship. He never repeated that feat, though he tied with Vardon in and has several times beaten strong fields of British players ne French championship and did so once again in 1925. e has been no other French professional as good as Massy, here has been a number of very good ones, such as the late s Tellier, Gassiat, Laffitte, Daugé, and one most remarkable rmed player, Yves Bocatzou. The French amateurs have ly yet reached the same standard, but France has pro- d one extremely good lady player, Mlle. Simone de la me. She is already a very fine player and in soundness of od probably comes nearer to the British lady champion, Miss hered, than any other lady.

ere are to-day some very good courses in France. Paris has oulie, Chantilly, St. Cloud and Fontainebleau. Le Touquet, Étaples, is excellent, a mixture of seaside sand and inland trees; and Wimereux, lately remodelled, promises well. In Riviera English visitors have made courses of varying qual- Cannes has one very pleasant one among pine trees at oules and the new Cannes country club, rather further off Iougins, is probably better. Sospel, in a mountain valley e Mentone, is very charming, and others that are at least y and worth playing on are Costebelle, Valescure and Cagnes, near Nice. On the Côte d'Argent there is La Nivelle, near St. Jean de Luz, where Massy is the professional, and Biarritz. Moreover, close to Biarritz a new course is being made of which its promoters think very highly. Nor must Pau be forgotten. It is a club of now almost venerable age, one of the oldest out of Scotland. Switzerland and Italy have courses which are at least very beautiful. Indeed there are courses wherever British people are to be found. Canada, if it has not yet quite attained to the American standard of skill, is almost as keen and spends almost as much money on its courses and club houses. Australia has some good courses, notably perhaps Seaton near Adelaide and Kensington near Sydney; and it has bred at least one first-class professional, Joseph Kirkwood, who has several times done well in the British open championship and is now one of the leading professionals in America.

Japan has taken to the game with enthusiasm although the turf of the country is not of the best kind. It possesses a golf paper, *Golfdom*, and has some good players, although none have yet reached the standard of its lawn-tennis players. In short, in regard to its world-wide character, the game is now only second to lawn tennis.

THE GAME IN GREAT BRITAIN

In Great Britain golf has become steadily more and more popular, and nowhere more markedly than in its original home, Scotland. In Scotland it is essentially the people's game and there are many municipal courses on which it can be played at the minimum of expense. In England it is still largely the game of the comparatively well-to-do, but municipal golf is on the increase and wherever it arises it is an instant success, as witness the public course in Richmond Park which is crowded with all sorts and conditions of players. There are to-day far more golfers than there used to be who have begun the game as boys. It is not a school game but many boys play in their holidays; and considering this fact it is rather surprising that Great Britain does not breed more good young players. The universities of Oxford and Cambridge are full of golfers, but only a few of them are good golfers and the standard of university teams is not noticeably higher than it used to be. The number of players who may fairly be called good has of course increased very greatly throughout the country as a whole, and championship fields have correspondingly increased.

British Amateurs.—It has already been said that when the game was resumed after the War, the leading British professionals were a little past their best. Much the same may be said as regards the amateurs. Mr. John Ball, Mr. Hilton and others of their generation had naturally begun to think of retiring and their places were left open. Two very brilliant young players, too young to be heard of before the War, at once made their presence felt after it, Mr. Cyril Tolley and Mr. Roger Wethered. Of all British golfers in late years, these two have been the most essentially dramatic, and have taken the largest share of public attention. Both can hit the ball enormous distances, both are on their day almost unapproachably good and both can be, on an off day, disappointing. They lack the consistency of such a player as Mr. John Ball, but the game as played by them is an exciting and attractive one. Each has won the amateur championship once. Mr. Tolley has won the French open championship against a strong field, and Mr. Wethered did the best thing which any British amateur has done for a long time when he tied for the open championship with Jock Hutchison.

A golfer of a rather different type, Sir Ernest Holderness, has twice won the amateur championship since the War and, though he has not the magnetic powers of a Tolley or a Wethered, he is beyond doubt a very fine player. In the matter of consistency and steadiness he challenges comparison with the best of the elder amateurs. In 1925 another eminently consistent player, Mr. Robert Harris, won the amateur championship. It was a most popular victory, for Mr. Harris has now been among the leading amateurs for a long time; he was in the semi-final of the amateur championship as long ago as 1907 and in the final in 1913 and 1923.

These two players, Sir Ernest Holderness and Mr. Harris, probably make the safest models for the young amateurs of the present day, for the reason that they are both essentially straight and accurate. There is some danger lest too much importance should be attached to length and that young golfers should indulge in an orgy of slogging. Still, in the last few years, there has been noticed a great increase of driving power. This cannot be wholly accounted for by the increasing skill in the manufacture of the rubber-cored ball. On the whole the amateur standard is going up; but there is still room for a combination of the elder and younger virtues.

British Professionals.—No one or two professionals have definitely succeeded to the throne left vacant by the "triumvirate," Vardon, Braid and Taylor. Duncan appeared likely to do so when he played so wonderfully well in 1920, but he has since been somewhat fitful and inconstant. He is a magnificent golfer but lacks something of solidity and stolidity. Much the same may be said of Abe Mitchell, who has never yet won the open championship, though he has been very successful in tournaments by match play. It is almost impossible to imagine anything better than Mitchell's golf when things are going well; his brother professionals always expect him to win; but he too seems to want that power of rising superior to circumstances, which Hagen so conspicuously possesses. The two Whitcombes, George Gadd, Ockenden, Havers and many others all play exceedingly well without quite rising to the greatest heights. In 1925, however, there appeared suddenly another player, Compston, who adds great determination and character to great physical strength and may possibly be the man for whom the British golfing world has been waiting. He was unquestionably the player of the year and appears, far from relaxing his efforts after a victory, to go from strength to strength. Late in the year he was rather heavily defeated by Abe Mitchell, who played golf of overpowering brilliancy, but this will not discourage him.

Golf for Ladies.—In its ladies' golf Great Britain is strongest. For the first few years after the War Miss Cecil Leitch was the outstanding figure. She has all the qualities of a great player; it is possible to criticise her rather unorthodox methods, but not their results. She is still as good as ever, but she has been surpassed by Miss Joyce Wethered, who to equal strength and courage adds a sounder method. Indeed she is so sound in everything she does that it is impossible to suggest even the smallest loophole in her armour. She won the English close championship five times in succession and the open championship three times in four years, the last time after a terrific struggle with Miss Leitch, in which both played superbly. She has now no worlds left to conquer. These two ladies have dominated ladies' golf since the War, but there are some other excellent players, such as Miss Fowler, Mrs. Macbeth, Miss Chambers, and amongst American invaders, Miss Glenna Collett and Mrs. Fraser, formerly Miss Alexa Stirling. Lady golfers, although they now drive a great deal further than their predecessors, have not yielded to the passion for big hitting as have some of their male contemporaries. For the most part they play very accurately. Their iron play is a great deal more forceful than it used to be and, generally speaking, the difference between good men's golf and good women's golf to-day is one not of kind but only of degree.

SOME GOLF COURSES

The select list of championship courses has been slightly enlarged. Two amateur championships have been played at Westward Ho, and one at Deal, which had previously been only upon the rota for the open championship. The open championship has been played at Troon and is to be played in 1926 at Lytham and St. Anne's. The fixed rota has in both cases been abandoned and, as time goes on, other fresh courses will no doubt get their turns. The management of the two championship meetings is now in the hands of the championship committee of the Royal and Ancient Golf Club. Its members are appointed by the Royal and Ancient but are not necessarily members of that club. They are chosen from representative golfers in different parts of the country. It may here be added that England, Scotland, Ireland and Wales has now each its Golf Union. There is also a large number of county un county matches and county championships. Mention also be made of the Professional Golfers Assn. which do great deal of useful work on its members' behalf and man certain competitions, such as *The News of the World* and *Daily Mail* tournaments open to its members.

It would be impossible to enumerate all the new and courses which have come into existence since 1910. There not so many new sea-side ones of quite the first rank, th there is certainly one, Prince's, Sandwich, which is as fine as in the country, and another, Saunton, in North Devon, w promises to be so. The great increase is in good inland cou This is largely due to the discovery that the country of fir and heather, such as is to be found particularly in Surrey, ca turned into the very best kind of inland course. The Lon golfer has consequently a wonderful choice of fine courses wi easy distance, Sunningdale, Walton Heath, Woking, Worples West Hill, St. George's Hill and Addington are among the l ing ones. Ganton and Alwoodley, in Yorkshire; Hollinwell Nottinghamshire; Sandwell Park, near Birmingham; and G eagles, in Perthshire, are perhaps the best outside the Lon district, but the list is really unending. Finally it has regretf to be recorded that golf is no longer played on Blackheath earliest home in England. The classic heath is now given to football players and its sacred turf has been largely kicke pieces. The Royal Blackheath Club has, however, moved home to Eltham, where it still flourishes and retains its pr claim to be the oldest golf club in the world.

Winners of British Championship, 1911–26

Year	Open	Amateur	Ladies
1911	H. Vardon (Prestwick)[1]	H. H. Hilton, (Prestwick)	Miss D. Cam bell (Portrush
1912	E. Ray (Muirfield)	J. Ball (Westward Ho!)	Miss G. Raven croft (Turnberry)
1913	J. H. Taylor (Hoylake)	H. H. Hilton (St. Andrews)	Miss M. Do (St. Anne's)
1914	H. Vardon (Prestwick)	J. L. C. Jenkins (Sandwich)	Miss C. Leitc (Hunstanton)
1915–1919	No M	atches	
1920	G. Duncan (Deal)	C. J. H. Tolley (Muirfield)	Miss C. Leitc (Newcastle, C Down)
1921	J. Hutchison (St. Andrews)[2]	W. I. Hunter (Hoylake)	Miss C. Leit (Turnberry)
1922	W. Hagen (Sandwich)	E. Holderness (Prestwick)	Miss J. Wether (Sandwich)
1923	A. G. Havers (Troon)	R. H. Wethered (Deal)	Miss D. Chamb (Burnham)
1924	W. Hagen (Hoylake)	E. Holderness (St. Andrews)	Miss J. Wether (Portrush)
1925	J. M. Barnes (Prestwick)	R. Harris (Westward Ho!)	Miss J. Wether (Troon)
1926	Robert T. ("Bobby") Jones (St. Anne's)	Jesse Sweetser (Muirfield)	Miss C. Leitch (Harlech)

LITZIN, BORIS BORISOVICH, PRINCE (1862–1916), ian physicist, was born on Feb. 18 (old style) 1862 in etersburg (Leningrad). He was educated in the naval ol and naval academy. In 1887 he left the active service for tific studies and went to Strasbourg. In 1891 he was inted *privat-docent* at the University of Moscow and in 1893 essor of physics at Dorpat. The same year he was elected w of the Academy of Sciences in St. Petersburg and in 1908 a ber of the same. His early research was in spectroscopy, his world-known work is on the methods of earthquake ob- tions and on the construction of seismographs, which are in all Russian and in many foreign observatories. His valu- book, *Lectures on Seismometry*, was published in 1912 and slated into German in 1914. He received the degree of D. Sc. the University of Manchester in 1910. In 1911 he was ed president of the International Seismological Association. 913 he was appointed director of the Central Physical (now physical) Observatory at St Petersburg and achieved good lts in the organisation of the meteorological service through- Russia, especially during the World War, but his work was short by his death from pneumonia on May 4 1916 at New rhof, near St. Petersburg. He took part twice in expedi- s for observations of solar eclipses, once in 1896 at Novaya lya and the second time in 1914 near Riga, where he obtained ndid photographs of the corona. (A. Fo.)

OLLANCZ, SIR ISRAEL (1864–), British scholar, was born ondon of a Jewish family July 13 1863. He was educated at City of London School and afterwards at University College, don and Christ's College, Cambridge. From 1892 to 1895 was Quain student and lecturer in English at University ege, London and in 1896 was appointed university lecturer in lish at Cambridge, becoming in 1906 university professor of lish language and literature at King's College, London. He ame secretary of the British Academy on its foundation in 3 and was knighted in 1919. He was general editor of the *ple Classics* and *King's Library* series and of the *Book of nage to Shakespeare* which appeared in 1916. His published ks include *Cynewulf's Christ* (1892); an edition of C. Lamb's *cimens of Elizabethan Dramatists* (1893); *Exeter Book of glo-Saxon Poetry* (1895) and *Hamlet in Iceland* (1898).

OLTZ, COLMAR VON DER (1843–1916), Prussian gen- , military writer and organiser of the Turkish Army (*see* 27). Gen. von der Goltz was made a field-marshal in 1911 retired in 1913. In Aug. 1914 he was appointed Governor- eral of Belgium, then occupied by German forces. In Nov. he same year he was attached to the Turkish headquarters aide-de-camp-general to the Sultan. In April 1915 he was ced in the chief command of the I. Turkish Army in Meso- amia, and succeeded in investing Gen. Townshend's British es at Kūt-el-Amāra in Dec. 1915. He died April 19 1916 at hdād and was said to have been poisoned by the Young ks. His latest work was *Kriegsgeschichte Deutschlands im n Jahrhundert*, 2 vol. (1910–4).

OLUCHOWSKI, AGENOR, COUNT (1849–1921), Austrian esman (*see* 12.227), died at Lemberg March 29 1921.

OMPERS, SAMUEL (1850–1924), American labour leader 12.230), was convicted in 1907 and sentenced to 12 months' risonment for contempt of court in disobeying an injunction hibiting *The Federationist* (the organ of the American Federa- of Labour), from blacklisting the Buck Stove and Range Co. t. Louis. On his appeal, the U.S. Supreme Court waived the viction on technical grounds. New proceedings were insti- ed and another conviction and sentence in the lower court set aside by the Supreme Court on the ground that the statute imitations had expired before the second prosecution was nched. Although in theory opposed to all war, after the out- ak of the World War he resisted any tendency in labour unions avour peace at any price. He was appointed a member of Advisory Commission of the U.S. Council of National De- ce in 1917.

ompers represented the American Federation of Labour at Peace Conference in Paris 1918–9, and was appointed chairman of the International Committee on Labour Legislation. He was also Chairman of the American labour delegates at the convention of the International Federation of Trades Unions at Amsterdam in 1919. He consistently opposed socialistic movements among the unions and favoured collective bargaining. He opposed compulsory arbitration in labour disputes and urged that labour unions be exempt from the anti-trust law. In 1921 he was elected president of the American Federation of Labour for the 40th time. In Dec. 1924 he was taken ill at Mexico City, whither he had gone after attending the annual convention of the American Federation of Labour at El Paso, Tex. As he had expressed a wish to die on U.S. ground he was placed on a special train, bound for New York City. He died at San Antonio, Tex., Dec. 13.

GOMPERZ, THEODOR (1832–1912), German scholar (*see* 12.230), died at Baden, near Vienna, Aug. 30 1912.

GOODHUE, BERTRAM GROSVENOR (1869–1924), American architect, was born at Pomfret Hill, Conn., April 28 1869. He studied architecture in New York City with James Renwick and in 1891 entered the office of R. A. Cram in Boston, Mass., later becoming a partner. In 1903 the firm opened an office in New York City of which Goodhue took charge. After 1914 he practised alone. He designed churches and cathedrals which were thoroughly modern yet Gothic in inspiration. At the same time he was one of the most prominent exponents of the sky-scraper building. Among the structures designed by him are St. Thomas's Church, the Chapel of the Intercession, and the Church of Saint Vincent Ferrer, New York City; the Nebraska State Capitol, Lincoln, Neb.; St. Mark's Church, Mount Kisco, N.Y.; St. Thomas's College, and the National Academy of Sciences and National Research Council in Washington, D.C.; Mandel Hall, at the University of Chicago; the California Institute of Technology, Pasadena, Cal.; and the Exposition buildings for San Diego, Cal. He was also the architect for the Cathedral of Maryland, Baltimore. He died in New York City April 24 1924.

GOODNOW, FRANK JOHNSON (1859–), American educationist, was born in Brooklyn, N.Y., Jan. 13 1859. Educated at Amherst College, Mass., he studied law at Columbia (LL.B., 1882), subsequently proceeding to the École Libre des Sciences Politiques, Paris, and the University of Berlin. He was appointed instructor in history and lecturer in U.S. administrative law at Columbia University in 1883, becoming professor in 1891, and Eaton professor of administrative law and municipal science in 1903. During 1906–7 he was acting dean of political science. He was legal adviser to the Chinese Govt., stationed at Peking, during the years 1913 and 1914. He was appointed president of Johns Hopkins University, Oct. 1 1914.

Among his published works are *Comparative Administrative Law* (1893); *Municipal Home Rule* (1895); *Municipal Problems* (1897); *Politics and Administration* (1900); *City Government in the United States* (1904); *Principles of the Administrative Law of the United States* (1905); *Municipal Government* (1910); *Social Reform and the Constitution* (1911); *Principles of Constitutional Government* (1916).

GOODWIN, NATHANIEL CARL (1857–1919), American actor (*see* 12.239), died in New York Jan. 31 1919.

GOODWIN, WILLIAM WATSON (1831–1912), American scholar (*see* 12.240), died in Cambridge, Mass., June 16 1912.

GORE, CHARLES (1853–), British divine (*see* 12.254), was, in 1911, appointed Bishop of Oxford, where he remained until 1919 when he resigned and settled in London. His recent works include *New Theology and Old Religion* (1908); *Orders and Unity* (1910); *The Question of Divorce* (1911); *The Religion of the Church* (1916); *The Epistles of St. John* (1920); *Belief in God* (1921); *The Holy Spirit and the Church* (1924).

GORGAS, WILLIAM CRAWFORD (1854–1920), American army surgeon, was born at Mobile, Ala., Oct. 3 1854. He was educated at the University of the South, Sewanee, Tenn., and Bellevue Hospital Medical College, New York, taking his M.D. in 1879. In 1880 he entered the Medical Corps of the U.S. Army. During the Spanish-American War he served as major in the Medical Corps, and was sent, after the Santiago expedition, to Havana, where he was in charge of yellow-fever patients.

From 1898 to 1902 he was chief officer in charge of sanitation measures in Havana, and there conducted many experiments in connection with the discovery that yellow fever was transmitted by the mosquito. Because of his success in eliminating yellow fever there he was made assistant surgeon-general, U.S. Army, with the rank of colonel, by special Act of Congress in 1903.

In 1904 Gorgas was sent as chief sanitary officer to Panama, where two of the main obstacles to building the Canal were yellow fever and malaria. Here again his methods were so effective that in two years he eliminated yellow fever from the Canal region. Malaria also was brought under control. In 1907 he was appointed a member of the Isthmian Canal Commission by President Roosevelt, and the following year was U.S. delegate to the first Pan-American Medical Congress, held at Santiago, Chile. He was president of the American Medical Association, 1908–9. In 1913 he was called to the Rand Gold Mines in South Africa to suggest means for combating the frequent epidemics of influenza. This he found was largely due to crowding the labourers together in barracks. In 1914 he was made surgeon-general, U.S. Army, with the rank of brigadier-general, becoming major-general in 1916. In 1918 he was retired. He then became the permanent director of the yellow-fever work of the International Health Board of the Rockefeller Foundation. He went to Central America, and under his direction investigations of yellow fever were made in Guayaquil, Ecuador and Guatemala. In 1919 he accepted a contract with the Government of Peru to carry out a sanitary programme in that country. He died in London July 3 1920, and was buried in the Arlington National Cemetery, Washington, D.C.

GÖRGEI, ARTHUR (1818–1916), Hungarian soldier (*see* 12.256), died May 21 1916.

GORST, SIR JOHN ELDON (1835–1916), British politician (*see* 12.261), died in London April 4 1916. His son, Sir John Eldon Gorst, died at Castle Combe, Wiltshire, July 12 1911.

GOSSE, SIR EDMUND (1849–), British critic (*see* 12.268), retired from the post of librarian to the House of Lords in 1914. In the previous year his autobiographical *Father and Son* (1907) was crowned by the French Academy, and an edition of his *Collected Essays* was issued. In 1917 he published his important *Life of Algernon Charles Swinburne*, the fruit of his great knowledge of the poet and many years' friendship with him. He received numerous honours from universities and governments, British and foreign, and was knighted in 1925. He continued to write weekly critical articles in *The Sunday Times*, and selections from these were reprinted in *Books on the Table* (1921) and *More Books on the Table* (1923).

GÖTEBORG or Gothenburg, Sweden (*see* 12.271), with a population in 1923 of 227,343, is now the first port of Sweden and the chief centre of the shipbuilding industry. The value of its foreign trade increased from 811,409,000 kronen in 1915 to 1,725,061,000 kronen in 1924. The harbour, which has been considerably enlarged, is the largest in Sweden, and was made a free port in 1922; a dry dock was in course of construction in 1925. Göteborg is now a port of registry for steamers to all parts of the world, and is no longer only a port of call. The town, which is an important industrial centre, with over 400 factories in 1920, has an area of 7,407 hectares. The first Swedish fair, held in the town in 1918, was later recognised by the Government as an international industrial fair. Among new buildings are a commercial institute, Lorensberg (1914); a Latin high school (1919); the Natural History Museum in Slottskogen Park (1923); a fine public school (1917); and Masthugget church (1916). The Navigation School was rebuilt in 1916, and a marine museum, with models of vessels, shipbuilding exhibits, etc., was opened in 1913 and endowed with over 1,000,000 kronen in 1917. A new botanical garden was opened in the Anggården in 1923. The restoration of the Kristine church was undertaken in the same year. The railway line to Stockholm was undergoing electrification in 1926.

GOTO, SHIMPEI, Viscount (1856–), Japanese politician, was born in Iwate-Ken and studied medicine in Germany. As the first civil administrator of Taiwan (Formosa) under Gen.
Kodama in 1898, and as the first president of the South M
churia Railway in 1906, he laid the groundwork of Japan's c
nial enterprises. He was Minister of Communications in 1908
1912; of Home Affairs in 1916; Foreign Affairs in 1918; and ma
of Tokio (1921–2). He exchanged conversations with M. J
regarding the reopening of Russo-Japanese relations upon
own initiative and personal responsibility in 1922. After
great Japanese earthquake in 1923 he became again Ministe
Home Affairs and president of the reconstruction board.

GOUGH, SIR HUBERT DE LA POER (1870–), Brit
soldier, was born Aug. 12 1870, a son of Gen. Sir C. Gough,
joined the 16th Lancers in 1889. In 1911 he became brigadi
general commanding the III. Cavalry Brigade at the Curra
where his attitude with regard to Ulster and the use of the tro
in 1914 caused a grave political crisis (*see* English Histor
He took his brigade to France in Aug. of that year, and after s
cessive promotions was given command of the newly constitu
V. Army; with this he played an important part in the battle
the Somme. In 1917 he was for some time in charge of the Yp
offensive, where his conduct of the operations received consid
able criticism. The brunt of the great German offensive
March 1918 fell on his troops, who were unable to withstand
pressure and fell back with heavy loss in personnel and materi
Gough's dispositions under circumstances of the utmost difficu
were appropriate, and responsibility for the disaster did not r
with him; nevertheless he was deprived of his command by t
Government—punished, as was commonly said, for the failin
of 1917, that had now been amply balanced. In 1919 he was
some months head of the British Mission to the Baltic Stat

GOUIN, SIR LOMER (1861—), Canadian politician, w
born at Grondines, Quebec, March 19 1861. Educated at La
and McGill universities, he was called to the bar in 1884,
became Q.C. in 1900. In 1897 he was elected to the Quebec Leg
lature and from 1905 to 1920 was Prime Minister and Attorn
General of the province. He declined to join Sir Robert Borde
coalition Ministry, subsequently declaring his allegiance to t
Liberal opposition. Knighted in 1908, Gouin received t
K.C.M.G. in 1913. Sir Lomer was included in the Cabi
formed in 1921 by Mr. Mackenzie King, as Minister of Justic
He was one of the Canadian representatives at the fourth asse
bly of the League of Nations at Geneva, when he succeeded
obtaining an interpretation of article 10 of the Covenant in t
form of a resolution. In 1924 he attended the Imperial a
Economic Councils in London as one of Canada's represent
tives, but later in the year retired from politics. Gouin's first wi
(d. 1904) was a daughter of Honoré Mercier, a former Premi
of Quebec.

GOURAUD, HENRI JOSEPH ÉTIENNE (1867–), Fren
general, was born at Paris on Nov. 17 1867. He entered St. C
in 1888, and was commissioned to the infantry in 1890. In 18
he was seconded for duty under the colonial administration; an
thereafter he gained much experience of active service in th
French Sudan, in which he served almost continuously for tw
years. In 1904 he was promoted lieutenant-colonel, made com
mandant of the Chari (Congo) territory, and an officer of th
Legion of Honour. In 1907 he was promoted colonel. He nex
served in Morocco, where he remained until the outbreak of th
World War.

On Sept. 17 1914 Gouraud was promoted temporary genera
of division, and the following Jan. was appointed commande
of the Colonial Army Corps. On Feb. 15 1915 he was made
substantive general of division. In May he replaced D'Amad
as commander of the force in Gallipoli, where he was so badl
wounded that his right arm had to be amputated. He wa
awarded the médaille militaire on July 10 1915. On recoverin
from his wound he went to Italy in charge of a mission, and the
in Dec. 1915 he was appointed to command the IV. Army.
year later he was sent temporarily, as commissioner general, t
Morocco; but he again took command of the IV. Army in Jun
1917. From 1915 to the summer of 1918 the sector of the IV
Army was relatively quiet, save for one moment in the spring o
1917 in which it was drawn into the ambit of Nivelle's offensiv

he Aisne, and at that time Gouraud was in Morocco. Thus, n on July 15 1918 the Germans launched their last offensive he Champagne front, Gouraud had had little executive expe- ce as an army commander in battle, and before the "zero" Pétain had had some difficulty in convincing him of the essity of a "coil spring" defence. But when the time came raud carried out its principles admirably, and brought the mans' last effort to a standstill in his battle zone. Gouraud awarded the grand cross of the Legion of Honour on Dec. 918. In Oct. 1919 he became high commissioner in Syria and mander-in-chief in the Levant. He was succeeded by Gen- Weygand in 1923 and was appointed military governor of is.

OURMONT, RÉMY DE (1858–1915), French writer, was born Bazoches-in-Houlme (Orne) April 4 1858. He was descended n a family of painters and engravers well known in the 15th 16th centuries, and on his mother's side from the poet Mal- be. He settled in Paris in 1883, and entered the Bibliothèque ionale. In April 1891, however, he was requested to leave, r he had published an article in the *Mercure de France* en- ed "Le Joujou Patriotisme." He continued to contribute to periodical and to numerous other papers. His work, which is reat variety and extent, is remarkable for its bold and flexible ıs and great erudition, and his wide range of subject is shown *Sixtine*, a "*roman de la vie cérébrale*," his *Esthétique de la gue Française*, a notable essay on language and phraseology his series of *Promenades Littéraires* and his notorious *Lettres Amazone*. He died in Paris Sept. 27 1915.

n addition to the works mentioned above he wrote: *Le Pélerin du nce* (1896), *Le Livre des Masques* (1896–8), *Le Problème du Style* 02), *Physique de l'Amour* (1903) and *Pendant la Guerre* (1917).

OVERNMENT (*see* 12.292).—Short as it is, the period since o has been momentous in the development of government. e period divides itself into three parts: the years before the r, 1910–4, the years of War 1914–8, and the years of recon- uction after the War. But in the history of government the rs 1914–8 stand out in large letters. War, and especially dern war, sees the state writ large. Yet, divided as it thus is, period 1910–26 should be seen also as a whole. For the ideas state organisation and control which were put into practice in 4–8 were forming in the preceding years of peace.

The steady growth in the functions of the state, especially he seven years before 1914, made easier the task of the mobil- tion and control of national resources in time of war. So again er the War, while the years of reconstruction saw a reaction inst control, yet the range and the boldness of state action in r, and the magnitude and complexity of the problems of ettlement, left both the theory and the practice of the state re advanced than in the pre-War years. Despite therefore, exceptional conditions of the years of War, the period presents unity in its development greater than at first sight appears. events recede and the period can be seen from a greater tance this will become more evident.

The General Idea of the State.—In judging the position of the eory and practice of government at any period of time it is eful to ask three questions: (1) What changes have there been the general idea of the state? (2) What developments stand t in the forms of government? (3) What is most noteworthy regards the scope and functions of the state? The most damental question is, What change is there in the general a of the state? Three things in this period deserve special phasis. First, the remarkable growth in the sphere of govern- ent. The period might be called that of the changing state, h a great and on the whole steady increase in the functions of vernment. The movement of state and community control, ich had been gaining momentum for over a generation, ex- ds in a wide variety of directions. The movement is universal, smuch as it shows itself in varying forms and degrees in all ntries with a developed system of self-government, and with ighly organised economic life.

Second, there is the growth in the moral idea of the state. ght not might is the valid basis of the state, but the significance of this wins recognition slowly. Yet this period will be seen to mark a great advance in this respect. The state exists to make life good. The idea of social justice reveals itself more fully both in the relations of the individual to the state and in the relations of states one to the other. The challenge to the crude theory of the state as might is made in deed as well as in word. There is a new emphasis on the truths that there can only be one morality for the individual and the state, and that, as the state exists to secure justice, its acts, as much as those of the individual, must conform to common moral principles.

The third aspect is the new emphasis on the value of the individuality or personality of the individual and of the group. The end of the state is the individual. The doctrine of sovereignty becomes less formal and dogmatic. The idea of the community transcends that of the state. For the community embraces the great family of groups and associations which the state must recognise as also sharing with it in the expression of man's social and political nature.

I. FORMS OF GOVERNMENT

There have been in the period very important developments in the structure of government, international, national and municipal. But of these by far the most memorable has been the great international constitution embodied in the Covenant of Nations 1919. The establishment of the assembly and of the council of the League, with their regular meetings and with their important array of permanent and special committees, the organisation of the secretariat of the League, the establishment of the international labour bureau under the Treaty of Versailles, and the creation of the Permanent Court of International Justice, (*q.v.*) are achievements of the highest significance in the history of government. The years 1899–1910, opening with the first Hague Convention, had seen a great advance in international arbitration and methods of peaceful co-operation; the crucial year 1914 had seen the ratification of the first of the treaties between the United States of America and other countries to submit all questions under dispute to a tribunal of investigation before recourse to war; but it is above all to the years 1919 and after that one must look for the foundations of the international polity.

Second, this period has been marked by the importance and variety of developments in government within the British Empire—in itself a league of nations, whose constitutional experience has had a peculiar value for the great world League. The Union of South Africa in 1910, expressed in a constitution distinctive in type from that of the other great federations within the British Empire; in the Government of India Act of 1919, embodying a bold experiment in diarchy; the constitution of the Irish Free State, under the Government of Ireland Act 1922, with the status of a Dominion; and the establishment of the Parliament and Government of Northern Ireland, under the Government of Ireland Act 1920, the first example of legislation and evolution within the United Kingdom, are events of great constitutional interest.

Meanwhile important developments have taken place affecting the general system of relations within the Empire. The imperial conference of 1911—the organisation and work of the committee of imperial defence, the development of the imperial War cabinet in 1917–8, and the conscious advance towards fuller equality of status with the mother country on the part of the Dominions—especially the world recognition of the Dominions and of India as member states in the League of Nations, and the efforts made by post-War conferences to provide more effective methods of imperial consultation and co-operation—mark the period as one of the highest importance in the constitutional history of the British Empire.

Third, this period will be notable for the advance throughout the world in the adoption of representative forms of government and in the progress of democratic ideas and institutions. The political constitutional changes since 1910 in China, including the establishment of a republican form of government, are the most striking indication of the changing East. However superficial and subject to reaction many of these changes may be, they are evidences of the will to learn from the political experience of the West, and, with Eastern participation in international institutions of government, are part of the great movement which is bringing the world closer together.

In Europe itself the World War brought many changes in government, and the new constitutions in Germany, the Baltic States, Poland, Czechoslovakia and Yugoslavia mark the advance throughout Europe of common representative forms of government. In most cases these new constitutions show an acceptance of the cabinet idea of responsible government, but methods of direct popular judgment through the referendum and the initiative have also a wide place in modern European constitutions. Notable also is the widespread adoption, in new and old constitutions, of proportional representation.

It remains to be seen how far the organisation of government on these lines is going to provide a sufficiently strong and stable executive, and how far experience may lead those nations which have adopted the system of parliamentary government to study and follow more closely the British model, which has secured a greater measure of stability and of clearness of responsibility than has resulted from other types of parliamentary government.

Trend Towards a Working Harmony.—In this connection also it may be noted that the trend of opinion, based on experience during the period, has been in favour of the system which secures close harmony between the legislature and the executive. In states where the established system was based on a more marked acceptance of the division of powers, and where, as in Sweden, the constitution presented a " dualistic character," development has been steadily towards greater harmony between the parts of government, giving thereby a more unitary character to the constitution. Even in the United States of America, the great example of the separation of powers, there has been an increasing recognition of the value of closer relations between the parts of government, and the working system of the constitution seems to be moving towards the realisation of this object. In this connection one of the most notable developments has been the adoption of a budgetary system by the Federal Govt. in 1921, as well as by individual states of the Union. In general it may be said that the increasing body of comparative evidence on the practical efficiency of different methods of legislative and administrative organisation is bringing about a closer approximation of the different forms of government one to another, and a clearer understanding of the qualities and defects of each type.

While this has been happening in the progress of a representative government, it is also important to recognise that in this same period there has been a great increase in the critical attitude of mind in almost all advanced countries towards the working of representative institutions. Discontent with parliamentary and congressional institutions has been vocal, and the reaction has expressed itself in various ways. In Russia, with the revolution of 1917 a new system of government, based on councils of soldiers, workers and peasants, has been developed. The challenge of this type to the established representative system of parliamentary government has not so far succeeded in the states of Central and Eastern Europe which have given themselves new constitutions since 1918. On the other hand, especially in the Southern European states, the reaction against the weakness and corruption of government has led to the establishment of a series of dictatorships which, even when they maintained the form of parliamentary government have denied it the substance of power. These reactions from representative government are significant. War increases the strength of the executive, and the experience of the first years of peace emphasised the need of authority and leadership. But, apart from this, there has been a growing recognition that, even in normal times, good government in democratic States requires clearness of responsibility and the power to act, and that in many cases representative institutions, parliamentary and congressional, have dissipated power and obscured responsibility.

Functional Representation.—In another direction, closely related to the foregoing, the period has also shown interesting developments in the growth of ideas and of institutional f expressing what is called functional representation. The s of thought which has given prominence to these ideas has more extreme expression challenged the authority of a p mentary system based on regional representation, and has sc to replace this by methods which would directly reflect opinions of the various economic and social groups withi community. The vogue of this school of thought has been not simply to dissatisfaction with the working of the exi forms of representative government, but also to a sense o importance of securing the expert knowledge of the group and of giving to the groups the largest measure of self-go ment and control in the development of their functions.

In practice, the great increase in the organisation, not on industrial and economic but of social and cultural groups w the body politic, extending often beyond national bound has influenced the institutions of government, local, nat and international. Nowhere is this more clearly seen than i formation of representative councils or committees, us consultative, but in some cases invested with considerable s tory authority, which have been associated with the p departments of administration in Great Britain. In Gern the place given in the new constitution to the economic co of the empire is an expression of the same tendency. This not, however, involve the overthrow of the well-establi forms of representative government. Gradually the adjustr of the new to the old order is taking place, and the theor representative government is thereby enriched and strengthe For there is no alternative to representative governme democracy is to survive in the modern world. Such at seems to be the trend of progress through the changing com of political, social and economic conditions.

It is worthy of note also that in this political evolution the going on a process both of centralisation and decentralisat In all federal states there has been during this period a ma growth in the power of the central government, while in st with a more unitary type of constitution, like Great Britain France, methods of devolution and of regional reconstruc have been making headway. But in both types, centralisa and decentralisation are actively proceeding, a consequenc the growth in the functions of the state and of clearer differ ation of the powers which should belong respectively to l national and international authority.

Nor should the increased attention in this period to local ernment, urban and rural, be overlooked. Nowhere have d opments in this field been more significant than in the Un States. The great amount of experiment in that country in forms of municipal government indicates a more active pe of interest in local affairs, while the progress of the munic home rule movement is a further expression of the democ idea that government must be decentralised, and that the s of local responsibility has to be safeguarded in the great mo nation state. Thus this period has brought forth import developments in international, federal, national and local ernment. It will stand out also as one in which the nations h been coming nearer to one another in constitutional thought in forms of government.

II. FUNCTIONS OF THE STATE

The years 1910–25 have seen a great extension in the funct of the state. In the last quarter of the 19th and to an increa degree in the first decade of the 20th century the state has b abandoning the policy of *laissez faire*, and building up a structive plan of community action, aiming at better social economic standards of life. In education, in public health provision for housing, in factory and workshop standards the regulation of industrial disputes, in the developmen municipal services, the new idea of the functions of the state being progressively revealed. The years 1906–10 opened rich fields of state activity; and 1910–4 saw further import developments, which, however, were checked by the outbr of hostilities.

xtension of State Activity.—In Great Britain the establish- it of the development commission and of the road board ked a new constructive policy of state aid. Thus, the re- ces placed at the disposal of the development commission bled a comprehensive scheme of agricultural research to be ertaken, while later the establishment under the Privy Coun- f the committee for scientific and industrial research, and of medical research committee were further recognition of the t and growing function of the state in this sphere. The road rd was also the forerunner of developments of state policy o-ordinating and controlling transport, culminating in later s in the establishment of a ministry of transport. So again pre-War years saw the establishment of national health in- nce and the first steps in the development of unemployment rance under the National Insurance Act of 1911.

he outbreak of war led to a great extension of state functions. ntary methods gradually gave place to state control. The lation of man power, the control of imports and exports, the onalisation of the supplies of munitions, the regulation of cultural production, the rationing of food supplies and of materials for industrial requirements—these and other meas- of state action demonstrated the power of state organisation me of war. Peace brought with it a reaction. Nevertheless, r the War there remained a wider idea of community right obligation. The gravity of the problem of unemployment to measures of relief by central and local authorities of a acter and amount hitherto unknown. The state has also called upon to exercise extended functions in relation to the onal resources of coal, power and transport; while the devel- ent of a much more comprehensive policy for the assistance griculture and forestry and the establishment of the Food ncil are indications of the steady growth in state function.

oluntary Effort.—But side by side with the growth of gov- nental power is the increase in voluntary economic and social nisation, and in the association of voluntary with statutory es in the work of government. There is great significance for future in this renascence of voluntaryism. It marks a new e in the development of government, in which not simply he people by their votes choose their rulers, but in which to ncreasing extent they are associated with the administration overnment in its many branches. The state is becoming e flexible. The organisation of the community is proceeding, simply by bureaucratic efficiency, but by the democratic hod of making the people experience to an increasing extent, ugh voluntary organisations, the part which they alone can n the work of government.

Just as the theory of *laissez faire* had to yield to changing conditions, so the theory of a socialistic state, meaning thereby state ownership, state operation and state control, is giving place, at least in the Anglo-Saxon countries, to a conception of community life, in which there is not only room for individual and voluntary organised effort, but in which it is seen that the increase of state action to be really effective and desirable has to be accompanied by a growth in the more flexible forms of association which come under the category of voluntary and self-help movements. It may well be that, as the Anglo-Saxon race has contributed beyond any other people to the development of representative institutions of central and local government, so the political genius of the race may reveal the part which voluntary associations have to play in the development of democracy and in the meaning of community life. In all these respects the period 1910–25 is significant in the history of government. (*See* SOCIAL SERVICE.)

BIBLIOGRAPHY.—The main sources of evidence for the study of modern governments are to be found in the official records of parliamentary proceedings in the several countries and in the reports of the administration departments and of special commissions on committees of inquiry. For the text of the constitutions W. F. Dodd, *Modern Constitutions* (1909) and P. Dareste, *Les constitutions modernes* (1910) are the most convenient collections while the most useful source for the post-War constitutions is the *Jahrbuch des öffentlichen Rechts* (Tubingen). As regards general studies of modern government, Viscount Bryce, *Modern Democracies* (1921); A. Esmein, *Éléments de droit constitutionnel français et comparé* (1921) and G. Jellinek, *Allgemeine Staatslehre* (1922) are of standard value. A wide range of studies of government in War time has been issued by the Carnegie Endowment for International Peace. A useful series of studies in governmental organisation is published by the Institute for Government Research (Washington, D.C.). (W. G. S. A.)

GRACE, WILLIAM GILBERT (1848–1915), English cricketer (*see* 12.308), died at Eltham, Kent, Oct. 23 1915. His elder brother, EDWARD MILLS GRACE (1841–1911), died at Thornbury, Glos., May 28 1911. See F. S. A. Cooper, *W. G. Grace, Cricketer* (1916), Lord Hawke and others, *The Memorial Biography of Dr. W. G. Grace* (1919).

GRAF, ARTURO (1848–1913), Italian poet and critic (*see* 12.315), died at Turin May 29 1913. *Poesie*, a collection of his best poems, appeared in 1915.

See Sartori Treves, *Arturo Graf, romanziere e poeta* (1904).

GRAIN ELEVATOR.—The term elevator has been universally adopted on the North American continent to describe a granary consisting of deep bins or silos, the grain being elevated to the top of these bins for the purpose of filling them. It is also commencing to be generally used by such other countries as have adopted this method of grain storage.

The grain elevator is the natural outcome of the bulk-handling

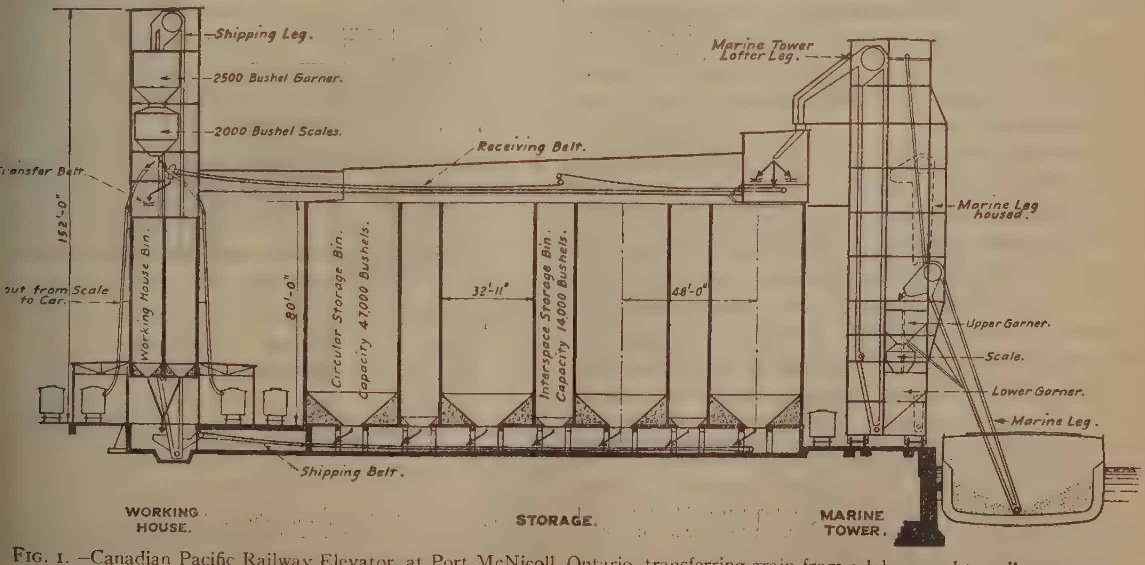

FIG. 1.—Canadian Pacific Railway Elevator, at Port McNicoll, Ontario, transferring grain from a lake vessel to railway cars. Its storage capacity is 4,000,000 bushels.

system as distinguished from the bagging system, and it is this that makes it possible for a port, equipped with up-to-date elevators and grain galleries, to receive and ship out such vast quantities of grain as are handled at Canadian and United States ports, of which Montreal holds the premier position with an export record of over 4,000,000 tons per annum. Previous to the introduction of the bulk-handling system, grain was, and still is, in many countries, handled in bags. To attempt to handle a large grain crop in bags is about as economical as supplying city water in buckets instead of water mains. Grain is a semi-fluid material, and the bulk-handling system uses this fact.

Distribution of Elevators.—Although Canada and the United States are still the only countries in which grain is handled entirely in bulk through elevators, there has been a noticeable movement toward this method in several other countries and already there are examples of up-to-date elevators in Europe, Australia and the Argentine. Russia has a few dotted over her vast grain territory, and South Africa has also made a commencement. The complete bulk-handling plan adopted by the New South Wales Govt. with its chain of elevators from the grain growing districts to the ports and a 5,500,000 bushel terminal elevator at Sydney, is the most complete example of a bulk-handling system of elevators outside North America, the entire system having been constructed under the supervision of the Metcalf Co. of Montreal. The two elevators at Manchester and also that at Dock One, Buenos Aires, are examples of this type by the same company.

Capacity.—The storage capacity of the elevators of the United States is approximately 1,000,000,000 bu.; that of Canada 250,000,000 bu. and the portion of the Australian system already completed 20,000,000 bu., whilst the entire up-to-date elevator storage of the remainder of the world probably does not exceed 5% of the totals of those countries.

Construction.—Until about the end of the 19th century, elevator bins were almost universally constructed of wood, but about that time a demand for a fireproof form of construction began to be felt, owing to the heavy losses by fire and, to some extent, to the increasing price of timber. Steel plate and also tile bins commenced to take the place of those of wood, but this era did not last owing to the introduction of reinforced concrete, which has become practically universal for this class of building.

Use of Concrete.—Since the adoption of concrete as a material of construction, the size of elevator bins has been considerably increased. Circular bins of over 30 ft. in diameter are quite common, and the depth has been increased to as much as 110 feet. The square form of bin, which was almost essential in wood construction, has been largely superseded by circular concrete bins. Another marked advance since 1910 is the general adoption of individual motor drives to all units of machinery, such as belts and lofter legs, and the substitution of silent chain or double-helical gears as a means of power transmission in place of the rope drives formerly used.

Car Dumpers.—One of the most drastic changes in American elevators for many years has been in the method of unloading grain from railroad cars. Until quite recently this was done by means of power shovels. The inner grain door of the car was removed by means of a crowbar and frequently destroyed in the process. Two large scoops or shovels were then carried to the ends of the car by hand and automatically drawn back by ropes operated by drums on the line shaft. This method, although still in general use, entails considerably more man power and more time than is at all in accordance with modern ideas on grain handling. The mechanical car dumper, which automatically opens the grain door without damaging it and dumps all the grain out through the doorway of the car without any manual labour, is being rapidly adopted in the newest types of elevators.

The operation of the Metcalf car dumper is as follows: The car to be unloaded is hauled on to a platform about 58 ft. long, over rails which are in line and continuous with the track rails at either end of this platform. The car, having been run on to this platform, is automatically clamped in position. The platform, with the car, is then raised 10 ft. by means of wire cables,
and simultaneously tilted sideways through an angle of 14°
the grain door rammed in. The platform with the car upon
then tipped endways, first in one direction and then in the ot
until all the grain has run out into a pit with a hoppered bot
below rail level. The grain is drawn off from this pit on to a
conveyor, is conveyed to an elevator leg, carried up to sc
above bins, weighed and distributed in the usual manner.

One of these car dumpers is capable of unloading seven 2,
bu. cars per hour, and as there are batteries of four dumper
the Harbour Commissioners of Montreal Elevator No. 3,
Baltimore and Ohio Railroad Company's elevator at Baltim
and the Santa Fé Railroad Company's elevator at Ka
City, each of these plants has an unloading capacity of 28 t
per minute. (L. C. H

GRAIN PRODUCTION AND TRADE (*see* 12.322).—Accor
to the official statistics furnished to the International Instit
of Agriculture, the production of cereals in those countries
which figures are available during the period was as follows

World Production of Principal Cereals (Russia and China excluded) Millions of cwt.

	Average 1909–13	Average 1919–23	1923–4	1924–5	1925
Wheat . .	1,590	1,621	1,836	1,627	1,75
Rye . . .	503	410	447	357	49
Barley . .	486	415	487	442	52
Oats . . .	980	948	1,062	1,019	1,09
Maize . .	1,705	1,713	1,804	1,527	1,75
Total . .	5,264	5,107	5,636	4,972	5,61

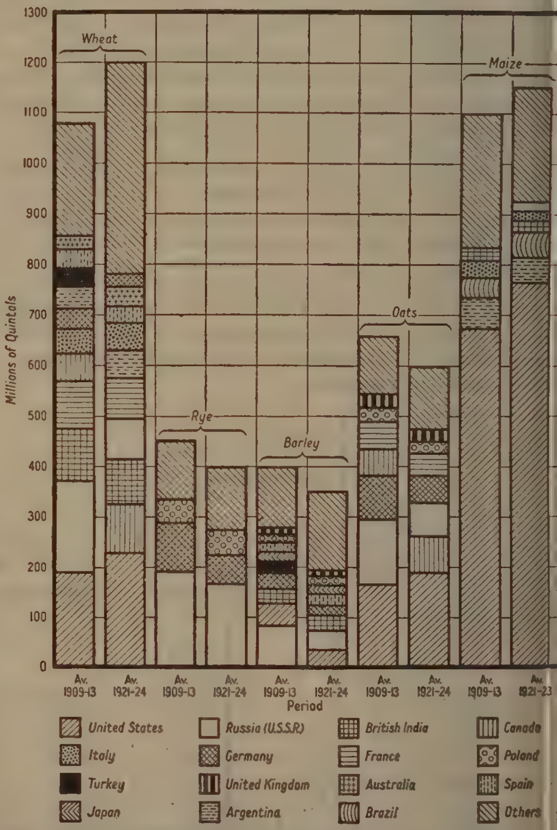

FIG. 1.—Diagram showing the average annual world production
Wheat, Rye, Barley and Oats, for the period 1909–13 to 1921–4, a
of Maize for 1909–13 to 1921–3. The production in the princi
producing countries for which figures are available is indicat
"Others" includes the production in Egypt, Hungary, Mexi
Rumania, Yugoslavia and the other minor producing countries, a
an estimate of production in those countries for which no figures a
available. The diagram is based on figures given in the Internatio
Yearbook of Agricultural Statistics for 1924–5.

These statistics do not include the crops of Russia or China, t they give an approximate indication of the yields in the rest the world. Apart from those two countries, the world's pro- ction of these five cereals taken together on the average of the e years after the Armistice was nearly up to the pre-War erage. In 1923–4 the world had an exceptionally good crop of eals, 7% above the pre-War average, but in the following year 24–5 the yield was poor, being 6% below the pre-War average. 1925–6 the harvests were exceptionally good, 13% better n in 1924–5, practically equal to the good yield of two years ore, and 7% above the pre-War average. According to official tistics furnished for Soviet Russia, its average yield of these e cereals for the five years before the World War was 1,247, 000 cwt., in 1924 it was only 767,000,000 cwt., and in 1925–6 reased to 1,069,000,000 hundredweight. This last estimate s perhaps too sanguine, as the Russian harvests suffered from l weather; but it may be said that for the world as a whole, luding Russia, the yield of these five cereals in 1925 was much ter than it was in 1924, and somewhat higher than the pre- r average.

hese five grains form a large proportion of the food of the abitants of the temperate regions, but perhaps nearly as much in in the form of rice and millet is consumed by the inhabi- ts of the tropical and sub-tropical countries. The world's ld of rough rice (excluding China) in 1924 was 1,613,000,000 ., as compared with 1,413,000,000 cwt., the pre-War average, l if statistics for China were available it would appear that the world as a whole the weight of rough rice produced is ater than that of wheat. Of that quantity 132,000,000 cwt. s exported, as compared with the wheat export of 430,000,000 ndredweight.

I. THE WHEAT YIELD

ield.—The yield of wheat in those areas for which compar- e statistics are available was approximately as follows:—

Yield of Wheat in Millions of Quarters of 480 lb.

Area	Average 1909–13	Average 1919–23	1923–4	1924–5	1925–6
ırope (excluding Russia)	167·8	135·5	155·0	130·2	170·7
orth America	112·3	145·1	160·7	143·2	137·7
sia	48·7	49·0	52·0	50·8	46·8
rica	12·5	12·4	14·1	11·4	14·5
gentina	18·4	23·5	31·0	23·9	26·8
ıstralia	11·3	12·7	15·6	20·2	12·5
Total (excluding Russia)	371·0	378·2	428·4	379·7	409·0
viet Russia	94·2	..	..	47·7	82·7
Total (including Russia)	465·2	..	..	427·4	491·7

hese figures do not include China and a number of unimpor- countries, and it may be roughly estimated that on the pre- average the whole world produced about 490,000,000 quar- . The statistics for Soviet Russia are not very trustworthy, if they be included, the totals indicate that, for the world whole, the wheat harvest of 1925–6 is considerably above the War average. For the countries other than China and Soviet sia, it appears that on the average of the five years after the the yield of wheat was about equal to the pre-War average. the average of the three years 1922–3 to 1924–5 their yield 405,700,000 qr.—that is, 9% above the pre-War average. a comparison be made between the average pre-War yield the average yield of 1922–3 to 1924–5, it appears that the age yield of Europe (excluding Russia) has decreased from to 152 million qr., and there is a very large but indeter- te decrease in the yield of Soviet Russia. The average ls of Asia and Africa were much the same as before; but was an increase in Canada from 25 to 48 million qr., in United States from 86 to 97 million, in Argentina from 27 million, and in Australia from 11 to 16 million. These ases more than made up for the decrease in the average yield of Europe and Soviet Russia. The average yield of wheat in the whole world may be therefore roughly reckoned at about 500 million qr., of which about 50 million qr. are grown in the Southern Hemisphere and reaped in Dec. and Jan., while the remaining 450 million qr. are grown in the Northern Hemisphere and reaped at various times between March and October.

Import and Export.—As the production and consumption of wheat are much more important in the Northern than in the Southern Hemisphere, it is convenient to adopt for the world's cereal year the 12 months ending with July, just before the principal new harvests are reaped north of the equator. For cereal years so calculated the following statistics give approximately the net imports and the net exports of different areas, flour being reckoned as wheat at the rate of three of flour equal to four of wheat.

Net Imports of Wheat in Millions of Quarters

Area	Average 1909–14	Average 1914–9	Average 1919–22	1922–3	1923–4	1924–5
Importing countries of Europe	69	..	69	70	70	80
Non-European countries	13	..	12	17	30	13
Total imports	82	69	81	87	100	93
British Isles	27·0	23·9	25·6	27·0	29·0	28·3

India	6·2	3·7	Nil.	3·6	2·5	4·7
Total all exporting countries (including others not mentioned above)	82	70	81	87	100	93

Apart from the years of war, the demand for wheat from abroad of all the importing countries of the world was, on the average of the three years after the War, much the same as it was on the pre-War average, but on the average for the three cereal years completed in 1925 it increased from the pre-War 82 to 93, having risen to 100 in 1923–4, when wheat was cheap owing to the exceptionally good harvests of that year, and fallen again to 93 in 1924–5, when the price of wheat had risen owing to comparatively poor harvests.

The demand of the British Is., which import about 30% of the whole world's surplus for export, remained remarkably steady, notwithstanding great fluctuations in price, and averaged 28,000,000 qr. for 1922–5, *i.e.*, from Aug. 1 1922 to July 31 1925, as compared with the pre-War average of 27,000,000 quarters. Belgium and Holland taken together imported an average of 8,200,000 qr. as compared with their pre-War average of 8,900,000 quarters. The demand of France, Italy and Germany, which produce a large proportion of the wheat they require for their consumption, varies considerably. On the average of the years 1922–3 to 1924–5 France's import was 5,400,000 qr. compared with the pre-War 5,500,000, but it rose to 6,500,000 in 1923–4, when prices were low, and fell to 3,900,000 in 1924–5, when prices were high. Italy's import averaged 11,500,000 qr., against the pre-War average of 6,600,000 for a smaller population, but it was considerably higher in 1922–3 and 1924–5, when Italy had poor harvests, than in 1923–4, when she had a very good harvest. Germany's average import was 6,100,000 as compared with the pre-War average of 8,500,000 qr. for a larger population; and it was only 3,700,000 in 1923–4, when her own harvest was fairly good but her currency was disorganised, and rose to 9,900,000 in 1924–5, when her harvest suffered greatly from wet weather, and her exchange was on a better footing. Greece, with her increased population, has raised her average import from 900,000 to 2,300,000 quarters. Egypt's average is much the same as pre-War. Japan has raised her average from 500,000 to 2,200,000 qr., but this includes the exceptional import of 3,500,000 qr. in 1923–4, due chiefly to the effects of the great earthquake.

The many importing countries outside Europe, for which detailed statistics are not available, including China, Brazil and other tropical and sub-tropical areas, have apparently imported on the average of 1922–3 to 1924–5 about 20,000,000 qr. against the pre-War average of 13 million. They are even more ready than the European countries to increase their consumption of wheat when it is cheap and to lessen it when it is dear, and they imported much more wheat in the cheap year for wheat 1923–4, when rice was comparatively scarce and dear, than in the year before or the year after, when wheat was dearer and rice cheaper.

As regards the exporting countries, the most remarkable feature was the disappearance of Russia as an exporter. Before the War the Russian Empire on the average produced 102,000,000 qr. of wheat, more than one-fifth of the world's total yield, and exported annually 20,500,000 qr., one-fourth of the world's exports. On the average of the three years after the War, she imported 3,000,000 qr., largely as famine relief, and during the three years 1922–3 to 1924–5 she imported nearly as much as she exported. In the year 1925 she had a much better harvest. The Danubian countries also, Rumania, Bulgaria, Yugoslavia and Hungary, which before the War had an average export of 13,200,000 qr., on the average of those three years exported only 2,400,000, their average yield having fallen off from 39,200,000 to 30,000,000 qr., no doubt owing largely to the impoverishment caused by the War and to the partition among the peasants of the large estates, which formerly furnished a great part of the exports. India had before the War an average yield of 43,800,000 qr., and an average export of 6,200,000 quarters. During the five war years her average yield was 44,000,000 and she exported an average of 3,700,000 quarters. The three years 1919–21 included two poor harvests—the average yield was only 37,800,000 qr., and there was practically no net export; but the three years 1922–4 were years of good harvests, with an average yield of 45,600,000 and an average export of 3,600,000 quarters. This makes the average consumption of these three years about 42,000,000, against an average pre-War consumption of about 38,000,000 quarters. Apparently India utilised her increase of prosperity to increase her consumption of wheat, more especially as during part of that period wheat was unusually cheap and rice unusually scarce and dear.

While Europe and Asia thus failed to maintain their former supply of surplus wheat, the deficit was more than made up by North America, Argentina and Australia, although their exports varied greatly from year to year. During the five war years Canada increased her average export from 11,800,000 to 19,700,000 qr., the United States from 13,400,000 to 27,500,000 qr. and Argentina from 10,300,000 to 11,900,000 quarters. Australia's average export remained about 6,600,000 qr., the difficulty of transport over such a great distance in time of war having made it impossible to export the whole of her surplus. On the average of the three years 1919–20 to 1921–2 Canada exported 18,400,000, the United States 31,300,000, Argentina 18,700,000, Australia 12,500,000 qr.; and on the average of the three cereal years 1922–3 to 1924–5 their exports were, Canada 34,500,000, the United States 21,000,000, Argentina 18,100,000 and Australia 10,600,000 quarters. Thus on the average of these three years the requirements of all the importing countries of the world, amounting to 93,000,000 qr., were supplied approximately in the following proportions: Canada 37%, United States 23%, Argentina 19%, Australia 11%, India 5%, other countries 5%.

Consumption.—If it be assumed that the consumption of a country during a cereal year is represented by its yield plus or minus the quantity imported or exported, the following statistics give a rough idea of the consumption of certain countries
which comparable statistics are available:—

Consumption of Wheat in Millions of Quarters

Country	Average 1909–14	Average 1914–9	1922–3	1923–4	1924–5	Avera 1922–
British Isles	34·4	32·7	35·2	36·5	35·0	35·6
France	45·1	36·8	36·1	40·9	39·0	38·7
Italy	29·5	30·2	34·6	36·9	32·5	34·7
Germany	27·5	...	13·7	16·7	21·1	17·2
Canada	12·8	12·1	13·6	16·2	13·1	14·3
U.S.A.	72·3	75·2	85·0	83·5	82·7	83·7
Argentina	8·0	8·3	8·5	8·5	8·5	8·5
Australia	4·7	7·2	6·4	6·5	6·0	6·3
India	37·6	40·2	42·2	44·1	40·8	42·7

During the World War the importing countries of Europe h
great difficulty in obtaining the wheat they required from abroa
and took special measures to reduce the consumption of whe
and as a result of these measures, and of the great rise that to
place in the price of wheat, several of those countries conside
ably reduced their average consumption. For the British Is. t
pre-War average of 34,400,000 fell to an average during the W
of 32,700,000 quarters. On the average of 1923–5 it rose to 3
600,000 qr., while the population increased from 45,200,00
1911 to 47,400,000 in 1921. During the War the French co
sumption was reduced from the pre-War average of 45,100,0
to 36,800,000 quarters. For 1922–3 to 1924–5 it only ave
aged 38,700,000 qr., although the population (including Alsa
Lorraine) was practically the same in 1922 as it had be
in 1911. On the other hand, the people of Italy found it diffic
to keep down their consumption of wheat, and during the W
the average annual consumption increased from 29,500,000
30,200,000 quarters. For 1922–3 to 1924–5 it averaged 34,700,0
qr., the population having increased from 34,700,000 in 1911
39,700,000 in 1923. The consumption of wheat per head
Germany is much less than it was before the War, as, accordi
to the statistics, the average consumption of 1922–3 to 1924-
for a smaller population was only 17,200,000 qr. as compar
with the pre-War average of 27,500,000 quarters. Canada a
the United States, with an increased population, consumed c
respondingly increased quantities. Australia during the W
was unable to export the whole of her wheat surplus, and mu
of it was wasted or was still in the country at the end of the W
Her average consumption for 1922–3 to 1924–5 was 6,300,0
qr. as compared with 4,700,000 qr. before the War, owing chi
to increase of population. India also had difficulty in exporti
her wheat surplus during the War, and her consumption the
fore increased. For 1922–3 to 1924–5 it averaged about 42,00
000 as compared with the pre-War average of 38,000,000 q
although the increase of population between 1911 and 1921 w
only from 315,000,000 to 319,000,000.

The Question of Price

The price of wheat varies greatly according to its variety, clea
liness, purity, uniformity, strength and condition. It also vari
often very rapidly, with reported changes in the world's weather a
expected changes in the relation between the world's supply and t
world's demand. The cost of ocean freights is another factor in t
calculation. The pre-War average freights on wheat imported in
the United Kingdom were approximately per qr. of 480 lb.: from Ne
York 2s., from Buenos Aires 3s. 6d., from Karāchi 4s. and fro
Australia 7s. The pre-War average prices of wheat, in importi
countries, after deducting import duties, were approximately, p
quarter of 480 lb.: Britain, home-grown 32s., imported 35s.; Fran
32s.; Italy 33s.; Germany 32s.; and Austria 37s.; and in expor
ing countries—Russia 33s.; United States (Chicago) 30s.; Cana
(Winnipeg) 30s.; India (Karāchi) 31s.; Argentina (Buenos Aire
31s. and Australia (Melbourne) 31s. Owing to the cheapness
ocean freights there was no great difference in the average pric
in importing and in exporting countries; and hardly anywhere
the world, except in places far from the sea, or in countries whe
there was a high import duty, was the pre-War average price
wheat below 30s. or above 35s. a quarter.

During the War, owing to the destruction or immobilisation
many ships, to urgent military requirements and to the increase
risks, there was a great rise in ocean freights, and after a time t
British Govt. took control of the whole merchant shipping of

ire and of the arrangements for the import of wheat, not only Britain, but into the Allied countries also. At the date of the istice freight rates being paid for wheat per qr. to the United dom were—from New York 50s., from Buenos Aires 48s. and Karāchi 53s. After the Armistice the control of shipping was tained for a considerable time, but the rates of ocean freight fell rapidly, and by Dec. 1920 (when the movements of shipping practically freed from control) the rates were approximately— New York 8s., from Buenos Aires 8s. 7d., from Karāchi 9s. 1d. from Australia 22s. 6d. After that date there was a further fall in these rates, and in Nov. 1925 they were approximately— New York 3s., from Buenos Aires 3s. 4d., from Karāchi 4s. 3d. rom Australia 8s. 9d.—that is to say, freight rates were not very higher than before the War, and as prices were about 55 % r than before the War this meant that shipowners in 1925 ght wheat to Britain on payment of only about two-thirds of re-War value in commodities. This great fall in the commodity of freight rates was no doubt mainly due to the fact that the l's gross tonnage of seagoing steel and iron steamers had in- ed since 1914 by 38 %, while the quantity of merchandise ring cargo space was less.

order to trace the course of the world's price of wheat during eriod 1913–25, it will be sufficient to quote the prices of wheat t the middle of Nov. (when it is usually possible to frame an oximate estimate of the yield of the harvests in the northern sphere and of their probable yield in the Southern Hemisphere) hicago and Winnipeg as representing the exporting countries, or London or Liverpool as representing the importing countries, hich may be added the average price obtained about that date rmers in England and Wales for home-grown wheat, according e corn trade returns.

Price of Wheat about Nov. 15

ear	Chicago cents per 60 lb.	Winnipeg No. 1 Manitoba, cents per 60 lb.	London or Liverpool No. 1 Manitoba, shillings per 480 lb.	England and Wales Home-grown shillings per 480 lb.

3 .	105	97	44	40
4 .	156	167	66	54
5 .	164	140	55	48

iring the War the price of wheat rose rapidly both in exporting n importing countries. After the Armistice, the price of wheat nued to rise for a time, and in July 1920 wheat sold both in ıgo and Winnipeg at about 280 cents per bushel—more than times its pre-War price. Soon after that date government con- egan to be removed and freights and prices rapidly fell, and by 1921 the price of wheat at Chicago was only 119 cents per l and at Winnipeg 111—that is, only about 35 % above the Var average. In the following two years there was a further and in Nov. 1923 the prices quoted were at Chicago 105 and nnipeg 97—that is, less than 20 % above the pre-War price. arly in the British Is. the price of wheat rose until in Nov. 1920 Manitoba wheat was being supplied by the Govt. at 116s. r., and the British farmer was being paid about 90s. per qr. for -grown wheat. These prices again were about three times the Var prices, but it must be remembered that they were reckoned erling, and that in that year the British paper pound was only about 75 % of the gold sovereign. After control was removed was a very rapid fall in the price, and by Nov. 1921 Manitoba t was selling in Liverpool at 50s. per qr. and British wheat was t 46s.—that is, about half the price obtained 12 months before. e was a further fall of price in the following two years, and in 1923 Northern Manitoba wheat sold at 44s. and British wheat s. per qr. or only about 30 % above the pre-War price.

ese very low prices in 1923 were no doubt mainly due to the tionally good harvests of that year, both in Europe and in the as a whole, and to the impoverishment of the importing ries of Europe. The low price continued through the winter 23–4; but after May 1924 drought developed in south and eastern Europe, and Canada and central and northern Europe ed a cold, wet summer, and it became evident that the harvest in Northern Hemisphere as a whole would be a poor one. The price of wheat accordingly rose rapidly until at the end of 1925 the price of No. 1 Manitoba in Liverpool was 76s. 6d.— above its price 12 months before. It then came to be realised that this price was higher than was justified by the prospects, and the price fell rapidly in March and April to about 60 shillings. In consequence of the good harvests of 1925 in the Northern Hemisphere it fell further to 55s. in the middle of Nov. 1925, but then rose again owing to the disappointing harvests in the Southern Hemisphere, and in Jan. 1926 was about 62s.—almost double the pre-War price, while the British farmer was getting 53s. a qr. for his home-grown wheat—about 70 % above the price of 1913.

(J. Wi.*)

II. THE GRAIN MARKETS

Great Britain is the only country where the demand for imported wheat is constant and extensive. There are many others which import wheat from time to time, but merely by way of supplement to their home-grown food crops. These circumstances have resulted in the establishment of the London grain trade in the commanding position of the chief market of the world, primarily for wheat business, but also for maize, oats and barley. It is not only for delivery in London itself that this trade is done. A very large portion is for other destinations, and cargoes for ultimate discharge in Scotland, Ireland or Wales, at Dutch, Belgian or German ports, or even in the Mediterranean, are bought and sold by London brokers, on the accustomed basis of London contracts. A considerable business in grain from overseas which does not enter London is registered daily in the grain trade journals, cargoes of wheat and maize forming the greater portion.

The usages and terms of the London market are matters within the competence of the London Corn Trade Assn., a corporate body including members of all grain trade firms of consequence, in Great Britain, on the continent of Europe, and among exporters from North and South America, from India, Australia and Africa. Brokers and traders in all the principal towns of Britain, and millers with establishments in many parts of the world, find it advantageous to belong to the London Corn Trade Association. Most of those not strictly connected with London are also members of their own local associations, of which the Liverpool Corn Trade Assn. is the most important, and is followed by those of Hull, Bristol, Leith, Antwerp, Hamburg, Genoa, etc. The main object of these associations is the protection of the common interests, by defining terms of contract, by providing for arbitration in cases of dispute, and by taking measures to uphold the rights of traders against infringement. The predominance of North America among the grain markets of the world is an outstanding fact, and it is not too much to say that the wheat quotations of Chicago and Winnipeg are those most regarded as deciding the course of the world's grain trade from day to day. In some seasons the Chicago price is all-important, in others it shares supremacy with Winnipeg. The qualities quoted are so well known that is is needful only to mention No. 2 Winter or No. 1 Manitoba in order to afford a definite basis of transactions. In this respect the business in North American grain is done on terms differing from those adopted by other exporting countries.

In the United States and in Canada the system of government inspection of grain for settling grades is very efficient, and the certificate of the government inspector is accepted as final. By far the greater part of the grain business in the United States is in connection with produce intended for internal consumption or manufacture, and the terms agreeable to American buyers have therefore to be accepted by exporters from the United States. In Canada the relative size of overseas trade is much greater, but the system of inspection and grading is even more precise than in the United States, and is accepted by exporters. In dealing with Argentina, whence the tropical passage may cause the grain to deteriorate on the voyage, the contract basis throws this risk on the shoulders of the exporter in South America, and wheat is sold with a guarantee of natural weight to be verified at discharge of the grain. Wheat from Australia is sold as fair average quality at time and place of shipment, and similar stipulations are made in the special contract form for Indian wheat, with a guarantee in case of damage by weevil, or deterioration by the excessive mixture of barley or any other extraneous matter.

By far the larger portion of the world's wheat crops finds its way to the flour-mill, though some considerable quantity is used for cattle or poultry food. The miller, therefore, may be set down as the ultimate buyer of wheat. With the gradual consolidation of mills under the management of a few leaders of the industry, each of these millers has become, individually or in his corporate capacity, a very important factor in the grain trade. He is, in most cases, the original buyer of grain for British ports, to be discharged direct from the ship into his warehouse communicating with the mill by grain elevators and conveyors. In the British grain trade of to-day there is very little scope for the merchant who formerly purchased a wheat cargo for apportionment in suitable quantities amongst millers. The miller does not manufacture flour entirely from one cargo, or even from one sort of wheat. In the ordinary way, when supplies from various exporting countries are plentiful, he will probably mix three or four different kinds, in carefully defined percentages, in order to provide the baker with just such flour as he has been accustomed to sell to the public.

In most of the exporting countries there are well-established firms who employ agents to buy from the farmers, and thus collect adequate quantities for loading their chartered ships. In countries such as Canada and Australia the farmers themselves have formed pools or syndicates, with managers who negotiate with exporters. In the United States, grain export business is so interdependent with future trading that it may be more conveniently treated under that heading. With the exception of relatively small parcels of wheat, very little is sold on the corn exchanges after arrival. It has become the practice for millers to buy, even for their minor requirements, when the grain is still overseas or on passage. It is also customary for bakers to contract two or three months ahead for flour to be delivered, and these contracts are sometimes made with Canadian, Australian and American millers.

Futures.—Apart from direct sales of overseas wheat to millers, considerable business is done by traders who buy wheat for shipment and, either immediately or later, sell a similar quantity for delivery at a future period. This future delivery trading, known also as *marché à terme* or *mercado á término*, originated in the United States and has been established at Liverpool for nearly half a century. It was adopted at Buenos Aires in 1908 and is now carried on at Winnipeg. There are future delivery exchanges, including grain contracts, at Antwerp, Paris, Berlin, Genoa, etc. At Chicago and Buenos Aires futures trading is established for wheat, maize and oats; at Winnipeg for wheat and oats; in all three and in Liverpool wheat absorbs the chief attention. It may be considered as essential that, to avoid cornering, a future delivery exchange should have an ample available supply of such qualities of wheat as are in favour with millers; in other words, the exchange should be located on a main route of transit between the grower and the consumer. Unless this condition is fulfilled the business organisation seldom succeeds.

By means of one or other of these exchanges the farmer can, if he chooses to do so, sell his crop of wheat whenever the price suits him, months before it is ready for the reaper, and thus practically eliminate any risk of falling prices. The miller who has purchased a cargo of wheat can sell an equal quantity in the form of contracts for future delivery. Naturally, he will not find this course desirable unless there is an apparent profit between the price paid for his cargo and that obtainable for future delivery of wheat. He has also to buy wheat for his mill, and if he sells the contracts for future delivery his next enterprise is to sell the flour to be manufactured later, and as he achieves this to buy in his wheat contracts. He thus makes four transactions in place of the simple purchase of wheat abroad and the sale of flour at home. He has safeguarded himself against market losses, and is ready to continue his day-to-day disposal of the flour. It will be noted that in selling wheat for future delivery in a given market he has to rely upon others for fulfilment of these wheat contracts, for he does not intend to deliver from his purchased cargo; hence it is clearly his aim to deal only on markets where there is a steady influx of wheat.

This series of transactions needs only to be multiplied indefinitely, and attributed to traders who are not millers, in order to form a basis of opinion on the grain futures markets. Speculation of course exists, and may carry prices too high or too low. Fluctuations in quotations for future delivery are often extreme and very rapid, for on receipt of some information affecting crops the first interpretation of its meaning is shown in the future delivery market. Sharp fluctuations are not, however, always misfortunes. The purchaser of a wheat cargo who has duly sold futures against it may find that his contracts for sale can be repurchased at a discount of say 3%, and that he can resell his cargo at a discount of 2%. He may probably do the business both ways and come out with a net profit of 1%; he sacrificed 2% on the original price of the cargo, but the sacrifi more than compensated by the 3% gain on the future delivery

Future trading involves, in effect, a daily settlement by seller buyer alike of difference in price arising from market fluctuati and a payment by both parties at the time of making the cont of a cash margin according to the regulations which form part of contract stipulations. In all four markets, Chicago, Winni Buenos Aires, Liverpool, the grain trade clearing house attend these matters, keeping a registry of the contracts entrusted to i members of the association which carries out the future deli business; non-members are not recognised by these association entitled to obtain this security of position. The penalty for payment of differences at the appointed time is the immediate or purchase, as the case may be, of all contracts standing in the n of the defaulting member in the clearing-house registry. T powers are entrusted by their own members to the Liverpool Trade Assn. to the Chicago Board of Trade, the Winnipeg G Exchange and to the Buenos Aires *Mercado á Término de Cere* respectively.

At Chicago, which is by far the greatest grain futures mar there has always been an avoidance of strictness in procedur regards details, and a resulting immense business in contracts future delivery. The trade is in contracts for future delivery, n wheat for future delivery, and it is not surprising that this busi in contracts should annually reach an aggregate far exceeding U.S. yearly wheat crop. The tenderable descriptions of wheat prise many varieties; in practice, Hard or Red Winter wheat is effective basis. There are certain specified places where deli may be made, and American farmers make great use of the Chi Board of Trade.

At Buenos Aires the Mercado á Término not only registers contracts submitted to the clearing house, but in consideration small fee takes up the contracts with buyer and seller respecti accepting the responsibility towards each party during the curr of the contract. It therefore devolves upon the Mercado to call sufficient margin, and to collect the day-to-day differences. urally the Mercado, in its own interests, keeps strict watch over extent of trading done by its members, and the managers can for increased margins if they are dissatisfied with the posi created. The basis of the wheat contract is the typical wheat of country in sound condition, with the proviso that the natural w attains the requisite standard. Delivery may be made at any way station in the republic, with adjustments for transport expe just as is customary in transactions for immediate delivery.

In Liverpool wheat may be delivered from any of the follo descriptions: American winter or spring Manitoba, Argentin Australian, provided that the sample fulfils the requirement grade.

Maize.—The trade in maize is a very large one, though not e to that in wheat; except in Mediterranean and Danubian land maize consumed in Europe is imported, chiefly from Argentine South Africa. Although the enormous maize crop in the Un States comprises three-fourths of the world's yield of maize, little of it is sent abroad; the United States are not usually seller maize on European markets, though it is generally possible to this grain from them for special requirements, by paying a mod premium. The course of prices for maize is governed by quite d ent factors from those which affect the wheat market. The ex of consumption in some European countries varies greatly different seasons of the year, for droughts may reduce the hay fodder crops and throw the demand on maize, or a season favou to field growth may curtail requirements seriously. The Un States maize crop is chiefly consumed locally, for hog or cattle ing, and most of it is therefore never sold as maize on the market. Any examination of market conditions in the Un States is therefore incomplete unless the meat and provision tr are also studied. Of all the varieties of grain brought from overs maize requires the most care in selection for an ocean voyage. contains a larger percentage of water than does wheat, and is more likely to spoil by heating, if put on board soon after har or in the summer weather of six or eight months later.

Barley.—Most of the oversea trade in barley is in the varie suitable for malting or distilling; compared with wheat or maiz business is small, and in few hands. On the British markets supplies of home-grown barley and those of all kinds of foreign b ley are about equal in quantity, so that brewers and maltsters select the desired quality from either source. The suitability barley for malting is one of the technical studies of the grain tra and a really accurate judgment on a particular sample is not an matter. California and Canada are the main exporters of good m ing barley, but these crops are seldom equal in quality to that England. Russian and Danubian barley are classed much lo down than Canadian, but generally contain a valuable percentag grains fit for malting, separable by machine.

Oats.—The British trade in oats is chiefly in home-grown gra of the country's ordinary requirements over 80% is produced the British Is., and a very large proportion is used locally for dai ing or other cattle food, or horse provender. Imported supplies chiefly from North America.

re.—Finally, rye enters little into trade in Great Britain. The producing countries are Russia, Poland and Germany, whence lies are drawn for Belgium and Holland also. Germany is times a buyer and sometimes a seller, while Russia, with an ense production, did not offer to sell for export in 1925, except ig harvest time. Except under the stimulus of high post-War s the United States has not grown rye at all freely, and now rts but little. (J. H. Hu.)

RAMOPHONE: *see* PHONOGRAPH.

RAND RAPIDS, Mich., U.S.A. (*see* 12.350), had a population 7,634 in 1920 of whom 28,355 were foreign-born, including argest colony in the country from The Netherlands (11,422). 925 the official estimate was 153,698. Annexations of tory in 1915, 1924 and 1925 increased the area to 22 square . While the city kept its title as "the furniture capital of rica," the manufacture of aeroplanes and other essential ucts during the World War led to the permanent expansion further diversification of industries. The commission-manform of government was adopted in 1916. The aggregate e of manufactured products rose from $42,231,100 in 1909 09,135,000 in 1919, and, after a slight decrease in 1921, to ,277,997 in 1923. In 1925 a reconstruction of the city was r way in conformity with a comprehensive city plan, ted in 1922. The public schools were in process of reorsation and a junior college had been added; there was a rvised playground within half a mile of every child's home; iltration plant, built in 1914, had been doubled in size; a ge disposal plant was under construction; several fine hotels, itals and office buildings had been erected. Grand Rapids is nd only to Des Moines in the proportion of homes owned % in 1920). It has a high proportion of children at school, all amount of child labour, a low percentage of illiteracy, general death-rate and a low infant mortality.

RANT, DUNCAN (1885–   ), British painter, was born at iemurchus, Inverness-shire, son of Major Bartle Grant, was educated at St. Paul's School, London. He early ed his remarkable decorative sense, working with Roger at the Omega Workshops, London, and at the same time uced some highly individual painting. His early work ind "The Lemon Gatherers" (1911), now in the Tate Gal- and the "Seated Woman" (1912). Modern French inces, particularly those of Cézanne, made themselves strongly his design and brushwork, as may be seen in the "Tight-Walker" (1918), "Snow Scene" (1921), "The Hammock") and many still-life pictures of this period. Grant, who ne a member of the London Group, also carried out interest- domestic and scenic, decorations and designs for emeries. See Duncan Grant, *A Collection of Plates*, with inction by Roger Fry (1923).

ANVILLE-BARKER, HARLEY GRANVILLE (1877–   ), h playwright, was born in London Nov. 25 1877. At the f 13 he was sent to the Theatre Royal, Margate, then a ination of stock company, theatre and dramatic school. He first appeared in London in the following year, at the Comedy Theatre, under Charles Hawtrey. His first play, written in 1893, was produced by amateurs. From 1895 onwards he acted in a variety of plays, in Shakespeare with Ben Greet, and, with William Poel, in *Richard II.* and Marlowe's *Edward II.* In 1899, his play *The Weather-hen* (written in collaboration with Herbert Thomas) was produced in London. In 1900 he became interested in the newly formed State Society, first as actor, then as producer, and his own play, *The Marrying of Ann Leete*, was produced by the Society in 1901. In 1903 he collaborated with William Archer in the framing of *A Scheme and Estimates for a National Theatre.* In 1904 he joined J. E. Vedrenne in the management of the Court Theatre, London. There, during three years he produced, and at first acted in, a variety of plays by Ibsen, Bernard Shaw, St. John Hankin, John Galsworthy, John Masefield, Maurice Hewlett, Gilbert Murray (translations from Euripides) and his own *The Voysey Inheritance* (1905). In 1906 he published *Prunella* in collaboration with Laurence Housman. A later play, *Waste* (1906), was banned by the Censor, but was privately performed by the Stage Society. *The Madras House* (1909) was produced by the Frohman Repertory Company at the Duke of York's Theatre in 1910, and a revised version of it was revived in 1925. By 1910 he had given up acting, but until 1914 produced plays in London, including two by Shakespeare upon a platform stage with "conventional" decoration. After the War he maintained no active connection with the Theatre. He published various other works, including *The Exemplary Theatre* (1922), dramatic criticism, also translations of several foreign authors. He was public lecturer on the art of the theatre to the University of Liverpool in 1921–2 and he delivered the British Academy Shakespeare lecture in 1925.

GREAT BRITAIN.—The following article is a continuation of the one on the UNITED KINGDOM (*see* 27.598). The change in title is rendered necessary by the altered political status of Ireland. As the change took place during the period under review reference must necessarily be made to Irish affairs, but primarily the article is concerned with Great Britain only (*i.e.*, England with Wales and Scotland), with the lesser islands belonging thereto. It deals with seven matters: (I.) Constitution; (II.) Local Government; (III.) Defence; (IV.) Finance and Banking; (V.) Population; (VI.) Industry and Trade, including agriculture; (VII.) Communications. (*See* also BRITISH EMPIRE; ENGLISH HISTORY; IRELAND, NORTHERN; IRISH FREE STATE; SCOTLAND; WALES.)

I. CONSTITUTION

The years 1910–25 were momentous in the history of the British constitution. They opened with an acute struggle between Lords and Commons which has left a permanent mark on the constitution, in the shape of the Parliament Act. Four years later, with the outbreak of the World War, the country entered on a period of arrested development; a truce was called between the two great political parties and a kind of constitutional moratorium declared in which the operation of the Parliament Act, alike in its application to the duration of Parliament and to the machinery of legislation, was arrested; two statutes, the Welsh Church Act and the Government of Ireland Act, which had been forced through under its automatic action, were suspended.

During the same critical period many rules of the constitution—some statutory, others conventional—were also in abeyance; the re-election of Ministers, on acceptance of an office of profit under the Crown, was one; the cabinet system, in its normal aspect, was another. A kind of super-cabinet, known as the War Cabinet, came into existence, and with it another constitutional novelty, the "Cabinet Secretariat" as a liaison between the Government departments. The liberty of the subject, as the result of that *lex regia* the Defence of the Realm Act and its successors, coupled with a latitude of judicial interpretation which reached its high-water mark in *Rex* v. *Halliday* (*ex parte Zadig*), underwent severe restrictions, and, for the period of the

War and some time beyond it, the country lived under a kind of statutory martial law as unprecedented in its history as the tremendous struggle which necessitated it.

Return to Constitutional Principles.—With the end of the War and the return to normal conditions of existence, constitutional principles reasserted themselves. The courts of law, always jealous of the liberty of the subject, administered severe and salutary checks to the encroachments of the executive, and a series of remarkable judicial decisions, most notably *Chester* v. *Bateson* ([1920] 1 K.B. 829) declared one "D.O.R.A." regulation after another *ultra vires*, while at the same time, in the great constitutional case of *De Keyser's Royal Hotel* v. *the King* ([1920] A.C. 508; [1919] 2 Ch. 197), the courts asserted, if they did not actually extend, the right of the subject to sue the Crown by petition for losses sustained as the result of the exercises of the prerogative in the matter of requisitions. The Defence of the Realm legislation lapsed with the efflux of time, though not the bureaucratic temper to which it ministered, and Parliament, in endowing the executive with somewhat similar powers, in cases of "emergency," under the Emergency Powers Act 1920, was careful to impose the most stringent parliamentary checks upon their exercise. As the result of the De Keyser case, the executive found itself threatened with thousands of claims for compensation, and an Indemnity Act, imposing a time-limit upon such claims and establishing a special procedure for dealing with them, was placed on the Statute Book. The Act had been most jealously scrutinised in its passage through the legislature, and it soon became apparent that Parliament was as little inclined as the judiciary itself to tolerate a continuance of the usurpations of the executive, whose sole justification had been their temporary character. With the fall, in Oct. 1922, of Mr. Lloyd George's Coalition administration, the conventions of the constitution resumed their sway.

Statutory and Other Changes.—It would, however, be a great mistake to regard post-War conditions as testifying to a mere reversion to type. Great statutory changes of a permanent character took place, the most notable of which were the Representation of the People Act 1918, the Parliamentary Qualification of Women Act 1918, and the Sex Disqualification Removal Act of 1919, statutes which, among other things, effected a complete revolution in the civic position of women, removing, as they did, all disqualifications of sex for admission to the franchise, to a seat in the Commons, to service on juries and all public functions. Constitutional changes of equal magnitude were effected by the grant of self-government and Dominion status to Southern Ireland, and by the establishment of representative legislatures and, in some measure, of self-government in India (*see* INDIA). Equally important were the developments in the status of the Overseas Dominions (*see* BRITISH EMPIRE; CANADA, etc.).

Many statutes of considerable constitutional importance, dealing with legal procedure and the administration of justice, were enacted during the years 1920–5, such as the Administration of Justice Acts 1920 and 1925, the Judicature Act 1925, the Criminal Justice Act 1925; and for a long time two such fundamental rights of the subject as procedure by indictment before a grand jury and trial by jury in civil actions at common law were seriously threatened as the result of innovations during the War, which, long after its termination, appeared likely to perpetuate themselves by statute. Another Act of considerable constitutional importance was the British Nationality and Status of Aliens Act 1918, which amended the British Nationality and Status of Aliens Act of 1914. The period under review was also notable for the number of leading cases in constitutional law. Moreover, the growing political consciousness of the working classes had, even before the War, been productive of new conditions, some permanent, others transient. One was the judicial decision known as the Osborne case (*Osborne* v. *Amalgamated Society of Railway Servants* [1909] A.C. 87), resulting in legislation (the Trade Union Act of 1913) for the protection of minorities against the political levy on members of trade unions; another, of which the issue has yet to be seen, was the claim to the active exercise of political power. The policy of direct action,
i.e., the exercise of political pressure upon the Governmen
the day by resort to the weapon of a general strike, was
immediate cause of the action of Parliament in conferring dra
powers on the executive, in case of emergency, to deal by pro
mation with any such threats to the normal economic life of
community. The Govt. exercised this power effectively du
the general strike of May 1926.

The appearance of a minority Government in 1923 raise
constitutional question, long dormant, namely the right
Prime Minister, even though in a minority in the House of C
mons, to ask and receive authority from the King to diss
Parliament. This was a question as to which there could b
real doubt in the minds of those acquainted with constituti
developments since 1858, but none the less it had been the
ject of much dispute when Mr. Ramsay MacDonald accep
office in Jan. 1924. His exercise of this prerogative of the Cr
in the following Oct. may be said to have settled the ques
beyond further dispute.

THE PARLIAMENT ACT AND OTHER MEASURES

Parliament.—The enactment of the Parliament Act in 1
consequent upon the rejection of the Finance Bill by the H
of Lords in the preceding year, limited the authority of
House of Lords. (*See* ENGLISH HISTORY.) It was an emerge
measure, designed to secure the immediate passage into law
Liberal Govt's. legislation. The preamble recognised this to
extent of admitting the necessity of further legislation
substitute for the House of Lords as it at present exists a sec
chamber constituted on a popular instead of a hereditary bas
The implied promise has never been redeemed and the prob
still awaits solution, a solution that has become all the
imperative in view of the vast extension of the franchise effe
by the Act of 1918, the peculiar sensitiveness of post-War gov
ments to public opinion, and the appearance on the polit
scene of a new and powerful party whose avowed object i
revolutionise the economic basis of society by legislation.
did the authors of the Act foresee its constricting effect upon
legislative procedure of the House of Commons itself. The
fusion in which the Government of the day found itself invo
in its financial legislation during the session of 1914 was a
direct consequence of the Parliament Act, for new question
to the legitimacy of tacking non-financial provisions o
finance and revenue bills were raised.

The discretion given to the Speaker under the Act, of deci
whether, in giving or withholding his certificate, a bill c
within the new statutory definition of a money bill, has inve
his ancient office with a judicial authority the particular exe
of which no government can foresee. That authority has hi
to been exercised with the complete independence characteri
of the Speaker's office, but the new powers conferred upon
constituting as they do the sole constitutional safeguard ag
sudden and revolutionary legislation by a party temporaril
a majority in the House, may yet expose the office to poli
capture—to quote the expression of the Trade Union Cong
in Oct. 1924.

The effects of the provisions of the Parliament Act confining
Lords to a suspensory veto in ordinary, as distinct from finan
legislation have been less apparent, as only two measures had
to the end of 1925, been forced through under their operation
they have invested the process of legislation in the Commons w
new rigidity, owing to the necessity of any bill, which is to tak
vantage of the automatic machinery of the Parliament Act, re
ing the character of the same bill in each successive session.
incidental result is the restriction of the right of private member
propose amendments to a government bill, by way of sugges
in its later and automatic stages.

The constitutional crisis of 1910–1 was productive of an
statute, equally novel but much less revolutionary in its charact
the Provisional Collection of Taxes Act. That crisis disclosed
fact, long known to constitutional lawyers, that the budget res
tions under which duties are collected have no legal force, and
the result of the case of *Bowles* v. *the Bank of England* ([1913] 1
57), it was found necessary to enact a statute giving, for the fu
statutory effect, for a limited period of time, to Ways and M
resolutions varying or renewing taxation imposed during the
ceding financial year.

e procedure of the House of Commons during the period under
w has undergone little change and the problem of how to secure
effective control of the House over the estimates remains exact-
ıere it was. It is essentially a problem of parliamentary time,
ı is limited, and the increasing devolution of the legislative func-
of the whole House to standing committees has, with the in-
ing demand for legislation, not solved the question. A new
:ture was made in 1921 by the appointment of an estimates
nittee, but it is confined by its terms of reference to considering
economies can be effected "consistent with policy," which in
ice means that it had no power to deal with questions which
sters choose to regard as outside its jurisdiction. The mere
that its reports are presented after Supply is concluded has de-
d it of any effective voice in the control of expenditure.

interesting departure in the grant of legislative autonomy to
Established Church was effected by the Church of England
nbly Powers Act of 1919. Under the Act powers of legislation
lelegated to the newly constituted National Assembly of the
ch, but subject always to the control of Parliament to be
ised through an "ecclesiastical committee" consisting in equal
bers of members of both Houses. Upon the report of this com-
ee, measures submitted by the Assembly shall, if approved by
olution of both Houses, be presented to His Majesty for the
assent in the same form as a bill. The co-ordinate authority
ed to the House of Lords by this Act, and the legislative inde-
ence secured to members of both Houses, is a noteworthy
rture, but the legislation contemplated does not, of course,
ıke of the character of a government bill. None the less the
s a noteworthy experiment in devolution.

ıe Electorate.—The electoral changes effected by the Repre-
ıtion of the People Act were immense, far surpassing in magni-
the three Reform Acts of the preceding century. Not only did
franchise women and add no less than 13,000,000 electors to
egister, but it also altered and simplified the law of registration,
ted a redistribution of seats, abolished the property qualifica-
and, much more questionably, removed the pauper disqualifica-
At the same time it reduced the qualifications for the exercise
vote, in the case of men of 21 years of age, to the simple require-
of six months residence, or, in the alternative, occupation of
ıess premises, either or both of which might confer the right to
not more than two votes being so conferred. In the case of
en the minimum age is 30, and the basis of qualification has to
ought in the local government franchise. Innumerable other
ges in the machinery of registration and election were effected
he Act. Taken in conjunction with the two Acts previously
ioned its effect is, except in the matter of age, to assimilate the
status of women entirely to that of men. A curious anomaly
s, however, in regard to the position of peeresses. The wife of
er may be elected to the House of Commons, but a peeress in
own right may neither be elected to the Commons nor take her
in the Lords: this was the decision of the Committee of Privileges
iscountess Rhondda's Claim (1922).

ıe Cabinet and the Ministry.—An important, if limited, change in
aw governing the acceptance of office by Ministers was effected
he Election of Ministers Act 1919. Temporary measures had
passed during the War relieving new Ministers on appoint-
from the necessity of seeking re-election; the Act in question
etuated this departure, to the extent of providing that no mem-
on appointment should in future vacate his seat if his acceptance
fice should take place within nine months after the issue of a
lamation summoning a new Parliament. For such a measure
is much to be said, in that it dispenses with the necessity of a
e Ministry, constituted on the resignation of its predecessor
a defeat at the polls, from being subjected to the hazards of a
lection. In 1926 the House of Commons passed a measure
ned to dispense altogether with the necessity of seeking re-elec-
on the acceptance of office.

me of the new ministries created during the War disappeared,
our became permanent—Pensions, Labour, Transport and Air,
ast being responsible for the creation of a new Secretaryship of
. The number of Secretaries of State was further raised to
by the Secretary for Scotland being raised to that dignity.
status of the Dominions overseas has been recognised by the
ion of a Secretaryship of State for the Dominions, but though
ly distinct from the Secretaryship for the Colonies it is united
it in the person of one and the same minister. The Local
ernment Board was reorganised and renamed the Ministry of
th. With the establishment of the Irish Free State the Irish
e was abolished and Irish affairs were transferred to the Colonial
e.

ıe immediate result of the War appeared to be the exaltation of
position of the Prime Minister to a personal ascendancy
npatible with the principles of cabinet government. The insti-
n of the War Cabinet, whereby a small inner council of Minis-
freed from all administrative duties decided all questions of
y—other Ministers being summoned to these deliberations at
discretion of the Prime Minister communicating with them
ugh his own secretariat—could only be justified in time of grave
onal peril. The result was to place in his hands an almost exclu-
power of initiative in Cabinet business, and to undermine the time-honoured principle of the collective responsibility of Ministers. The evil results of this system were manifest long after the War, with effects upon ministerial discipline which were forcibly illustrated by the circumstances attending Mr. Montagu's resignation of the seals as Secretary of State for India.

The disappearance of the War Cabinet, and of the Coalition Govt. of which it had been the offspring, marked a return to normal procedure. In two respects, however, the ascendancy of the Prime Minister would appear to have become permanent: one is that the Permanent Under-Secretary to the Treasury has come to be regarded as the head of the whole civil service, and as an official through whom the Prime Minister may exercise a certain degree of authority over all departments otherwise than through the Ministers in charge of them—possibly an anomalous position; the other is the precedent created by Mr. Asquith when he obtained from the King before the dissolution of 1910 a contingent guarantee that if the Government were successful at the polls such a number of peers would be created as the Prime Minister might think necessary to secure the passage of the Parliament Bill into law.

In one important respect the precedents created by the War Cabinet have left their mark on the constitution. The Cabinet Secretariat, although completely disestablished as an instrument in the hands of the Prime Minister, survives to the extent that minutes of Cabinet proceedings are now kept by a permanent official, who is thus placed in a position of peculiar delicacy if not of peculiar authority. The tradition of "Cabinet secrecy" is to that extent changed. The departure has been much criticised by constitutional purists, but the exact position is obscure.

The Executive.—The outstanding constitutional problem is the continual encroachment of the executive either by using the prerogative or by the presumed exercise of statutory powers, upon the rights and liberties of the subject. The only safeguard against this tendency is the vigilance of Parliament and the independence of the judiciary. The term of office of the Labour Govt. was marked by an attack by the Prime Minister upon the independence of the judiciary in the person of Mr. Justice McCardie, who in the case of *O'Dwyer* v. *Nair* (reported in *The Times*, May 1–June 6 1924) had made certain observations on the attitude of the executive in the case of General Dyer. For this Mr. Justice McCardie was severely criticised in the Commons by Mr. Ramsay MacDonald. On behalf of the judge it was urged that the subject-matter of the judge's remarks was directly raised by the defendant in his plea of justification, and was therefore such as the judge was bound, by the duties of his office, to deal with. The claim put forward by the Prime Minister to the immunity of the executive from judicial criticism was a far-reaching one.

In the *Board of Education* v. *Rice* (1911) the court of appeal and the House of Lords had reminded a department that "it is not an autocrat free to act as it pleases," and had granted rules for the issue of writs of *mandamus* and *certiorari* to control its arbitrary disregard of the law in the exercise of the semi-judicial powers conferred upon it by the Education Act. In *Dyson* v. *the Attorney-General* ([1911] 1 K.B. 410, and [1912] 1 Ch. 158), the Court laid down for the first time that a subject threatened with penalties by the revenue authorities, for non-compliance with interrogatories which were *ultra vires*, had the same right of access to the courts for a declaration of the law against the executive as if the defendant were a private person. These cases are only two out of many. The whole subject is both too large and too technical to be dealt with here, but reform is urgent in two directions: (1) in the assimilation of the rights of the subject to sue the Crown to his rights against a private defendant, (2) in the restoration of both judicial and parliamentary control over the exercise of powers of "subordinate legislation" by Government departments. In one respect there has been a notable reform—namely, the Acquisition of Land (Assessment of Compensation) Act of 1919. This statute provides that where, in the pursuance of any statutory power, land is acquired compulsorily by any government department or local authority, the right of the owner to the assessment of compensation by an independent arbitrator, instead of an official valuer, is to be restored.

The Liberty of the Subject.—For some months during the War the subject was deprived of his rights to trial by jury even in criminal cases, under the Defence of the Realm legislation, but the suspension of this right was short-lived. In the case of the right to a jury in civil actions the situation was much more serious. For seven years, from 1918 to 1925, this right was taken away, and it was the exception, instead of, as hitherto, the rule, that a litigant in a common law action should, on demand, have the right to have his case tried by jury. In the case of *Ford* v. *Blurton* (38 T.L.R. 801) this invasion of an ancient right of the subject was vigorously criticised by the Court of Appeal itself, and the old rule was eventually restored by the Administration of Justice Act of 1925. So too the ancient process of indictment by grand jury was abolished during the War, and for it was substituted, as the accusing authority, the attorney-general. After the War, however, it was restored.

In the case of *R.* (*ex parte O'Brien*) v. *Secretary of State for Home Affairs* ([1923] 2 K.B. 361; A.C. 603), the executive, acting under an order in council which purported to be made under Defence of the Realm legislation, reincarnated as late as 1923 in the form of regulations under the Restoration of Order in Ireland Act, had arrested, with a view to summary deportation to Ireland, an Irishman resident in England; he applied for a writ of *habeas corpus*. The Court of Appeal, in an exhaustive survey of this “ subordinate legislation,” severely criticised the action of the executive, declared the legislation in question *ultra vires* and granted the rule for the issue of the writ. The judgment may be regarded as the classical authority on the scope of *habeas corpus*, and the House of Lords, on appeal, upheld it, at the same time laying down the important principle that their appellate jurisdiction, while always available against a refusal of the writ, does not extend to an appeal against the grant of it—in other words, the right of the subject to summary release, on the determination of an inferior court that he is illegally detained, is established.

II. LOCAL GOVERNMENT

There have been no radical changes in the system of British local government since 1902, when the *ad hoc* education authorities, the school boards, were abolished and their functions transferred to the county and town councils. The hierarchy of local authorities stands in general as it was reorganised in the last two decades of the 19th century. In England and Wales the chief administrative units are counties, county and non-county boroughs, urban and rural districts and parishes.

The county of London has a unique subdivision into the city and the 28 metropolitan boroughs, and there are also in the metropolis and elsewhere a number of joint authorities for special purposes—asylum boards, hospital boards, water boards, burial boards, etc. Scotland has counties, burghs—royal, parliamentary and police—and district committees of the counties in place of the English rural districts. It also has *ad hoc* education authorities and lunacy authorities (district boards of control). The Scottish parish council is the poor law authority, corresponding to the board of guardians in England and Wales. Northern Ireland in the main follows the English system, while in the Irish Free State local government in 1926 was in the melting pot.

The principal reforms of recent years in Great Britain fall under four heads:—

1. The old central authorities, the Local Government Board and the Scottish Local Government Board, were abolished in 1919 and their functions transferred to new creations, the Ministry of Health (for England and Wales) and the Scottish Board of Health;
2. The local government electorate was enlarged by the Representation of the People Act 1918, which extended the vote to women and to certain classes of men hitherto disfranchised;
3. The Rating and Valuation Act 1925 remodelled the machinery of assessment and rating, abolishing the parish overseers and putting their duties in the hands of the county borough and urban and rural district councils;
4. Apart from these specific reforms there has been a general tendency to enlarge the powers of the local authorities, especially in the sphere of the social services. Acts dealing with maternity and child welfare, tuberculosis, venereal diseases, mental deficiency, housing and town planning and education, have all added considerably to the work of the county and town and district councils. At the same time the big towns have grown still bigger, not only by increase of population, but often by extension of their area through the absorption of surrounding districts.

All these developments have revealed grave defects and inconveniences in the system, and have led to a widespread demand for reform. The counties have struggled against the constant encroachments of the county boroughs. The county boroughs and the more important non-county boroughs and urban districts complain, and with reason, that while their functions have been increased they are still unduly controlled and thwarted by the central authority and Parliament. And the absorption of surrounding districts by the big towns and the expansion of public needs have made it more and more difficult to administer effectively such services as transport, water supply, electricity, regional planning, police, etc. This problem is particularly acute in the metropolitan area, and in 1921 a royal commission, under the chairmanship of Viscount Ullswater, was appointed to inquire into the local government of Greater London. The majority of the commission, however, reported unfavourably to substantial change. They contented themselves with rec mending:—

(*a*) Some redistribution of functions inside the administra county;
(*b*) A reduction in the number of the petty local authorities in outer districts;
(*c*) The creation of a statutory advisory committee to assist tral departments in dealing with questions of transport, hou and town planning and main drainage;
(*d*) A scheme for further equalisation of rates within a 10- radius from Charing Cross.

There were two minority reports. The first proposed Greater London should be made into a congeries of county oughs with certain services reserved for administration by a tralised authority. The second recommended a new author popularly elected, for the governance of the whole area. body would be directly responsible for all the large central s ices, and would require to have carefully defined powers co-ordination and supervision of the work of the minor l authorities within its area.

In 1923 another royal commission was appointed, with Earl of Onslow as chairman, to inquire in particular into question of the creation and extension of county boroughs generally into the constitution, areas, functions and mutual lations of all local authorities. It issued a first report in which proposed certain reforms in the machinery for creatin extending county boroughs. The most important of these were

1. All proposals for the constitution of county boroughs shoul made by private bill instead of by provisional order. Proposals the extension of county boroughs should also be made by priv bill, unless the county borough concerned prefers the provisio order procedure and no other local authority concerned objects.
2. The minimum population entitling a borough to apply county borough status should be 75,000, instead of 50,000.

This somewhat conservative report was generally regarde a compromise, designed in the main to ease the friction betw the counties and the towns. In 1926 the commission was paring to deal with the second part of its reforms, which it clear would be considerably affected by the proposed legislat for the break-up of the poor law.

The main problems, therefore, remain unsolved. New win bursting old bottles, and no general agreement has been reac as to the kind of new bottle that is wanted. On two poi however, there is a growing consensus of opinion. A conces must be made to the demand of the great municipalities for centralisation—for local discretion, that is to say, to carry their services or extend their enterprises, including “ munici trading ” schemes, with less interference from Westminster Whitehall. This power they claim in the interest alike of ciency, economy and democracy. On the other hand, there urgent need for a large measure of local centralisation, for constitution of areas and authorities adequate to the performa of services which transcend existing boundaries. The atten may be made to meet this need either

(*a*) By special joint committees of neighbouring local authori for various services such as transport, water supply, electricity so on; or, better, (*b*) by a more drastic reorganisation which wo set up new authorities—“ super-local authorities,” so to speak— these services, as well as for the general supervision of local gove ment throughout their areas.

This was what the second minority report of the Ullswa Commission recommended for London, and it is obviously able of application in other parts of the country. It is in pri ple the line of reform advocated by the “ regionalists.” Regi alism implies a re-organisation in which the whole country wo be divided into a number of regions or provinces, say seven ten or a dozen. These provinces would be natural and not mer artificial units, since different parts of the kingdom have disti ties of common interest, both economic and “ cultural ” (*e* London and the Home Counties; East Anglia; the West Co try; “ Lancastria ”). They would, it is claimed, be the efficient possible units for administering the larger services; on them would be devolved the bulk of the present cen

ority's powers in respect of the supervision of the work of
subordinate, but largely autonomous, local authorities within
region.

ial Purposes (1922); and *English Prisons under Local Govern-*
t (1922); also S. Webb, *Grants in Aid* (1920). (C. M. L.)

III. DEFENCE

1913 an important investigation was held by the Committee
mperial Defence into the principles which govern the defence
Great Britain. For several centuries there had been two
ols of thought. The one, supported by several eminent sol-
s, held that it was necessary to maintain a large army for
nce against invasion. The other, supported by the majority
reat seamen, held the view that it was essential to the eco-
ic life and prosperity of the population to maintain a navy of
cient strength to keep open their sea communications
inst any single foreign navy, or any anti-British combina-
s at sea; and that a fleet, strong enough to achieve that pur-
, would also be in a position to secure the immunity of Brit-
territory from invasion by a foreign army. The invasion
ol met this plea with the argument that the British Fleet
ht be "enticed away" from home waters and the opportu-
then seized to pass a foreign army across the Channel or the
th Sea; and, furthermore, that the larger the home defence
y, the greater the force that must be employed by prospec-
ly hostile foreign countries for effective invasion, and the
er the task of the navy, upon which "freedom to manoeu-
" would thus be conferred during the lengthy process of
mbling the hostile invading army, and transporting it across
intervening sea.

he Question of Invasion.—The invasion school was particu-
active during the years immediately preceding the World
, partly in order to maintain the proposition that the recent-
stablished Territorial Force was required mainly for home
nce, as the terms of enrolment of its members seemed to
cate, and partly in order to support a widespread movement
the introduction of national service for a similar purpose.
controversy came to a head during the years 1913–4, when
Committee of Imperial Defence devoted much time to an
ustive inquiry into the question whether invasion by a
nan army, bearing in mind the size of the German mer-
ile marine, was a more feasible proposition than invasion
French army, which had been ruled out of court some
s before, after a similar investigation by the Committee of
erial Defence, mainly on the plea that French merchant
ping did not suffice for the purpose. The inquiry of 1913–4
ted in the conclusion that invasion, defined as a military
ation on a large scale intended to conquer the country, was
a danger against which it was necessary to make special
ision under the then existing conditions of relative sea-
r, but that the landing of military "raiding forces" upon
sh shores was a possible contingency, against which mili-
forces must be provided.

e situation was thus summed up by the late Sir Julian Cor-
in his official history of the War:—

> e truth is that, with rare and special exceptions, as when the
> y's chief naval force was not based in the Home Area, our
> or Grand Fleet always operated from its home station. Its
> mount duty was to secure the command of Home Waters for
> afety of our coasts and trade . . . . For defence against invasion the system was obviously the only one possible; for control of trade it had been found efficacious, and never more so than proved to be the case in the War of 1914.

In order to draw up definite plans to meet the assumed danger from military raiding forces in time of war, the War Office required definite estimates of the strength of such forces which might succeed in slipping past the naval dispositions. As the strength of these forces must depend upon the number and size of the transporting vessels, this was clearly a question for the Admiralty. The maximum strength agreed upon and accepted by the naval authorities was a military raiding force of 70,000 men, and Sir Julian Corbett has told us that, in naval opinion, no such raid was likely to be attempted except across the North Sea. In the actual event, the coasts of Great Britain were immune from military raiding forces in the World War, although on several occasions definite rumours of their probability caused the authorities to make dispositions for which considerable military forces were employed, at periods when there was an urgent need for their services beyond the seas. For instance, in March 1918, during the time of greatest anxiety for the safety of the British Army on the Western Front, over 41,000 officers and nearly 130,000 other ranks of the army, classed as "fit for general service in any theatre of war in all respects, both as regards training, physique and mental qualifications," were retained in the United Kingdom, while the total strength of the home army, mostly of men in lower categories, reached a total of nearly 2,000,000. In that connection it is also necessary to bear in mind the need to maintain military forces in Great Britain in aid of the civil power, should such a demand arise. The attitude of the population of parts of Ireland, which necessitated the presence in that country of British troops during and after the War provides an example.

There was yet another demand for soldiers in the United Kingdom, to guard, against "evilly-disposed persons," certain vulnerable points of which the loss or destruction would adversely affect the navy, army or air forces. Large numbers of men belonging to the combatant forces, most of them unfit for service abroad, were employed upon work of this nature, besides strong forces of police.

Personnel.—It was also necessary to provide military personnel, especially artillery and engineers, to man the defended ports and naval bases and anchorages, essential for the use of the navy, mercantile marine, and troop transports. The arrangement between the Admiralty and War Office was that the army should be responsible for the fixed defences, guns, forts, electric lights, and so forth and for defence of the land fronts, while the Admiralty provided floating booms as obstructions, and, at some places, submarine mines and the personnel connected therewith. The Admiralty also made arrangements for an examination service, to visit and examine vessels before they were allowed to enter British harbours. A few places, including Scapa Flow in the Orkneys and Cromarty on the east coast of Scotland, received special treatment, the Admiralty providing marines to man the coast batteries and lights. Another important task which fell upon naval personnel was mine sweeping, to keep free of enemy mines the channels leading to and from British ports and anchorages, and there was an additional and only partially foreseen demand for coast watching, in aid of the coastguard. This task was performed to a great extent by volunteer watchers, the boy scouts taking a very active part in the movement.

Coast Defences.—In connection with the general question of fixed coast defences, it is important to realise their limitations. "People often say," wrote Admiral Mahan, "that such and such an island or harbour will give control over such a body of water. It is an utter, deplorable and ruinous mistake." The same author explains further that "control of a maritime region is ensured primarily by a navy, and secondarily by positions, suitably spaced from one another, upon which, as bases, the navy rests, and from which it can exert its strength," and that "in a naval war coast defence is the defensive factor, the navy the offensive. Coast defence, when adequate, assures the naval commander-in-chief that his base of operations—the dockyards and fuel depôts—is secure. It also relieves him and his Government, by the protection of commercial centres, from the necessity of considering them and so leaves the offensive arm perfectly free." On the whole it may be said that British defences adequately performed these functions in the World War, but it is necessary to take note of the point that they did not secure complete immunity for the coastal population; Scarborough, Hartlepool and other places suffered from bombardment by hostile war vessels. Owing to popular demands, these bombardments affected both the movements and the distribution of the sea forces in home waters.

Attacks During the War.—Reviewing the situation, from the defence point of view, of the British Isles in the World War, it is found that naval strength and dispositions secured the country from military invasion or raids, but that some places on the coast, which were considered to be immune under international agreements arrived at in conferences at The Hague, were subjected to bombardment from the sea. The special provision referred to is to be found in Article 25 of the 1907 Hague Conference, which forbids the bombardment, "by any means whatsoever," of undefended towns.

Air Raids.—This is a new feature in warfare, which affects very seriously the defence of Great Britain. The situation was thus described in Aug. 1914:—

> It seems safe to assume that the few hundred aircraft at present at the disposal of any military power would be unable to bring serious pressure to bear upon a hostile nation numbering many millions, spread over wide areas. The moral effect which would be produced by highly mobile aircraft dropping bombs first over one city, and a few minutes afterwards over another city a hundred miles away, would no doubt tend to produce local panics, but, given the right spirit, the material effect would not suffice to produce concerted action amongst the population to force their government to stop the War. (*Sea, Land, and Air Strategy*, 1914.)

This prediction was borne out in the years 1914–8, but considerable damage was suffered in the United Kingdom from air raids. These raids provide the only precedent, derived from actual experience, of the effect of air raids upon the civil population of Great Britain. Putting aside the comparatively trifling loss of naval and military personnel, 619 civilians were killed by aeroplane raids and 498 by air-ship raids, the numbers of injured being 1,650 and 1,236 respectively. Of the total of 1,117 killed, 618 were women and children. Of the 2,986 injured, 1,562 were women and children.

There was no question of pressure being put upon the Government for this reason to end the War without victory. The tendency was to stiffen the determination of the nation to endure all things rather than accept defeat. The deductions to be drawn from the statistics are (1) that airships, owing to their vulnerability, do not afford cause for anxiety, provided that the experience of the World War is studied and adequate defensive measures are adopted; but (2) that the menace from aeroplanes is more serious, though strictly limited in radius. Whether this radius can be increased much beyond the estimate in 1924 of 200–300 m.[1] is a question for the future. The point has been advanced that a reduction of bombing-load, and therefore an increase of fuel-radius, can be effected by substituting lighter and more deadly chemicals and gases for heavy explosive bombs. The increase in range of artillery fire was yet another development which may affect the future defence of Great Britain, for certain ports on the East Coast, and even inland towns, could now be subjected to bombardment from positions on land.

Comparison Between Pre-War and Post-War Conditions.—The situation in 1925, as compared with that in 1910, can thus be summarised. As long as a sufficiently strong navy is maintained, immunity from invading armies can be ensured in the future, as it has been in the past. The menace from the air would depend upon the country with which Great Britain might be engaged in hostilities, and would not be very serious except in a war against countries within the radius of action of bombing aeroplanes starting in large numbers from land aerodromes. Long-range bombardments of certain places near the East Coast co
be effected by heavy ordnance in similar localities. The na
and the merchant shipping under its protection, would be o
to air attack when carrying out their task of keeping up the tra
port over the high seas of essential goods to and from Gr
Britain; air forces, under naval control, would be essential
meet this menace. The general effect of the air menace, a
factor in the problem of British defence, may be gathered fr
the attitude of successive British Govts., which have foun
necessary to adopt a "one-power" standard of strength in
air, to establish a separate air force controlled by an Air Minis
and to appoint an air officer as commander-in-chief of the ho
air forces, a step which, in time of peace, has been conside
to be against the best interests of the nation if applied to
military forces.

Irish Free State.—The grant of self-government to the Irish F
State has a considerable effect upon the defence of Great Brit
This quasi-political question cannot be dealt with exhaustively
an article devoted exclusively to defence. Its main features are
the control by the Free State Govt. over its own forces; (2)
loss of a large number of recruits, of a wide area of recruitm
for the British Army, and of important training grounds; (3)
prospect for Great Britain in future emergencies of having a frien
population in southern Ireland, in place of one bitterly hostile
requiring the presence of a strong British garrison; (4) the contin
provision of a small nucleus of British troops in certain defen
ports, and also the question of the ability, if not the eagerness
the Irish of the Free State to deny their harbours to war ves
hostile to Britain, and to provide an organisation for coast-watch
to ascertain and report, as was done by British coastguards
1914–8, the movements of such vessels within sight of the I
coast. Unless these services are adequately fulfilled, the establi
ment of a Free State in Ireland would, in a grave emergency such
the World War, affect adversely the defence of Great Britain.

Conclusion.—In conclusion, we have noted that the princi
change between 1910 and 1925 in the defence of Great Brit
has entailed the provision of a large localised Air Force, control
by an Air Ministry and an air officer commanding-in-chief,
addition to the air forces needed to accompany British fle
and armies upon their world-wide mission. Nevertheless,
burden of home defence may bear less heavily upon the Brit
people than their responsibility for defending people of ot
races and nationalities, spread over both hemispheres (*see*
FORCES; ARMY; COAST DEFENCE; NAVY; etc.).

IV. FINANCE AND BANKING

The years immediately preceding 1914 were a period of rapi
growing expenditure, due (1) to the increase of the navy a
(2) to social reforms.

National Expenditure

	1908–9	1914–5 (Estimates)
Debt	£28,000,000	£23,500,000
Army	26,840,000	28,885,000
Navy	32,188,000	51,550,000
Old Age Pensions	..	12,710,000
Insurance of Working Classes	..	9,312,000
Other Expenditure	65,264,000	81,064,000
Total	£152,292,000	£207,021,000

The growth of £15,800,000 in other expenditure was larg
natural expansion, *e.g.*, an increase of £8,000,000 in the p
office. The increase in total expenditure (after allowing for t
reduction of £4,500,000 in the debt charge) was £59,000,000,
which defence contributed £21,400,000 and social legislat
£22,000,000.

So great an increase in expenditure had naturally involv
additional taxation. The extensive measures of new taxati
imposed by Mr. Lloyd George's budget of 1909 (which was
jected by the House of Lords and was only passed after a gene

---

[1] Report of Sub-Committee of Committee of Imperial Defence (Cmd. 2029, 1924).

ction) provided the greater part of what was required. The ture in that budget of greatest permanent importance was the titution of a supertax, that is to say an additional income tax large incomes. Incomes above £5,000 were taxed at 6d. in the ınd on the excess over £3,000. At the same time the rate of ome tax on unearned income was increased from 1s. to 1s. 2d. er the great effort of 1909 the natural expansion of revenue ficed to cover expenditure till 1914. In that year further taxan became necessary, and the budget as finally adopted (before War crisis) provided for an increase in estate duties, a rise in income tax on unearned incomes from 1s. 2d. to 1s. 3d. (the ned still remaining at 9d.), and an important extension of supertax. Supertax was applied to all incomes over £3,000, l was more elaborately graduated (the rate on the excess of income over £8,000 was 1s. 4d. in the pound). The estimated ld for a full year was thereby raised from £3,300,000 to 770,000 (*see* Income Tax).

The War Period.—From the beginning of the War in Aug. 4 it became impossible to dissociate the budget position from state of credit generally. In the first place, the Government had to come to the assistance of the financial world and pport credit through the initial crisis. Secondly, expenditure the War soon grew to such dimensions as to put an almost bearable strain on the financial fabric of the country.

The outbreak of the War threw first the stock exchanges and n the foreign bill markets of the world, but above all of Lon, into utter disorder. The machinery of remittance to Lon broke down almost completely and the London accepting ıses found themselves faced with bankruptcy. The Government was forced to step in and to proclaim a moratorium for ots, statutory power was taken for the Treasury to issue legal ıder currency notes for £1 and 10s. and the Government guarteed advances by the Bank of England to acceptors to pay pre-moratorium bills (*see* Stock Exchange).

War Borrowing and Inflation

It was in the midst of this state of confusion that the early stages the War were financed. For the initial expenses, advances of .720,000 were obtained from the Bank of England on "Ways Means" (*i.e.*, under the powers annually conferred by the Conidated Fund Act and Appropriation Act). The War was cost about £1,000,000 a day. There followed half-a-dozen issues Treasury bills of £15,000,000 at a time. In Nov. 1914 addinal taxation was imposed and a loan of £350,000,000 (3½% 95, redeemable 1925–8) was decided on. By that time serious soundness was already developing in the situation. The issue £90,000,000 of Treasury bills did not in itself overstrain the rket. But the advances made by the Bank of England for the -moratorium bills, with its advances to the Government and ge imports of gold, destroyed the Bank's power of controlling money market. Bank Rate had been reduced to 5% on the pening of the banks on Aug. 7, but in Sept. it ceased be effective and the market rate fell to 3%. In Nov. it below 3. Part of the 3½% loan was taken by the banks, and any case the loan was not applied to strengthen the position the Bank of England. In Feb. 1915 the market rate of disınt fell below 2%. The private deposits at the Bank of England exceeded £130,000,000.

At last, in March 1915, severe measures were taken to counact the growing inflation, which had already caused a considble rise of prices. The Bank of England came into the Money rket as a borrower at call on the same footing as the discount uses, and lent the proceeds to the Government. The money s accumulated in balances, and public deposits at the Bank e from £27,000,000 at the end of Feb. to £114,000,000 at end of March and other deposits fell to £90,000,000. On ril 13 a new departure was made, in that Treasury bills in united quantities were placed continuously on sale at fixed rates interest to all comers. But the rates were still low (2¾% for 3 nths, 3⅝% for 6 months, 3¾% for longer maturities). Public posits rose to £130,000,000 and more. It was the Treasury bill e, and not bank rate, which regulated the money market.

By that time the cost of the War had risen to £3,000,000 a day and exceeded one-third of the national income (even if this be assumed to have risen in proportion to prices, which were 25% higher than in 1913). This outlay (after deducting a modest contribution from the tax revenue) far exceeded the amount that the people could save. But inflation only made the situation worse. That the cost of the War was itself swollen by the high prices was the least part of the evil. Easy credit makes trade profitable, because it encourages buying and consumption. It directs savings away from gilt-edged investments into trade. In 1915 conditions were extremely abnormal, but, for all that, this tendency was at work. Lavish expenditure by the public on consumable goods was competing with the Government, not only for the investment of the available savings, but for the employment of the available labour and productive power. Inflation, once started, continued throughout the War and for some time afterwards and only spasmodic and half-hearted steps were taken to check it till 1920, when prices had risen to three times the pre-War level.

Mr. McKenna, in June 1915, brought out the second war loan (4½% at par, redeemable 1925–45). It was for no specified total amount. The banks again undertook to subscribe for a very large amount, but the loan was planned much more for the ordinary investor and less for the money market than the 3½% loan of November. It also remained open longer, and there was more propaganda. Subscribers were given the right to convert their holdings into any future long-dated war loan. Holders of 3½ per cents or of consols were allowed to convert these securities into the new loan if they subscribed in addition a certain amount of cash to it. The loan yielded £587,000,000 of cash, but £200,000,000 came from the banks, and the balance was but a modest contribution from genuine savings towards the growing expense of the War.

While the loan was still being subscribed, ominous signs of weakness began to appear. The rise of prices was resumed. The exchange on New York fell below $4.80 to the £1 sterling; at the end of Aug. it dropped to $4.50. The Government sought a remedy in the sale of gold and securities in New York. Gold received in 1914 and deposited at Ottawa, gold displaced from circulation by currency notes, gold extracted from the precious reserves of France and Russia, all were drawn upon. The total net imports of gold into the U.S. in 1915 were $420,000,000, of which two-thirds came in the second half of the year. The British Govt. collected American securities from British holders, and either sold them or pledged them in America. There was also direct borrowing in America, starting with the Anglo-French loan of Oct. 1915 ($500,000,000, five-year 5 per cents at 98).

By means of these resources it became possible to "peg" the exchange at 4·76½. That measure made inflation more ruinous to the country than before. Inflation creates an excess of imports, which can be corrected, if the gold standard is abandoned, by an adverse movement in the exchanges. If the Government prevents that adverse movement by undertaking to sell foreign currencies to all comers, the excess of imports continues, and the Government has to pay for it. There were obstacles to imports in 1916 (especially lack of shipping), but the burden assumed by the Government was still a formidable one. The British Govt. also had to supply the necessary resources for pegging the French franc.

What was needed above all was the cessation of inflationary finance. The 4½% war loan had been of some assistance. In Aug. 1915 the lowest rate for Treasury bills was fixed at 4½%. In Sept. new taxation was imposed calculated to yield over £100,000,000 in a complete year, and in May 1916 further increases brought the revenue for the year 1916–7 above £500,000,000. But the cost of the War had risen to £4,500,000 a day and the rise of prices above the peace-time level exceeded 50%. In Dec. 1915 five-year 5% Exchequer bonds were put continuously on sale from day to day, but yet in March 1916 the floating debt (Treasury Bills and Ways and Means Advances) was almost £600,000,000.

In July 1916 Bank Rate was raised to 6%, and the Treasury bill rate to 5½. The effect of Bank rate on borrowing depends on the profits of trade; 6% is by normal standards a very high rate, but in face of the profits promised by an orgy of inflation it counts as low. At any rate it was not high enough to have much effect in 1916. The sale of five-year Exchequer bonds (raised to 6% in Oct. 1916) continued till Jan. 1917. Mr. Bonar Law, who had become Chancellor of the Exchequer in Dec. 1916, then decided on a third World War loan.

This took two forms: 5 per cents at 95 (redeemable 1929–47) and income-tax free 4 per cents at par (redeemable 1929–42). A "Depreciation Fund," equal to ⅛% per month, was to be applied to buying up stock in the market whenever it was below the issue price. The amount asked for was unlimited, and the zeal of the public was stimulated by intensive propaganda. It was wisely decided to ask for no direct subscriptions from the banks. The cash raised was £816,000,000, and Treasury Bills subscribed amounted to £124,000,000. In addition holders of 4½% war loan and of the Exchequer bonds since issued were entitled to convert into the new stock. The total amount created was £2,067,000,000 of 5 per cents and £52,000,000 of 4 per cents.

Even after this great effort the floating debt at the end of the financial year (March 31 1917) amounted to £680,000,000. Prices were almost double the peace-time level. Growing difficulty was experienced in providing resources for the support of the American exchange. The vast quantities of gold sent to the United States (whose net imports of gold from Jan. 1915 to March 1917 amounted to $1,192,000,000) not only paid for goods, but brought about a credit inflation and rise of prices there. Indeed otherwise the discrepancy in value between the pound and the dollar would have been far too great for any pegging operation to be feasible. But the effect of the credit inflation in America was to make borrowing there more difficult in face of the insistent demands of trade for all available supplies of capital. It was found possible to raise loans of $250,000,000 in Aug. 1916, $300,000,000 in Oct. 1916 and $250,000,000 in Jan. 1917, but the market was growing more and more reluctant.

All such anxieties were dispelled by the entry of the United States into the War in April 1917. Thenceforward the necessary resources both for supporting the exchange and for buying food and materials were advanced to the British and Allied Governments by the American Govt. itself. The British Govt. continued to provide funds to enable the Allies to buy goods in England, but the amount lent was about equal to the amount borrowed from the American Government. Inflation in the United States was accelerated and the export of gold thence was prohibited. The price index rose from 162 in March 1917 (100 being the average of 1913) to 203 in Nov. 1918. The English price index in Nov. 1918 was 229. The cost of the War to the British Exchequer had risen to £7,000,000 a day. Bank Rate had been reduced to 5½% on Jan. 18 and to 5% on April 5 1917.

After the 5% war loan, borrowing was effected through Exchequer bonds, re-christened in Sept. 1917 "National War Bonds." They were 5 per cents, but were repayable on maturity at a premium (2% on the 5-year bonds, 3% on the 7-year and 5% on the 10-year), and were convertible at the holder's option into 5% war loan at 95 (*i.e*, a £100 bond would buy £105 5s. 3d. of war loan). There were also income-tax free 4% 10-year bonds, repayable at par, and convertible into 4% war loan. National War Bonds were continuously on offer till the Armistice and thereafter till May 1919 (those issued after Jan. 1919 having no conversion rights).

Much attention had been given to the attraction of savings from the working classes. Special facilities were given for the purchase of the 4½% war loan of 1915 in bonds of small denominations. In 1916 a special issue of War Savings Certificates was started. The subscriber paid 15s. 6d. for a certificate entitling him to £1 after five years, and he could obtain repayment at any time at the sacrifice of a part of the accumulated interest. The interest accumulating, and not payable periodically, was not liable to income tax, and to prevent too extensive an evasion of income tax by well-to-do holders, the amount of certificates which could be held by any one person was limited to £500.

On March 31 1919 the National Debt amounted to £7,481,000,000, an increase of £6,775,000,000 since March 31 1914. The external debt was £1,365,000,000, or, if certain items which could be set off against debts due to the British Govt. from Canada, France, Italy and Russia be omitted, £1,179,000,000. The internal floating debt was £1,339,000,000[1] including £455,000,000 of Ways and Means Advances; the latter included su lent by Government Departments (partly from the Curre Notes Account, partly from trading accounts and many ot sources). But a large part was money borrowed at call thro the Bank of England from the Money Market, extra inter being paid for foreign-owned balances.

War Taxation.—Though there were heavy increases in in rect taxation, far the greater part of the war taxation was dire as the following comparison shows:—

Taxation in Peace and War

Source of Revenue	1914–5 (Peace Estimate)	1918–9
	£ · millions	£ millions
Customs and Excise	75·3	162·2
Income Tax	48·1	255·6
Supertax	5·8	35·6
Excess Profits Duty	. .	285·0
Other Direct Taxes	42·1	45·9
Other Revenue	35·8	104·7
	207·1	889·0

The rate of income tax had been raised to 2s. 6d. in 1915–6 a to 5s. in 1916–7. In 1918–9 the rate was raised to 6s.; the effect this last increase was not fully seen till 1919–20, when the yield £317,000,000. Supertax rates had likewise been raised, and the hi est zones of income paid 4s. 6d. The biggest tax of all was the Exc Profits Duty, which had been imposed by Mr. McKenna in Se 1915. This was a tax on the excess of the profits made by any fi or company in the year of assessment over the annual profits ma before the War (computed in the case of a business established sin the outbreak of war from its capital). Administratively it was off-shoot of the income tax, for the income tax assessments disclos both the current profits of a business and its pre-War standa The rate of tax was at first 50%, and was raised in 1916 to 60% a in 1917 to 80%. Excess Profits Duty was a powerful correcti of inflation. It provided £645,000,000 revenue in the three yea 1916–7 to 1918–9, and £540,000,000 more in the difficult years t followed. It diminished the evil tendency of inflation to accentua the inequalities of wealth. By it the extravagant profits whi made trading enterprises unduly attractive to capitalists, in co petition with the needs of the Government, were materially reduce Excess profits duty was never anything but a makeshift. It was f of anomalies and minor injustices. But these, in the emergency the time, were as dust in the balance compared to its advantages.

The indirect taxes imposed included import duties on motor-ca clocks and watches, musical instruments and cinema films—officia known as the new import duties, but more commonly called t McKenna duties. They are noteworthy as being the first protecti duties imposed since the days of the Peelites.[2] They were ostensil intended to support the exchange and to economise tonnage.

The Cost of the War

An exact calculation of the cost of the War to Great Brita would be impossible, and what follows can be regarded as more than an approximation. The day after the declaration war with Germany the Government obtained from Parliame a vote of credit of £100,000,000, for "expenses, beyond tho provided for in the ordinary grants of Parliament, arising out the existence of a state of war." Certain services, such as nav and military operations, maintenance of trade, relief of distres were specifically mentioned, but the total was not divided in subheads like an ordinary vote. Till March 1919 the cost of t War was met from successive votes of credit. The total audite expenditure from votes of credit was £8,417,000,000. T table on the opposite page shows the principal details.

Civil Departments drew on votes of credit for any expenditure excess of their own votes, attributable to the War. Some items met (*e.g.*, for cost of living bonus to civil servants) were not part the cost of the War. But on the other hand the ordinary votes bo many war charges such as the civil pay of staff absent on milita service, or the cost of administrative work arising out of the Wa The total includes £1,665,000,000 of loans to Allies and Dominion These were an immediate burden when advanced, but the ultima burden is only such part as is never repaid. The immediate bu den was relieved by the advances received from the Canadian a American governments.

---

[1] Exclusive of Treasury bills amounting to £73,000,000, included in external debt (see Cd. 1648).

[2] Except the ephemeral corn duty of 1902.

Receipts[1]	254·4	265·7	110·8	43·4	29·7
	486·7	(8·0)[2]	38·6	16·2	(14·1)[2]

[1] Mainly sales of war stocks, ships, etc., but exclusive of repara- ns.

[2] Excess of receipts over expenditure.

A further net sum of £22,250,000 was provided through the il contingencies fund (advances, 1919–20, £64,500,000; re- yments 1919–20 to 1921–2 £42,250,000). The total net war penditure is thus (in £ millions):—

Total War Expenditure

	British Expenditure	Loans to Allies, etc.	Total
Votes of Credit	6,084	1,665	7,749
Subsequent Years	376	166	542
	6,460	1,831	8,291

Advances *from* Allies were:—	
United States	865
Canada	184
France, Russia and Italy (gold)	136
	1,185
Voluntary contributions from India and Colonies (principal only) up to 1923	90
	1,275

This may be regarded as reducing the net "immediate burden" of advances to Allies to £556,000,000. The burden of War pensions, actuarially capitalised at some date in the midst of the War, may be put at £1,000,000,000.

Finance After the War

In 1919 the tremendous overstrain of the War period was still making itself felt in the direction of inflation. The most obvious symptoms of weakness were in the floating debt and the external debt (see above). The shortage of tax-revenue and genuine savings, as compared with the expenditure to be met, was made good partly by drawing on foreign resources, partly by bank credits. Practically, with the cessation of advances from the American Govt., foreign resources ceased to be available. Bank credits meant the creation of the means of payment out of nothing—pure inflation. Excessive Government borrowing seemed so entirely adequate an explanation of the growing inflation that a more insidious cause was hardly taken into account. Bank rate had remained at 5%, but had not been made effective. The Treasury bill rate, which governed the market, had been reduced since Feb. 1918 to 3½%. Under war conditions the effect of cheap commercial borrowing in stimulating business was undoubtedly much diminished though not entirely avoided. With the return of peace its full effect would be felt.

The committee on currency and foreign exchanges after the War, presided over by Lord Cunliffe, had presented a grave and authoritative report in Aug. 1918. The report urged the cessation of Government borrowing, but also the use of a high Bank rate to protect the gold reserves. The foundation of all their recommendations was that "under an effective gold standard all export demands for gold must be freely met." "The conditions necessary to the maintenance of an effective gold standard in this country no longer exist, and it is imperative that they should be restored without delay." Unless the remedies approved by experience were applied, "there will be very grave danger of a credit expansion in this country and a foreign drain of gold, which might jeopardise the convertibility of our note issue." The Committee condemned proposals for "a liberal supply of money at low rates," based on a further growth of the note issue, because "in the result the gold standard will be threatened with destruction through the loss of all our gold."

In spite of these wise and emphatic recommendations, the gold standard was abandoned without an effort, as soon as the arrangement for supporting the New York exchange with American credits was brought to an end. A regulation under the Defence of the Realm Act, replaced in 1920 by the Gold and Silver (Export Control) Act, prohibited the export of gold (March 1919). The régime of cheap money continued. Burdened with heavy war commitments the Budget for 1919–20 brought the prospect of a heavy deficit. In June a new 4% loan was offered for subscription in two forms, the funding Loan, at 80, redeemable 1960–90; and the Victory Bonds, at 85, repayable by annual drawings at 100.

During the War the issue of loans at a considerable discount had been avoided, the lowest price of issue being 95. This was a favourable contrast to the policy during the Napoleonic wars, which swelled the nominal amount of the debt and diminished the effectiveness of the big conversion operations of the 19th century. The Funding Loan represented a change in that respect. It secured the investor against the reduction of his interest after 1960 unless the market rate of interest had fallen by then below 4%. That is a very slight advantage to the investor, and any difference that it made in the price of the loan would not go far to compensate the Government for the loss of what might be a valuable option in the future.

The twin loans yielded £475,000,000, but £92,000,000 had been subscribed by banks, so that the real contribution towards sound finance was only £383,000,000. Moreover, the well established but deceptive city tradition of fertilising a loan with cheap money had been followed. The sale of Treasury bills had been absolutely suspended, and the Government had borrowed at a low rate from the money market and so far as necessary from the Bank of England. The inflationary tendency, already serious, was accentuated. The sale of Treasury bills was resumed on July 14. In Oct. came a change; the rate for three months bills was raised from 3½% to 4½%—the first step towards a restriction of credit. In Nov. the rate was raised to 5½% and Bank Rate to 6%. In Dec., pursuant to a recommendation of the Cunliffe Committee, a limit was imposed upon the currency note issue. A Treasury Minute of Dec. 15 1919 (a purely administrative instrument without statutory validity) prescribed that the fiduciary issue of currency notes (those uncovered by gold or Bank of England notes) in any year should not exceed the maximum fiduciary issue recorded in the preceding year. The actual maximum recorded for 1919 was £320,600,000, and accordingly this became the prescribed maximum for 1920. Under this rule the limit can decrease but cannot increase. The limit for 1926 was £247,900,000.

Inflation in Great Britain works through bank credits, but a limit on the supply of legal tender money, if really meant to be effective, was bound to react on the creation of credit. Nevertheless in the opening months of 1920 inflation continued unabated. The price level (*Statist* index, 1913 being 100) rose from 217 in April 1919 to 313 in April 1920. The American exchange fell one-third below par. In April 1920 the sales of Treasury bills at the fixed rate of 5½% fell off, and £55,000,000 had to be borrowed from the Bank of England on Ways and Means. An abyss of inflation seemed to be opening. The Treasury bill rate was thereupon put up to 6½%, and Bank Rate to 7% (April 15).

The next week Mr. Austen Chamberlain introduced the Budget for 1920–1. Inflation was swelling the revenue from the heavy taxes already in existence, but fresh taxation was nevertheless imposed. A tax revenue exceeding £1,000,000,000, in addition to enormous receipts from liquidation, was budgeted for, and the estimated surplus was £234,000,000. The severe régime of high discount rates and no Government borrowing, recommended by the Cunliffe Committee, was being applied. But after a year of unconscionable inflation, a stronger dose was needed than they ever contemplated, and produced results which they never thought of. A year of 7% Bank Rate caused a tremendous collapse of prices, while the exchange was little improved (*see* CURRENCY), and the gold standard was not restored.

The peril of inflation had vanished. It was excessive deflation that was now the trouble. But a contraction of credit, while it brings depression, bankruptcy and unemployment, nevertheless, after the first passing phase of stringency, causes a rise in the prices of fixed-interest securities and favours funding operations, just because it diminishes the profits of production and trade.

When the budget for 1921–2 was introduced in April 1921, little progress had been made with the floating debt, which still amounted to £1,243,000,000. The loan issues of 1919, together with an issue of 5¾% Exchequer bonds in Feb. 1920, had been mostly used up in meeting a deficit of £326,000,000 for 1919–20 and a large amount of maturing bonds. The surplus of £230,000,000 for 1920–1 had been needed partly to pay off external debt (including $250,000,000 of the Anglo-French loan of 1915 maturing in Oct. 1920), and partly to pay off bonds. Further heavy maturities were in prospect. By April 1922, £138,000,000 of Exchequer bonds would have to be met, and between Oct. 1922 and Feb. 1924 the 5-year National War Bonds, amounting to £574,000,000. Certain securities also had the privilege of being used in payment of Death Duties and Excess Profits Duty. The total amount so used had been averaging £70,000,000 a year. The Depreciation Fund on the War Loan of 1917 required over £30,000,000. All these obligations had to be met if the floating debt was to be prevented from increasing.

In the Budget statement in April 1921 was announced the issue of a new 3½% Conversion Loan. It was to be a funded stock like Consols, being redeemable only at the option of the Government (after 1961), and not at any fixed due date. A sinking fund of 2% per annum on the amount outstanding was to be applied so long as the price was below 90. Cash subscriptions were not asked for, the loan being destined only to be exchanged for the 5-year and 7-year National War Bonds. At that time gilt-edged stocks had not recovered far from the lowest levels of 1920. The 4% funding loan which had fallen to 66 in Dec. 1920, stood at 71. The 5% War Lo had risen from 81½ to 88. The National War Bonds (carrying premium on redemption) were slightly below par. From £160 £163 of 3½% Conversion Loan was offered to the holder of £100 National War Bonds. The stockholder was secured a return about 5⅔% on his money, and the interest could not be reduced fore 1961, and even then only if the Government was able to borr at less than 3½%. By good fortune the loan was a failure. O £164,000,000 of National War Bonds were converted, out £630,000,000 to which the offer applied, but even so the increase the nominal amount of the debt was about £100,000,000.

A year later, still months before the earliest maturities National War Bonds, the situation had been transformed by t trade depression. The 4% Funding Loan at 88½, and the 5 War Loan at 99 were well above their issue prices. The Conve sion Loan, which had been offered in April 1921 on terms co responding to a price of 62, had risen to 77¾. Treasury Bon to yield 5½%, and then, as the market improved, 5% had be sold to an amount exceeding £400,000,000. In 1922 a furth batch of £70,500,000 of National War Bonds were convert into 3½% Conversion Loan on the basis of a price of about When the bonds were above par it ceased to be profitable use them in payment of duties. And now that the 5% War Lo was well above the issue price, the option attaching to Natio War Bonds of converting into it at the issue price became profi able, and in the three years 1922–5, £251,000,000 were so co verted. No difficulty was found in raising the money to pay £100,000,000 in cash in the same period, and in addition t floating debt was reduced from £1,243,000,000 in March 192 to £742,000,000 in March 1925 (inclusive of £166,500,000 advances from Public Departments).

In April 1921 the pre-War system of selling Treasury bil by public tender was reverted to. The change was an importa one, because it meant that in respect of the discount rate t Treasury followed the market instead of leading it. So long the Treasury sold all the bills that the market would buy at prescribed rate and no more, the Bank of England was boun to lend to the Treasury if the sales of the bills did not produ enough. A Bank Rate appreciably above the Treasury bill ra could not be made effective. A Bank Rate below the Treasu bill rate would be equally unworkable. In fact the Treasu had usurped the place of the Bank as regulator of credit. S long as bills are issued by tender in just sufficient amounts meet the needs of the Treasury, the Bank of England can di charge its responsibilities undisturbed.

In 1924 a new form of Conversion Loan was created, a 4½ security redeemable in 1940–4, in order to make a beginning wit the conversion of the great 5% War Loan. The Government has t option of repaying that loan at par at any date after 1929. Th amount involved is enormous. Conversions of National War Bond had raised the total in April 1924 to £2,100,000,000. Difficult might be experienced, even in a favourable market, in dealing wit so great a mass of stock, if notice were given in respect of the whol in or after 1929, and there may therefore be advantages in converti moderate portions at a time by offering suitable terms to the holder The amount converted into 4½% was £148,000,000.

American Debt.—The net external debt had been reduced fro £1,179,000,000 in March 1919 to £948,000,000 in March 1922, o which £856,000,000 represented the debt to the American Govern ment. But these figures exclude the interest on the American deb which the American Government had spontaneously suspended i 1919 and which had been accumulating ever since. Towards th end of 1922 it was decided to negotiate with the American Govt for the settlement of the arrangements for paying off the debt. sum of $100,000,000 was paid on account and in March 1923 a agreement was negotiated by Mr. Baldwin, the Chancellor of th Exchequer, who with Mr. Norman, Governor of the Bank of England, visited the United States for the purpose.

The loan had been till then in the form of an obligation payabl "on demand" and yielding interest at 5%. The agreement reduce the suspended interest to 4¼%, and fixed the future interest at 3 for 10 years and thereafter at 3½. The capital of the debt (includin past interest) was rounded down by a small cash payment t $4,600,000,000, and was to be paid off by instalments in 62 years starting at ½% ($23,000,000) and rising gradually so as to keep the annual obligation for interest and principal together approximately fixed at about $161,000,000 for 10 years and $184,000,000 thereafter. Great Britain has the option of paying the debt either in "U.S. gold coin of the present standard of weight and fineness" or in gold bullion or in bonds of the U.S., and may postpone the ment of half of any instalment of interest. There was in addition ebt of $61,000,000, being the balance of the advances of silver de for the benefit of India under the Pittman Act of 1918. This was paid off in 1923 in cash. (*See* Debts, Inter-Allied.)

inking Fund.—The sinking fund in operation at the beging of the War (a fixed debt charge of £23,500,000 inclusive interest) had become obsolete. Surpluses of revenue over enditure were legally applicable to the redemption of debt e "old sinking fund"), and under the Finance Act of 1920 rplus could be so applied as it accrued, instead of being acnulated in Exchequer balances till the end of the year. The umulation of a surplus of £200,000,000 like that of 1920–1 ld have been an absurdity. The Finance Act of 1923 reled the fixed debt charge arrangement, and established a sinking fund. A sum of £40,000,000 was to be included in expenditure of the year for the redemption of debt in 1923–4, ,000,000 in 1924–5 and £50,000,000 in 1925–6 and subsent years. With the fixed debt charge the saving of interest t to increase gradually the amount applicable to debt renption. Under the sinking fund of 1923 it goes in diminution xpenditure, the sum applicable to debt redemption remainat £50,000,000. Surpluses, however, remain, as before, licable to debt redemption. Realised surpluses have been follows (in £ millions):—

920–1	1921–2	1922–3	1923–4	1924–5
230·6	45·7	101·5	48·3	3·6

epayments of principal of War advances to Dominions and relief loans are paid to the National Debt Commissioners for t redemption, without appearing in the Exchequer account.

ost-War Taxation.—The year 1919–20 was financially a War with a heavy deficit. The Excess Profits duty was reduced from to 40%, but at the same time heavy additional duties were placed beer and spirits, calculated to produce an additional revenue eeding £50,000,000, in a full year. The budget of that year (Mr. amberlain's) is noteworthy for the introduction of preferences in our of products of the British Empire. Protective duties were not oduced for the purpose, but the preference was grafted on the enue duties already in existence (sugar, tobacco, tea, etc.) The r 1920–1 saw the end of War deficits. Nevertheless big additions e made to taxation, further increases on beer and spirits, an inased super-tax, a new tax on the profits of limited companies, a rise in ess Profits duty to 60 per cent. On the other hand an important plification of the system of Income Tax abatements involved a of revenue in a full year of about £30,000,000 (at 6s. in the nd). This year saw tax revenue at its maximum, £1,031,700,000. he years 1921–2 to 1924–5 were years of steady remissions of ation. Excess Profits duty was repealed (1921). Corporation fits Tax was first halved (1923), then repealed (1924). Income was reduced from 6s. to 5s. (1922), to 4s. 6d. (1923) and to 4s. 25). The duties on beer (1923), sugar (1924) and tea (1924) were uced. The "McKenna" duties were repealed by Mr. Snowden 1924, but reimposed by Mr. Churchill in 1925. The Safeguarding ndustries Act, 1925, imposed a number of protective duties.

Analysis of Expenditure

	(£ millions)					
	1919–20	1920–1	1921–2	1922–3	1923–4	1924–5
Ordinary						
Debt	332	350	332	324	347	357
Defence	160	160	155	120	113	111

Education	41	56	61	49	48	49
Old age pensions	19	25	26	22	23	25
Health and labour ministries	19	28	38	31	32	34
Other	123	157	196	135	148	146
Total ordinary	793	882	904	762	784	792
Exceptional						
Bread subsidy	50	40	..	..	..	..
War expenditure	741	258	149	60	16	4
	1,584	1,180	1,053	822	800	796

Expenditures.—These liberal reductions of taxation could not be effected without substantial economies in expenditure. In 1921 a Committee with Sir Eric Geddes as Chairman made a searching investigation of the expenditure of public departments and recommended extensive savings. The foregoing table analyses public expenditure up to 1924–5 (appropriation accounts) and distinguishes ordinary from War expenditure.

The diminution of £142,000,000 in ordinary expenditure in 1922–3 is not wholly due to economy. The exclusion of Irish services relieved civil votes of about £20,000,000. The heavy fall of prices relieved expenditures not only directly, but also through the consequent reduction of the bonus dependent on cost-of-living, which is added to civil service salaries. The increase in ordinary expenditure in 1922-3 was due to the rise of £23,000,000 in debt charges, consequent on the establishment of the new sinking fund and the beginning of the payment of the American debt.

Banking

During the post-War period, and especially in the period 1918–20, the British banking system underwent a process of change which, although from the historical standpoint only a continuation of tendencies which had been in operation for many years, in fact altered the whole balance of power within the sphere of domestic banking, and altered considerably the relations which used to obtain between the sphere of the domestic banks and those operating predominantly overseas. As a consequence there arose a series of problems which were still unsolved at the end of 1925. These were the adjustment of the internal economy of the banks to the new scale of business which they were undertaking; the relations of the banks with the central bank and the money market in the technical sense; and the relations of the banks with their customers and to the national economic life as a whole.

The Amalgamation Movement.—This consisted in the process of reducing the total number of independent banks. In contradistinction to the developments in Germany, the technical form assumed by the process of concentration was exceedingly simple. Whereas in Germany a whole series of intermediate forms existed between complete fusion of banking establishments and completely independent institutions, such as the exchange of shares, pooling of resources, agreements not to invade territory, interlocking directorates and stock-ownership without the extinction of the legal existence of the firm whose shares had been acquired, the founding of subsidiary enterprises by joint action, etc.; but in Great Britain, when two banks amalgamated, the separate legal and economic existence of the amalgamating establishments ceased. Moreover, the field of operation of the British joint-stock banks was confined to England and Wales: Scottish and Irish banking being conducted under different legal codes, it was thought impossible to amalgamate such institutions with English banks: and no attempt was made, except shortly before the War, to invade the sphere of the foreign and colonial banks. It was only in 1905 that the first attempt was made by an English joint stock bank (the Midland) to open a separate branch in the City of London for the conduct of foreign operations, an example which was very soon followed; whilst in 1911 the first overseas venture of an English joint-stock bank was made when Lloyds Bank acquired the business of Armstrong and Co. in Paris.

Simple as the nature of the British amalgamation movement was, both as regards form and aim, it had sufficed to reduce very materially, even in pre-War years, the total number of separate banks. By 1910 the total number of separate joint-stock banks in England and Wales had been cut down to 45, the number having been 104 in 1890 and 77 in 1900. At the same date there were only nine private partnerships conducting a banking business—a sufficient proof of the extent to which the process of absorption by joint-stock banks had affected a transformation of banking conditions since joint-stock banking was first permitted under the Act of 1826. These 45 banks possessed between them 5,102 branches, paid-up capitals and reserves of £81,000,000, deposits amounting to £721,000,000 and outstanding acceptances to the amount of £52,000,000. At the same date the deposits of the remaining private bankers were only some £27,000,000. By 1914, the number of joint-stock banks had fallen to 38, their branches had risen to 5,869, their capitals and reserves stood at £82,000,000 and their deposits at £896,000,000, whilst the number of private banks had decreased to eight, and their deposits stood at £33,000,000. The leadership among English joint-stock banks at that date already belonged to the five banks which have since become known as the "Big Five." At the end of 1914, the deposits and numbers of offices of these banks stood as follows:—

	Deposits £	Offices
London, City and Midland	125,700,000	1,027
Lloyds	117,700,000	1,085
London County and Westminster . .	101,000,000	363
National Provincial	74,900,000	447
Barclays	167,400,000	606

Behind these leading banks ranged four large banks with deposits of over £40,000,000 each, viz.: Parrs, the Union of London and Smiths, the London Joint Stock, and the Capital and Counties, whilst five banks possessed deposits of between £20,000,000 and £30,000,000.

Home Absorptions.—The history of the amalgamation movement after 1918 is but a description of how the leading five banks completely absorbed their powerful but somewhat smaller rivals, by a process of competition among themselves. The critical years were 1918 and 1919. In those two years, to mention only the more important events, the National Provincial absorbed the Union of London and Smiths, the Sheffield Banking Co. and the Bradford District Bank: Barclays (having absorbed the important United Counties Bank in 1916) took over the just amalgamated London, Provincial and South Western Bank; the Westminster absorbed Parrs Bank and the Nottingham and Nottinghamshire Banking Co.; Lloyds Bank took over the Capital and Counties and the West Yorkshire Bank; finally, the Midland absorbed the London Joint Stock Bank. In the same years the Bank of Liverpool amalgamated with Martins Bank, and absorbed the Halifax Commercial Bank, the Palatine Bank and Cocks, Biddulph and Co., thus forming a new and powerful group, better able to stand centripetal pressure from the older and more powerful combinations. The competition to absorb did not relax in later years, and affected particularly the remaining private bankers. In 1920 the Westminster took over Beckett & Co. of Leeds; in 1923 Cox and Co., and H. S. King and Co. were absorbed by Lloyds, and Holt and Co. by Glyn Mills and Co. In the following year the old firm of Child and Co. was acquired by Glyns, and Grindlay and Co. by the National Provincial, while the Royal Bank of Scotland absorbed Drummond and Company. In the same year also the National Provincial absorbed the Guernsey Banking Co. and the Westminster took over the Guernsey Commercial Banking Co.

Affiliations and Extensions Oversea.—Even more significantly, the amalgamation movement no longer confined itself to traditional forms and areas. During and after the War, the "Big Five" converted their undertakings from unified structures to banking groups with a main stem representing the amalgamations, with branches from the main stem in the shape of affiliated and subsidiary undertakings, and with undertakings owned in common. Thus the Midland affiliated the Belfast Banking Co. in 1917, the Clydesdale Bank in 1920 and the North of Scotland Bank four years later: Barclays control two affiliated institutions, the British Linen Bank (1919) and the Union Bank of Manchester (1919), and possesses subsidiaries in the shape of Barclays Bank (Overseas) Ltd., Barclays Bank S.A.I. at Rome, and Barclays (Dominion, Colonial and Overseas) Bank. Barclays' holding of shares in the Colonial Bank and the Anglo-Egyptian Bank were turned over to the last named, formerly the Colonial Bank, with which the Anglo-Egyptian Bank and the National Bank of South Africa are amalgamated. Lloyds Bank has a footing in India through the acquisition of Cox and Co. and H. S. King and Co., is affiliated with the National Bank of Scotland and the Bank of London and South America (an amalgamation of the London and River Plate Bank and the London and Brazilian Bank), is joint owner with the National Provincial Bank of Lloyds and National Provincial Foreign Bank Ltd., and is a shareholder (as are also the Westminster, the National Provincial and Standard Bank of South Africa) in the Bank of British W Africa.

The Westminster Bank has affiliated the Ulster Bank, is a sha holder in the Royal Bank of Canada as well as in the British Ital Banking Corporation (as are also its leading competitors, Lloy and the National Provincial), and owns the Westminster Fore Bank Ltd. The National Provincial has affiliated Coutts and (1920), is a shareholder in the P. and O. Banking Corporation, a is half owner of Lloyds and National Provincial Foreign Bank. Th with the exception of the Midland Bank, all the leading institutio are interested directly in overseas banks. The tendency to be terested in such concerns has affected even the smaller joint-sto banks: thus Williams Deacons Bank and the Union Bank of Sco land are both shareholders in the British Overseas Bank, and a ve large number of concerns other than those already mentioned a included among the shareholders of the British-Italian Banki Corporation.

Effect of Amalgamations.—So vast a development as this w well calculated to attract public attention and to cause alar But, in the main, public attention and criticism have been co fined to the absorption and extinction of competing banks with the confines of the country and have concerned themselves litt with the other features of the situation, which, as a matter fact, represented a more significant breach with tradition. C March 11 1918, when the competitive amalgamation moveme was at its height, the Treasury appointed a committee on ban amalgamations to investigate the whole position. The committe reported on May 1 of the same year, but the evidence laid befo it was not made public. The committee was clearly not ver impressed by the argument that the growth in the scale of bus ness undertakings justified the latest amalgamations, and wa influenced by the view that when two banks of national scop join together, the effect is a net reduction of competition.

It thought the tendency for amalgations to reduce the ratio capital and reserves to deposits undesirable, and gave cautiou assent to the view that circumstances might produce somethin approaching a money trust at a comparatively early date. Th committee therefore recommended legislation requiring tha the prior approval of the Government must be obtained befo any amalgamations are announced or carried into effect, "i cluding under this term proposals for interlocking directorate affiliations, and in fact, any arrangements which in effect wou alter the status of a bank as regards its separate entity an control." Though no such legislation was carried, the prior con sent of the Treasury is obtained before amalgamations are car ried into effect, and Lloyds' Bank was refused permission t acquire the shares of the National Bank of India in 1919. S far as the domestic situation is concerned, Treasury control doe not appear to have affected the course of events very much.

The alarm which the movement has created is in the main du to the feeling that the absence of effective competition woul mean less ample facilities and higher charges for the public, a well as greater rigidity in the business intercourse with banks It is almost impossible to gauge how far the latter fear may hav been subsequently justified: it is perhaps also significant of th greater power of the banks that they had not, by the end of 1925 raised the rate on time-deposits to the pre-War level of 1½% below bank rate. What is undoubtedly true is that the amalga mation movement has not in any way checked competitio among the banks in the creation of new offices. These continu to increase in a ratio for which there would seem to be very little real justification.

The amalgamations of 1918–9 were undoubtedly in part com petitive: the leading banks absorbed others lest some competin bank should do so. The cost of acquisition was thus in some case unnecessarily high, but the relative smallness of British bankin capitals—a disadvantage from other standpoints—prevented thes high acquisition costs from being a very serious permanent burden A more legitimate reason for expansion was undoubtedly the feelin that the end of the War would see intensified competition betwee Great Britain and Germany, for which strong and powerful bank were needed: but whilst this was hardly a justification for the internal absorptions (in view of the already large size of the the existing banks) it was a legitimate argument as regards overseas expansion. On the other hand, the later and lesser amalgamation which accompanied the trade depression of 1921 and subsequent years re no doubt forced upon the absorbing banks by the position of the aker banks, and by the fear that a general distrust of the banking stem would arise if a series of failures were allowed to take place. Occurring at a time when all economic phenomena were affected d distorted by the War (in particular, in the case of banking ures, by inflation) it is impossible to say to what extent the actual ovements of deposits, loans, investments and advances would ve been different, had amalgamations been less frequent.

Statistics of the "Big Five" Joint Stock Bank

	At June 30							(At Dec. 31)

iscounts, Loans, Advances and Money at Call	488·8	1,077·9	1,147·5	1,064·3	1,031·4	1,037·9	1,075·8	1,090·4
over for Acceptances, Premises, Sundries	46·5	90·2	69·3	68·2	88·7	97·8	105·2	123·2
otal Assets or Liabilities	731·8	1,761·3	1,773·6	1,752·0	1,674·9	1,700·9	1,698·1	1,730·9

The most significant changes are the decline in deposits since the ximum of 1921 and the fall in investments accompanied by a rise advances and discounts. This would indicate that the banks are sponding to the needs of trade by reducing their holdings of fixed erest-bearing securities and of Treasury bills. Substantially the me results are revealed by taking the total banking figures of eat Britain, as under:—

Banking Liabilities and Assets

	Liabilities In £, millions of		
	1922	1923	1924
apital and reserves	156·2	156·1	161·4

(T. E. G.)

V. POPULATION

The decennial census due in 1921 was planned for April 24 of at year. Owing to the coal dispute then in progress the enu- eration was postponed to June 19. The total population und at this latter date may be compared with that found in 11 as follows:—

Before 1921 the decennial increase per cent had never been less than 10% for England and Wales. The number of females to 1,000 males in England and Wales, had, since the date of the first census in 1801, never been less than 1,036 (in 1821) and never, until 1921, been more than 1,068 (in 1901 and 1911). For the large excess of women in 1921 and for the unusually small increase per cent that occurred during that period, the War is in part responsible. The effect of the War can be more clearly seen when the crude birth rates and crude death rates since 1911 are considered. The crude rates are the numbers born and the numbers dying per 1,000 of the population during the year to which they refer. Deaths due to the War occurring abroad are excluded.

TABLE I. *Total Population of Great Britain*

Area	Date of Census	Persons	Population	Increase of Population since the preceding Census	Decennial increase per cent of Population	No. of Females to 1,000 Males
ngland and Wales	1911	36,070,492	M 17,445,608 F 18,624,884	3,542,649	10·89	1,068
ngland and Wales	1921	37,886,699	M 18,075,239 F 19,811,460	1,816,207	4·93	1,096
cotland	1911	4,760,904	M 2,308,839 F 2,452,065	288,801	6·5	1,062
cotland	1921	4,882,497	M 2,347,642 F 2,534,855	121,593	2·6	1,080

The effect of the War upon the death rate was to check the decline which had been in evidence previously. The influenza epidemic of 1918, which may be traced to the War, caused a high death rate that year. Since the War the death rate has declined to a lower figure than was ever shown before 1914. When the infant mortality rates for these years are considered (that is the number of children dying under one year of age per 1,000 born) it appears that the greatest improvement has been effected in the case of infants. The infant mortality rate, for instance, which in England and Wales was 128 for the period 1901–1910 and 100 for the period 1911–1920, declined to 83 in 1921, to 77 in 1922, and to 69 in 1923.

The effect of the War upon the birth rate was to cause during the progress of hostilities a more rapid decline than had been in evidence before and to cause after the end of hostilities a sudden rise to a higher figure in 1920, since when it has declined to a lower figure than was ever reached before. The decline in the crude birth rate which had been taking place for more than 50 years is mainly to be accounted for by decline in the number of children born to wives of reproductive age, but partly also by a change in the age distribution of the population. Owing to this change in age distribution there is now a smaller percentage of wives of the most reproductive ages than formerly.

These two facts may be illustrated as follows. In the period 1911 to 1915 there were 189·7 births per 1,000 wives aged 15 to 45; whereas there were in 1921, 176·5; in 1922, 161·6; and in 1923, 156·3. During the same period, however, of 100 wives

TABLE II. *Birth Rates and Death Rates: 1911–1924*

Date	Birth Rate per 1,000 of the Population		Death Rate per 1,000 of the Population	
	England and Wales	Scotland	England and Wales	Scotland
1911	24·3	25·6	14·6	15·1
1912	23·9	25·9	13·3	15·3
1913	24·1	25·5	13·8	15·5
1914	23·8	26·1	14·0	15·5
1915	21·9	23·9	15·7	17·1
1916	20·9	22·8	14·4	14·3
1917	17·8	20·1	14·4	14·3
1918	17·7	20·2	17·6	16·0
1919	18·5	21·7	13·7	15·4
1920	25·5	28·1	12·4	14·0
1921	22·4	25·2	12·1	13·6
1922	20·4	23·5	12·8	14·9
1923	19·7	22·8	11·6	12·9
1924	18·8	21·9	12·2	14·4

under 45 the proportion of wives under 35 has decreased, and this partly accounts for the decline in the number of children per wife. Thus in 1901 there were 593 wives under 35 years of age out of every 1,000 wives under 45; in 1911, 559; and in 1921, 535.

The changes in age distribution revealed by the census indicate that the proportion of young persons in the population is declining while that of old persons is increasing. There were, for example, out of every 10,000 of the population in England and Wales, 2,094 persons under 10 years of age in 1911 and 1,806 in 1921, whereas there were 297 persons of age and over in 1911 and 344 in 1921. The fact that the average of both sexes in Scotland was 28·0 in 1911 and 29·6 in 1921 illustrates a similar change in that country.

Distribution in Urban and Rural Areas.—The density of the population in England and Wales was 649 per sq. m. in 1921 and 164 per sq. m. in Scotland. The population was distributed as between urban and rural areas in the following proportions: England and Wales 79·3 % urban and 20·7 % rural in 1921, as compared with 78·1 % and 21·9 % in 1911; Scotland 77·3 % urban and 22·7 % rural in 1921 as compared with 75·4 % urban and 24·6 % rural in 1911. When making comparisons between England and Wales on the one hand and Scotland on the other in this respect, it must be remembered that owing to differences in local government between the two areas the terms "urban" and "rural" are used in somewhat different senses.

Two further points should be borne in mind when considering figures for urban and rural areas. These areas do not remain constant from census to census. Areas, formerly classed as rural, are from time to time added to the total urban area owing to changes in the organisation of local government. The population classed as urban therefore occupies a somewhat larger area at each succeeding census. Again the urban area includes many small towns and therefore not all those classed with the urban population are living under strictly urban conditions. A better picture of the urbanisation of the country is provided by the fact that 33·8 % of the population of England and Wales were in 1921 living in towns of over 200,000 inhabitants each. The concentration of population in certain areas may also be illustrated by the fact that out of the 53 counties in England and Wales the 12 most populous counties contain 67·1 % of the population while the 7 most populous of the 33 counties of Scotland contain 71·9 % of the population.

Another method of illustrating the same point is to calculate the proportion which each county respectively contributed to every 100,000 of the population in 1921. It is then found that Lancashire contributed 13,007, London 11,838, Yorkshire 11,041, Durham 3,905, Essex 3,881, Warwickshire 3,669, Staffordshire 3,560, Middlesex 3,307 and Glamorganshire 3,305. Eight counties in England and Wales show an actual decrease in total population between 1911 and 1921. They are Cornwall, Herefordshire, Montgomeryshire, London, Rutlandshire, Westmoreland, Cardiganshire and Merionethshire. London as a whole, it may be noticed, has increased, the increase having taken place outside the county administrative area. In Scotland 17 of the 33 counties show decreases within the same period. Every county in England and Wales shows an increase in total population between 1801 and 1921, but in Scotland five counties, Argyll, Berwick, Orkney, Perth and Sutherland, had in 1921 fewer inhabitants than in 1801.

The most populous towns of England and Wales in 1921 were as follows:—

London (administrative county) .	4,484,523	Sheffield . .	480,639
Birmingham . .	919,444	Leeds . .	458,232
Liverpool . .	802,940	Bristol . .	376,975
Manchester . .	730,307	West Ham . .	300,860

In Scotland the most populous towns in 1921 were:—

Glasgow	1,034,174
Edinburgh	420,264
Dundee	168,315
Aberdeen	158,963

In England and Wales there were 46, and in Scotland four towns each with more than 100,000 inhabitants.

Distribution by Occupation.—The first use which can be made of the information collected at the census regarding occupation is to classify the population according to industrial status. Table III. illustrates the result.

The number of women recorded in Table III. as "gainfully" occupied is relatively small because most women not "gainfully" occupied are married and household duties are not included in in the term "gainful" occupations. Of the 10,542,599 women in England and Wales for instance, in 1921 over 12 years of age, who were not "gainfully" occupied, 6,886,931 were married.

TABLE III. *Industrial Status of Persons Gainfully Occupied, 19*
12 Years of age and over

Industrial Status	England and Wales		Scotland	
	Males	Females	Males	Females
Employers .	563,203	73,708	88,745	9,445
Employees .	10,800,276	4,664,603	1,354,078	584,096
Working on own account . .	749,239	327,021	91,996	39,244
	12,112,718	5,065,332	1,534,819	632,785

The population may next be classified according to the occup tions followed. The chief occupations in England and Wales and Scotland respectively were as follows:—

TABLE IV. *Chief Occupations by Sex, 1921*

Occupations of Males	Total in each Occupation	Occupations of Females	Total in each Occupation
England and Wales			
Metal working .	1,540,235	Personal service .	1,676,42
Transport and communication .	1,420,593	Textile workers .	608,96
Agriculture . .	1,171,298	Makers of textile goods and dress	548,01
Commerce and finance . .	1,063,120	Commerce and finance . .	496,05
Mining and quarrying . .	1,061,749	Clerks and typists . .	429,69
Clerks and typists	568,034	Professional . .	359,98
Scotland			
Metal working .	280,210	Personal service .	168,14
Agriculture . .	169,984	Textile workers .	92,40
Transport and communication	169,912	Commerce and finance . .	83,11
Mining and quarrying . .	151,884	Makers of textile goods and dress	53,96
Commerce and finance . .	116,460	Clerks and typists . .	67,96
Workers in wood and furniture .	80,860	Professional . .	44,97

Since a new classification by occupation was used in 1921, co parisons with former censuses cannot easily be made. It should remembered that this classification is by occupation and not by dustry. It might with care make possible a rough estimate of t numbers engaged in sedentary and non-sedentary occupation, skilled and unskilled occupations and similar comparisons. It d not show the numbers engaged in different industries. Thus cleri workers are placed in a separate group. If all such workers are al cated to the industries with which they are usually associated, it possible to classify the population by industry. This is done in t following table.

TABLE V. *Chief Industries, 1921*

England and Wales		Scotland	
Industry	Total in each Industry: Both Sexes	Industry	Total in each Industry Both Sexes
Commerce and finance . .	2,275,148	Commerce and finance . .	289,369
Manufacture of metals . .	2,196,014	Manufacture of metals . .	368,610
Personal service .	2,046,825	Personal service .	199,648
Public administration and defence	1,335,879	Agriculture . .	183,086
Mining and quarrying . .	1,283,728	Mining and quarrying .	179,95
Transport and communication	1,203,566	Transport and communication	155,564
Manufacture of textiles . .	1,153,829	Manufacture of textiles . .	151,16
Agriculture . .	1,123,962	Public administration and defence	143,19

The precise scope of the industries included in the above ta requires careful examination if the figures are to be properly app ciated. Thus commerce and finance includes persons engaged in

of wholesale and retail dealing, in auctioneering and valuing
ll as in banking and insurance. Shop assistants therefore form
e part of the total in this group. The manufacture of metals
les also the manufacture of machines, implements, conveyances,
ery and watches. Personal service includes not only domestic
e but also service in lodging houses, hotels, clubs, laundries and
irants. Public administration and defence includes, in addition
fighting services, those employed both by local and central
nment authorities. Transport and communication includes
employed in connection with storage. The manufacture of
es includes not only those engaged in the manufacture of cotton,
and silk goods but also those engaged in the manufacture of
us miscellaneous products such as lace, carpets, rope, asbestos,
and tarpaulins, as well as those engaged in dyeing, printing,
hing and calendering.

ien the population is thus classified, it is seen that those en-
l in certain industries are less in number than those engaged in
orresponding occupations. Those engaged in the transport in-
y, for example, are fewer in number than those engaged in the
ation of transport and this is so because some of those who
transport as an occupation appear in the industry table as
ging to another industry. Thus while a railway man would
ir among those engaged in transport both as an industry and
occupation, a carter employed by a mining company would be
d as following the occupation of transport but belonging to the
try of mining. Those who follow the occupations of mining
griculture comprise nearly all those who are engaged in the cor-
nding industries, whereas those engaged in commerce and finance
occupation only form about half of those engaged in the corre-
ling industry owing to the fact that numerous clerical workers who
v the clerical occupation belong to the industry of commerce
inance. Four of the eight chief industries are not industries in
veryday meaning of the term, namely, commerce and finance,
nal service, public administration and defence, and transport
communication. If they are omitted from consideration, the
try of the manufacture of metals takes the first place in Great
in.

e low place of agriculture is noteworthy. It was once considered
rkable when those engaged in agriculture were less numerous
those engaged in all other industries taken together. Agricul-
s now not even the most important industry from the point of
of numbers, having fallen to the fourth place in England and
s and to the second place in Scotland. It is possible to classify
tries broadly into those which are extractive, manufacturing,
butive and certain miscellaneous groups. If agriculture, mining
ishing are regarded as extractive and commerce and finance
ransport and communication as distributive, then the following
is obtained. In England and Wales of all those engaged in in-
y, those engaged in manufacture comprise 43·6%, in distribu-
20·3%, in extraction 14·0%, in personal service 11·8%, in
c administration and defence 7·7%, in professions 2·9%, in
and entertainment ·7%. In making this calculation the
67 persons engaged in the gas, water, electricity industrial
have been included among those engaged in manufacture. It
d be noticed that about 60,000 of them are employed by local
rities and that a certain percentage of all those in this group
d more properly be included among those who are engaged
work of distribution.

using.—For the purpose of the census a structurally separate
ing is defined as any room or set of rooms having separate
s to the street or staircase. Thus a flat is such a dwelling. In
ting the number of rooms, sculleries, bath rooms, shop or
rooms are excluded. The total number of dwellings was found
7,759,821, having a total number of 39,894,618 rooms. There
thus an average of 5·14 rooms per dwelling in England and
s, but as some dwellings were occupied by more than one family
were only on the average 4·55 rooms per family. As the average
er in a family was 4·14 the average number of rooms per person
1·1. But these averages by themselves give little or no idea of
ctual housing conditions of the population. Thus there were no
than 3,480,273 private families with less than ·5 rooms per
n, while there were 17,429,709 persons belonging to families
less than one room per person. Again 9·6% of the total private
y population was living with more than two persons per room
ngland and Wales. Judged according to this standard the
ties vary greatly. London has 16·1% of the population living
more than two persons per room while Cornwall has only 2·8.
figures, however, take no account of the size of the rooms.
ing statistics tend to show a progressive improvement when the
ns of one census are compared with those of preceding censuses,
gh the figures for 1921 exhibit a check to the rate of improve-
. The following figures for Scotland show the number of
pied houses per 100 of the population: 1881, 19·8; 1911, 21·3;
921, 21·7.

rital Conditions.—Of the male population in England and Wales
21 55% was single, 41·4% married and 3·6% widowed. Of the
e population 53% was single, 38·3% married and 8·2%
wed. The large number of widows, 1,621,658, is noticeable,
nting to nearly three times the number of widowers. There
at this date 8,464 men and 8,218 women divorced.

Language.—The census returns show that the use of Welsh and Gaelic is declining. The proportion of persons three years of age and over in Wales and Monmouthshire speaking Welsh only was 85 per 1,000 in 1911 and 63 per 1,000 in 1921, while in Scotland the proportion of those speaking Gaelic only was 4·56 in 1911 and 3·47 in 1921. The proportion of those speaking both English and Welsh and English and Gaelic has also declined.

VI. INDUSTRY AND TRADE

The period of 1910–3 was one of steadily improving trade, but during the first seven months of 1914 there was a perceptible decline of prices and employment.

The War Period.—The principal effects of the World War were the alteration of the normal directions of foreign trade, owing to the interruption of commerce between the belligerent nations and the influence of blockage policies on the commerce of neutral countries; the gradual assumption of control by the Government over both production and distribution; the diversion of production and distribution; the diversion of production into new channels for the supply of War requirements and to make good the loss of imports due to the interruption of commerce; and great changes in labour conditions.

Government Control.—The progress of control by the Government is thus described in the Report of the War Cabinet for the year 1917 (Cmd. 9005, p. 130).

> As the military struggle developed in scope and intensity, and the necessity of concentrating national efforts on the War became more pressing, section after section of industry was taken over, and wages, prices and profits, from raw material to finished product, were placed under Government control. The process of extending State control, taking over more works and applying it to an always widening range of products, continued unbroken right up to the end of 1916. Whilst no exact demarcation line can be fixed, if a broad definition of the character of the movement to that period were attempted it would be that industries essential to War needs had been taken under Government control whilst industries serving the civil population were still left in private hands. In the same way 1917 may be described as the year in which State control was extended until it covered not only national activities directly affecting the military effort but every section of industry—production, transport and manufacture.

Towards the end of June 1917 the country was faced by a serious crisis in the cotton industry, owing to the difficulty of securing supplies of raw cotton. With the co-operation of the industry, a cotton control board was set up. The production of the cotton mills was cut down to 60%, extensions only being allowed on payment of levies, and the sum thus raised utilised for the benefit of the work-people in the less employed mills. The control board thus established contained representatives of the employers and the employed and also of the Government.

A board of control on somewhat similar lines was set up for the wool textile industry, to deal with the difficult problems which arose from the fact that, after Government requirements had been met, rather less than 20% of the output of the trade was left for civil needs. According to the War Cabinet Report for 1918 (p. 210), there was no question raised in connection with the wool textile industries to the solution of which the board did not contribute a most valuable part. Somewhat similar arrangements were made for the jute, flax and hemp industries.

One important effect of the Government control and of the strain put upon various industries by War conditions was the attempt made to extend the standardisation of production even into the clothing industries. By the end of 1918 there had been put on the market £15,000,000 worth of standard suits, over 2,000,000 lb. weight of hosiery, 1,000,000 blankets and 8,000,000 pairs of standard boots. These schemes of standardisation did not long survive the end of the War, though they may have led in some degree to simplification and the reduction of patterns. Of more lasting effect was the great alteration brought about in the productive capacity of various industries.

The manufacture of explosives and propellants was chiefly carried out in special Government factories, but shell cases, rifles, guns, trench weapons, aircraft, tanks, etc., could be produced in different classes of engineering works, and the engineering industry of the country was by degrees almost entirely absorbed in this work, which led to a very considerable expansion of engineering capacity. The same cause brought about a 50% expansion of capacity in the iron and steel industry, and varying increases in many smaller industries.

Various new industries had to be created to supply essential products which were formerly imported from sources rendered unavailable by the War. Amongst these may be mentioned dyestuffs, a large range of fine chemicals, optical and scientific instruments and their components, and various special products such as magnetos. A special Act (The Dyestuffs [Import Regulation] Act 1920 [10 and 11 Geo. V., Ch. 77]). was passed in 1920 prohibiting the importation of dyestuffs except under licence, the idea being gradually to build up by these means British production of essential dyestuffs. In 1921, the Safeguarding of Industries Act (11 and 12 Geo. V., Ch. 47), subjected to an import duty of 33⅓% a wide range of the other articles mentioned above.

War conditions brought about:—

(*a*) Changes in wages, (*b*) new methods of negotiation and relations between employers and employed, (*c*) the introduction of new processes and spread of repetition work, (*d*) improvement in the position of unskilled relatively to skilled labour, (*e*) an enormous increase in the industrial employment of women and (*f*) an increased interest in the improvement of methods of production and the welfare of workers.

Prices and Wages.—The complete control assumed over various industries fixed on the State the responsibility for the control of wages. The cost of living rose steadily during the War (from 100 in July 1914 to 205 in July 1918), and as the demand for War material was practically unlimited the adoption of the cost of living as a standard in the fixation of wages was almost inevitable. This principle was, however, not universally adopted, nor was there any generally accepted decision as to whether the increase should be a flat rate for all workers (on the ground that all need approximately the same minimum amount of food, clothing, etc.), or a rate proportional to earnings or varying inversely with earnings. The method generally adopted by the Government in the controlled industries was, however, to give a flat rate War wage.

This principle had the very important effect of introducing a change in the relation between skilled and unskilled labour, the position of the unskilled being very greatly improved. The following summary by Professor Bowley of the progress made from 1914–20 may here be quoted:—

> After a few months of unsettlement the demand for War materials and the withdrawal of men to the Army resulted in very plentiful employment. The opportunity of increased family earnings at former rates of pay together with an active patriotic spirit prevented for some time demands for increased wages. As food became scarce and prices rose, however, earnings became insufficient in some cases to meet the reasonable needs of efficient subsistence, and bonuses and War wages were given, while the great demand for labour had its natural effect in raising rates of wages. So far as generalisation is possible, we may state that the growth of rates of wages generally lagged behind that of prices, but earnings, in those very numerous cases where piece rates or overtime gave facilities for additional work and pay, increased more rapidly than prices from the outbreak of the War to the Armistice. In the early part of 1919 the War rates continued, though earnings probably tended to fall; and the working classes, fairly content with existing rates in view of the slight fall in prices, devoted their attention to reduction of hours, so that in fact the normal working week was generally reduced by some 10%, while the same money was received for the shorter week as formerly for the longer. When the rise of prices set in again there were continued further upward movements of wages, and at the same time several of the more powerful trade unions made definite efforts to secure a higher standard of living than before the War, while the principle of a minimum wage, intended to be sufficient to allow a livelihood more liberal than had been customary, was widely applied. The re was that during 1919 and 1920 there was a race between wages prices.

With regard to the employment of women, the follow figures sufficiently illustrate the position:—

Average figures for men and women in industrial employment (manufacturing)

	July 1913	July 1918	July 192
Men	6,301,000	5,058,000	6,016,90
Women	2,178,600	2,970,600	1,987,99

The end of the year 1920 marked the peak of prices, and slump of 1921 came upon a chaotic wage position. In s classes of work real wages were higher than pre-War, bu others they were lower. Railway workers, coal-miners, dock and others had definitely obtained improvements in their sta ard of living. The effects of War tendencies continued in va ing degrees in different industries, sometimes without consideration for what the commercial conditions enabled industry to sustain. Moreover, the operation of foreign com tition upon certain industries created a great disparity betw wages in these industries and those in the non-competitive sheltered industries (covering about one-half of the total sons employed), and it is the general view of industrialists t the high level of these latter wages added a very considera burden of cost to the less fortunate industries and seriou hindered their revival. (*See* PRICES; WAGES.)

Industrial Relations.—The experience of such bodies as cotton and wool control boards, the spirit of comradeship gendered by the War, and the strengthening through War perience of the nation's realisation of the dangers of indust strife, created a new attitude towards the relations betw employers and employees. This found expression in individ works in the growth of works committees and other co-operat methods, and nationally in the establishment of the scheme joint industrial councils, recommended by what is known as Whitley Committee's Report. Of these there were by the of the year 1921 between 50 and 60 in operation, covering s important industries as wool and allied textile, heavy chemi printing, pottery, flour milling and gas and electricity supp

The fact that the scheme was not adopted in coal-mini cotton, engineering, railways, iron and steel, and certain ot industries was largely due to the existence in those indust of well-tried conciliation schemes, which neither party desi to change. The intention of the scheme was that the coun should include in their scope not only conciliation but a w range of subjects of general interest to the industry, such technical education, etc. This intention has only been very p tially carried out. Another evidence of the new spirit was foundation of such bodies as the National Alliance of Employ and Employed (now called the National Industrial Allianc the Industrial Welfare Society; the Institute of Industr Psychology; the Industrial Fatigue Research Board, bod which still survive to carry on the useful work indicated their titles. (*See* INDUSTRIAL RELATIONS.)

Scientific Research.—The War strongly stimulated a m beneficial movement for scientific research. In 1917 Parl ment voted a sum of £1,000,000 to be administered by a spec committee of the privy council in grants to trades willing form research associations. In 1924, 23 industrial resea associations were in actual operation, and the privy council co mittee was able in its report for 1923–4 to record the opini that the scheme promised to be a marked success. There h also been a substantial extension of research work by individu firms. (*See* INDUSTRIAL RESEARCH.)

Trade Organisation.—Shortage of raw materials and oth factors made it absolutely necessary for the Government, wh handling industrial questions, to be able to deal with trades a whole. This led to the formation of voluntary representati associations in a considerable number of industries, while t increased realisation on the part of industrialists of the imp tance of mutual consultation and co-operation for commerc oses led to the foundation in 1916 of the Federation of ish Industries, a strictly non-political body dealing solely commercial questions.

ne tendency towards amalgamation of individual firms was much stimulated by War experience and by the recom- dations of Government committees, which brought home dustrial leaders the necessity of safeguarding supplies of material, enlarging the scale of production, etc. The ar- nent firms, faced with large extensions of plant, sought to itate the employment of these after the War by the acqui- n of subsidiary businesses, capable of acting in the capac- f suppliers of material or buyers of partly finished products. e were also considerable amalgamations in the iron and electrical engineering, in cocoa, chocolate, biscuit and glass stries. The formation of a large combine in the jute trade 920 may also be mentioned, but there was not any very ral enlargement of units in the textile industries. These ous amalgamations have not all been equally successful.

rade Development.—Owing to changes in values and methods cording it is difficult to compare post-War trade with that 913. The following chart and tables show the course of trade e United Kingdom and in certain specified industries. Fig- are for the whole of the British Isles up to April 1 1923, and Great Britain and Northern Ireland after that date. The quantity index has been compiled to compare the post-War overseas trade with that for 1913.

Overseas Trade of the United Kingdom in value and volume, 1913, and 1919 to 1925

1. IMPORTS

Year	Food, Drink and Tobacco		Raw Materials and Articles mainly unmanufactured		Manufactured Articles		Total	
	Mill. £	Index of vol.	Mill. £	Index of vol.	Mill. £	Index of vol.	Mill. £	Index of vol.
1913	295	100	270	100	201	100	769	100
1919	719	93·9	607	96·1	296	63·2	1,626	86·4
1920	766	90·1	710	91·8	453	81·8	1,932	88·4
